personally verify, only having come in contact with established trees. Perhaps any reader who has planted it will kindly give his experience. The specimen here either received a severe check, or had its leader crippled comparatively early in its career. It runs up to a height of 12 feet, with a bole whose diameter does not lessen greatly from the 18 inches measured close to the ground. At this height, however, the thick bole comes abruptly to an end, and half a dozen leaders or perpendicular branches spring from it which form the head of the tree. The height is 38 feet. In general appearance the tree reminds me very much of one of the grand old standard Pears to be found occasionally in south country orchards, save that, never having been touched by knife or saw, there is a density of small growth in the Salisburia that is lacking in the Pears.—E. BURRELL, *Claremont*.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

MARCH 12.

THE meeting on Tuesday last in the Drill Hall afforded a most singular contrast to that of the previous gathering. On all sides there was a marked increase, notably amongst Orchids, which were by far the most numerous of the exhibits, it being, as it were, a field day for the early-flowering Dendrobies, of which some of the best known kinds were staged, both of hybrids and species. To one of the former a first-class certificate was deservedly awarded. In *Dendrobium Apollo* we have a remarkably fine hybrid of the first rank. Quite in contrast as it were, another and similar award was made to *Sophranitis grandiflora*, an Orchid that has for many years been a general favourite, and no award ever made was more deservedly given; the plant itself was a splendid example of successful cultivation, and for that alone was worthy of note. Another and old favourite was present in *Dendrochilum glumaceum* (syn., *Platyelinis glumacea*), a most profusely flowered specimen. Before the floral committee came several good exhibits, notably that of the new China Rose Duke of York, another Waltham seedling which bids fair to be a most valuable decorative pot Rose both for late autumn and early spring. The plants in question were well flowered, the foliage of medium size and the growth dwarf. Several well-flowered plants of *Camellias* were also contributed, likewise a choice selection of cut blooms. *Hemantus Kalbreyeri* was shown in fine form, proving its utility as an early-flowering bulbous plant of showy character. Of early *Daffodils*, forced, of course, but none the less welcome, there was a good display, and the best forms of the *Snowdrops* were to be seen in good character. The delightfully fragrant *Boronia megastigma* made its first appearance. Some few decorative plants of general character were likewise staged. At this season it could not be expected that any great number of exhibits would come before the fruit committee, but a considerable amount of interest was evinced in a new Strawberry now shown for the first time, one that bids fair to eclipse all other sorts for early forcing both for private consumption and the market also. The fruits are of large size and of good flavour for the season, the growth dwarf and compact, and the cropping qualities excellent. An exhibit of Figs from Syon House proved the value of the variety (St. John) for early forcing, the fruits in question having been part of a very heavy crop from a pot plant.

#### Orchid Committee.

First-class certificates were awarded to—

*SOPHRANITIS GRANDIFLORA*, of which quite a unique plant was shown bearing some five dozen or more of its showy flowers, these being of brilliant colour and large in size. This large healthy mass was growing in a shallow pan. It was first introduced from the Organ Mountains, of

Brazil, in 1837. From Sir Trevor Lawrence's collection.

*DENDROBIUM APOLLO GRANDIFLORUM* (*D. nobile pulcherrimum* × *D. Ainsworthi splendidissimum*).—A remarkably fine hybrid raised between two very superior varieties, with flowers as large as in *D. nobile nobilium*, but more expanded, the sepals and petals being of a deep vinous purple, shading off at the base, the lip tipped with the same bright tint, with a large maroon-purple blotch broadly margined with white, and fully 1½ inches in width, the growth very robust and free. From Mr. James Cypher, Cheltenham.

Awards of merit were voted to—

*DENDROBIUM EPOSUM VIRGINALE*.—A charming hybrid of delicate beauty raised between *D. nobile intermedium* and *D. endocharis*, the latter itself being also a hybrid. The sepals and petals are of a delicate pure white, the lip somewhat elongated, ground colour white with a soft purple blotch, the growth dwarf and compact. From Messrs. J. Veitch and Sons.

*LÆLIO-CATTLEYA MYRA* (*Lælia flava* × *C. Trianae*).—A very distinct and beautiful hybrid, having the habit in a large measure of *L. flava* with the flowers of intermediate size, the sepals and petals of the palest primrose with the labellum of a pale yellow, deeper at the base. In its colour this hybrid stands by itself, having none of the brilliant tints of *C. Trianae*, whilst that of *L. flava* is greatly subdued. From Messrs. J. Veitch and Sons.

*PHAIUS-CALANTHE HERORATA ROSA* (*Calanthe vestita gigantea* × *Phaius grandifolius*).—A hybrid in which the vigour displayed by both of its parents has been greatly reduced, resulting in quite a dwarf growth, but still retaining the characteristics of the latter, the spike also being erect, but with flowers of the form of those of the *Calanthe*; colour a soft rosy pink, very distinct. From Messrs. J. Veitch and Sons.

*CYPRIPEDIUM FOWLERIANUM* (*C. Harrisianum superbum* × *C. bellatulum*).—An extra fine hybrid with broad petals beautifully marked, the dorsal sepal being large and, like the petals, of good form. The lip takes after *C. bellatulum*, but is larger, the colouring throughout dark claret on a lighter ground, the dwarf growth of *C. bellatulum* having given place to the freedom and vigour of *C. Harrisianum*. From Messrs. Sander and Co.

*DENDROBIUM CASIOPE ASHWORTHI* (*D. nobile albidiflorum* × *D. japonicum*).—A very pleasing and distinct form, with pure white wavy sepals and petals. The lip, which is elongated and somewhat narrow, has a pale purple blotch near the throat on a light ground; a choice hybrid. From Mr. E. Ashworth, Harefield Hall, Cheshire.

*CATTLEYA PERUVIALLANA MAGNIFICA*.—One of the very finest forms of this beautiful winter-flowering species, the labellum unusually broad and finely fringed, crimson-purple in colour, deeper at the base, the sepals and petals showing deeper tints also. From Mr. F. Hardy, Ashton-on-Mersey.

Messrs. Sander and Co. had a choice group with a profusion of flower, prominent amongst which was a trio of hybrid *Phaiuses*, each distinct and very beautiful. In all instances *P. tuberosus* was one of the parents, but its somewhat delicate constitution had disappeared under the influence of the other parent in each instance. *Phaius Cooksoni* (named after its raiser) is from *P. Walliehi* and *P. tuberosus*, having flowers of a dark terra-cotta pink, with a richly-marked lip. *P. Marthe* (*P. Blumei* × *P. tuberosus*) has the lightest-coloured flowers, a soft, pale terra-cotta shade with a large lip, finely fringed and veined; and *P. amabilis* (*P. grandifolius* × *P. tuberosus*) is intermediate in colour between the two former, with flowers of large size, the lip being especially handsome in its markings. The last two are both hybrids of the firm's own raising. In the same exhibit were *Maxillaria sanguinea*, with grass-like growth, having the dark flowers nestling near the small bulbs; *Pescatorea Lehmanni*, with one good bloom; *Dendrobium O'Brienianum*, a singular looking species; *Vanda teres alba*, a choice

form bearing three fine blooms, one particularly large; *Dendrobium nobile murrhinianum*, a beautiful form, with transparent flowers flushed with the palest purple; *D. nobile albidiflorum*, a pure white variety with dark maroon blotch on the lip, the purple tints being absent; *D. nobile nobilium*, still the finest variety, with very large richly coloured flowers; *D. Dominionum*, one of the oldest hybrids, showing *D. Linawianum* and *D. nobile* in its parentage. *D. nobile*, a very fine form, with flowers of the shape of those of *D. Wardianum*, but with the colouring of *D. nobile*; *D. Leechianum*, a near ally to, but distinct from *D. Ainsworthi*, being the result of the same cross, and *D. Ainsworthi* were also shown. *Lælia Oweniana*, with creamy white sepals and petals, also lip, save a deep violet-purple margin; *Cyclogyne Sanderiana*, a beautiful dwarf species; *Lycaste Skinneri*, of rich colour; *Cattleya Trianae virginalis*, a charming pure white form of great beauty, and bearing large, massive flowers; *Cypridium miniatum*, distinct in its large dorsal sepal, with broad margin of pure white; *Cattleya albanensis superba*, a species of distinct character; *C. Schilleriana*, one of the finest dwarf species, with broad lip veined with rich velvet-purple, quite in contrast to the bronzy copper-coloured sepals and petals; *Cypridium Crossianum aureum*, a golden form; *C. Youngianum* and its form *superbum*, both fine hybrids, notably the latter, with its handsome drooping sepals, were also included (award silver Flora medal).

Messrs. B. S. Williams and Son had an attractive group, prominent amongst which were several finely-flowered plants of *Cyclogyne cristata alba* with long spikes of bloom. Other good things included the old, but beautiful *Cymbidium Devonianum*; *Lycaste fulvescens*, well flowered, somewhat in the way of *L. lanipes*; *Cypridium Boxallii atratum*, beyond doubt the best form, the dark spots, notably in the dorsal sepal, being the distinctive feature. *C. Chamberlainianum* was shown here in vigorous growth, with richer-coloured flowers than usual. *C. Morganii*, with two spikes bearing three fine blooms on each, stood out prominently. *C. Williamsi*, one of the older hybrids, with *Dendrobium Wardianum* and *Angraecum citratum*, were also included (award silver Banksian medal). Sir Trevor Lawrence showed a most interesting group, comprising fine forms of *Calanthe Regnieri*, as *Stevensi* and *Sanderiana*, both beautiful and distinct. *Dendrobium nobile murrhinianum* was also shown here, also a singular-looking Orchid, *Ornithodium Lawrenceanum*, of scandent growth and with *Maxillaria*-like flowers. *Cypridium Lawrellii*, a fine dark hybrid; *Epiphrontis Veitchei*, a choice hybrid; *Epidendrum Endresii-Wallisi*, another well-known Veitchian hybrid; *Masdevallia Fraseri*, dark crimson, with darker veins; *Sophranitis grandiflora*, already alluded to; *Cochlioda vulcanica grandiflora*, intensely dark in colour; *Spathoglottis Lobbi*, pale yellow, most beautiful; *Eulophiella Elizabethae*, bearing one spike; *Pleurothallis Roezli*, with blackish-looking flowers, singular and distinct; *Phaius Cooksoni*, a good example, and *Dendrobium melanodiscus*, were also shown (silver Banksian medal). Mr. E. Ashworth showed five well-flowered *Dendrobiums*, *D. splendidissimum grandiflorum* being extra fine, with growths fully 4 feet in length, bearing unusually large flowers; *D. Linawianum*, profusely flowered and of good colour; *D. Cassiope* (Ashworth's var.), already noted, and *D. Findleyanum album*, a pure white form with golden blotch on the lip (silver Banksian medal).

Messrs. J. Veitch and Sons showed several of their hybrid Orchids, amongst which was the beautiful *Chysis Cheltoni*, rich in colour and very distinct, the plant bearing a sturdy spike. *Cymbidium eburneo-Lowianum* was again shown and in very fine condition, having as many as six flowers to the spike and these of extra size. *Dendrobium Edithae* (*D. nobile nobilium* × *D. aureum*) is a hybrid that partakes somewhat of *D. splendidissimum*, but has a deeper tint in its flowers. *D. Cybele nobilium* (*D. nobile nobilium* × *D. Findleyanum*) has the colour of the former

parent in the sepals and petals with the form of the latter, more particularly in the lip, which has a dark blotch. *D. Ainsworthi* intertextum is a form with pale creamy white sepals and petals, the dark spot on the lip being surrounded with pale sulphur. *D. splendidissimum* Lecanum was also shown, and likewise *Epidendrum Endresii-Wallisi*, with *Cypripedium lanthe*, a hybrid showing traces of *C. villosum* and *C. Harrisianum*. *C. Sedeni candidulum* was unusually fine and pure in colour, bearing several large blooms. *C. Lathamianum* completed this exhibit, it bearing fine flowers (silver Banksian medal). Messrs. Low and Co. had an effective group consisting of *Dendrobium splendidissimum* and *Odontoglossum Edwardi*, with several lovely examples of *O. Reezii* and *O. Roelzii album*, in the culture of which this firm excels. The plants in question bore very fine flowers. *Cypripedium Chamberlainianum* was also included, also *C. Wm. Lloyd*, a dark hybrid of *C. bellatulum* character. There was also a large plant of *Oncidium macranthum* Lowi bearing a number of flowers, as well as *Lalia harpophylla* and *Dendrobium Barberianum* with *Cattleya Trianae* (silver Banksian medal).

Of other and smaller exhibits the following are the chief: From Mr. Hamar Bass, M.P., came three well-flowered healthy plants of *Eulophiella Elizabetha*, bearing fine spikes of bloom, pearly-white and of wax-like substance, with a tint of rosy-purple on the reverse of the petals, more pronounced on the flower-stems. There were as many as eighteen flowers and buds on the spike in one instance, half of which were expanded, the three plants bearing four spikes. Mr. Cypher had *Dendrobium Ainsworthi*, Cypher's var. (*D. nobile elegans* × *D. aureum*), with much larger blooms than in the original hybrid, these being of a deeper tint, with a very robust growth. From Baron Schroder's collection came a grand spike of *Odontoglossum crispum nobiliss*, a very superior and richly marked form. *O. luteo-purpureum* and *O. Andersonianum* were both staged in fine condition, one variety of the latter being a superb form. *Dendrobium nobile Ballantianum*, a very choice and distinct form, with other good things was also included. Mr. Cobb showed *Dendrobium Schroderianum* (Dulcote var.) with bright purple flowers; also *Phaius Cooksoni*, bearing a very robust spike of nine flowers and buds.

Sir F. Wigan showed a grand specimen of *Platyclinis glumacea* with several dozen of graceful drooping spikes of its small, but fragrant blossoms—a fine cultural example; also a hybrid *Cypripedium* of distinct features. From Mr. Ingram, Elstead House, Godalming, came *Cypripedium Refulgence* (*C. Curtisi* × *C. hirsutissimum*), which showed the preponderating influence of the latter parent; and from Mr. J. Gurney-Fowler came some very superior forms of *Cattleya Trianae*, notably a dark variety with a rich velvety crimson lip. Mr. Hollington, Forty Hill, Enfield, showed one of his hybrid *Cypripediums* named *Ruth Ayling*, a cross between *C. niveum* and *C. Argus*. Mr. Thomas Statter had *Dendrobium splendidissimum* Lecanum in good condition, also cut blooms very fine in colour of *D. nobile nobiliss*, as well as *Cypripedium Phioe* (*C. levigatum* × *C. bellatulum*), the latter parent being most in evidence, and another very dark hybrid called *C. atrobens* bearing a twin-flowered spike. Mr. Craven, Ashlea, Ashton-on-Mersey, had a very fine example of *Dendrobium Wardianum albiflorum* of extra vigour, one bulb being at least 5 feet long and well flowered. Mr. Fred. Hardy showed *Cymbidium eburneo-Lowianum giganteum*, a markedly superior form of this unique hybrid, showing also great vigour of growth. *D. splendidissimum* Lecanum was also shown here, also another hybrid *Dendrobe* between *D. nobile* and *D. Findleyanum*, showing much of the latter. Two good examples of *Odontoglossums* were also included, each with a long spike. From Mr. Forster Alcock came *Cypripedium Harrisianum*, *Brassia Martiana*, and *Dendrobium undulatum*. A small group was staged by Mr. McArthur, of Maida Vale, composed of *Dendro-*

*biums*, *Cypripediums* and *Odontoglossums* in season. Mr. Lucas, Warnham Court, had very fine and long spikes of *Dendrobium undulatum*, a beautiful species with flowers of old gold colour. To this a botanical certificate was awarded, it being also included in Mr. Forster Alcock's exhibit. Mr. Lucas also received the same award for *Celogyne sparsa*, a small-growing but very pretty species in the way of, but dwarfer than *C. ocellata*. *Cochlioda vulcanica* (Warnham Court var.) was represented by a healthy plant bearing two spikes of large, deeply-coloured blossoms. Mr. Barton, Highfield, Wilmslow, sent a very fine spike of *Phaius tuberosus* with five large blooms.

#### Floral Committee.

Awards of merit were given to the following:—

**AMARYLLIS PRINCE EDWARD.**—This is a very fine kind, having a bold, well-formed flower of a deep crimson colour, shading to dark red in the throat. The green shading in the throat of the flower, which is more or less prominent in most varieties, was not visible. Exhibited by Messrs. Veitch and Sons.

**AMARYLLIS MRS. MONTEFIORE.**—This has an immense flower of fine form, the colour white, with slight feathered shadings of pale red down the centres of the petals. This also came from Messrs. J. Veitch and Sons.

**VIOLET PRINCESS BEATRICE.**—This handsome Violet is evidently possessed of great vigour, the flower large, well shaped, and borne upon a long stout spike. The colour is of a rather light shade. The scent did not appear to be very powerful. Exhibited by Mr. G. Nobb, Royal Gardens, Osborne.

**EUCARIS STEVENS.**—This, figured and described in THE GARDEN, August 11, 1894, is very free flowering, some of the plants in the group shown being merely single bulbs in small pots, but carrying a noble spike of flowers. Exhibited by Mr. P. Blair, The Gardens, Trentham.

**AZALEA JOHN WEATHERS.**—This, one of the Ghent varieties, has bold trusses of large flowers, the colour a soft shade of rosy-pink and orange. Exhibited by Mr. J. Fitt, Panshanger Gardens, Herts.

Messrs. William Paul and Son, of Waltham Cross, Herts, exhibited a group of *Camellias* in pots, and *Rose Duke of York* also in pots. The *Camellias* were medium sized, freely-flowered specimens of most of the older kinds. They also showed six boxes of cut *Camellias*, the flowers fresh and fine in colour. A large basket of *Clematis indivisa lobata* formed the centre of the group, the plants perfect wreaths of bloom. A silver-gilt Flora medal was awarded. Messrs. Barr and Son had a group of cut *Daffodils*, but there was no competition for the prizes offered for this flower. In the group staged *Emperor and Empress* were very fine, showing how admirably they are adapted for pot culture; whilst of older kinds, *ringlobus* and *Tenby* among trumpets, *poeticus ornatus*, *Burbidgei* and *Cynosure* of the star-flowered kinds made an effective group with *Anemone fulgens* as a margin. Messrs. Barr also sent a handsome lot of *Galanthus Elwesi* and its variety *marginatus*, which has very long stems and a fine flower. *Iris reticulata* and *Scilla bifolia* flowering in pots were also shown (silver Banksian medal). *Iris reticulata Krelagei* was shown in magnificent form and in quantity by Messrs. J. Veitch and Sons, the exhibit receiving a silver Banksian medal. This variety is very distinct in colour from the type and a gem among the early Irises. A group of miscellaneous plants from Messrs. J. Peed and Sons, Norwood, consisted mostly of greenhouse subjects such as *Cytisus*, *Erietas*, *Cinerarias*, and plants in flower of the fine white *Lilac Marie Legrave* and *Staphylea eoleiaca*. A silver Banksian medal was awarded. *Shortia galacifolia*, exhibited by Mr. Cornish, gardener to Lady Bowman, Jollywynds, Dorking, was given a cultural commendation, the specimen a magnificent one. Seedling blue *Primroses* were also shown. Messrs. Veitch sent a group of *Amaryllis* containing some noble kinds, besides those to which awards were made,

especially notable being *Elatior* and *Albrastus*, rich deep reds. A fine Violet named *Victoria* was shown by Mr. Jennings, Ascott Gardens, Leighton Buzzard; and Mr. G. Bolas, of Hopton Hall Gardens, Wirksworth, sent *Daffodils* effectively arranged among coloured Ivy leaves on a board for table decoration. Messrs. Paul and Son, Cheshunt, exhibited flowering plants in pots of the single *Rose Carmine Pillar*, which was figured in THE GARDEN, October 27, 1894. It is remarkably free-blooming, producing flowers from every bud along the shoots. The large-flowered variety of the Japanese *Rosa multiflora* (*Polyantha*) was also sent. A new break in the large-flowered race of *Cannas* was shown by the same exhibitors, the variety named *Dr. Masters* having yellow flowers, with a feathered band of red down the centre of the petals. Such varieties will hardly be as effective and distinct as the self-coloured kinds, of which several cut spikes were shown. A vase of large flowers of the common *Arum Lily* and a twin-flowered spathe came from Mr. Fitt, Panshanger Gardens, and cut flowers of *Strelitzia Reginae*, *Aristolochia Westlandi*, and *Rhododendron barbatum* were sent by Mr. Moore, Botanic Gardens, Glasnevin. *Boronia megastigma*, of which a good basket came from Mr. B. S. Williams, is a sweet, quaintly coloured greenhouse plant of the early spring. Its slender sprays are admirable for cutting, lasting fresh for a long time.

#### Fruit Committee.

A first-class certificate was awarded to—

**STRAWBERRY STEVENS' WONDER.**—This was remarkably fine for so early in the season, gathered fruit and also plants in fruit being shown. The plants in 6-inch pots carried from fifteen to twenty fruits in all stages. Some of the fruits, of a pale red colour, are conical, others wedge-shaped. The leaves are very small, similar to those of *V. H. de Thury*, but the fruit is quite distinct in colour and flavour and much larger. This Strawberry was much admired. From Mr. Stevens, Clayton Nursery, Hassocks.

Mr. G. Wythes sent from Syon Gardens St. John's Fig gathered from plants in small pots. This is a very useful variety for early forcing, as it bears freely and the fruit is of good flavour.

In the absence of the lecturer, the assistant secretary read Mr. Collenette's paper on the "Diseases of Tomatoes." In Guernsey no less than 1500 persons are employed in the production of Tomatoes, Grapes, and Melons. The Tomato crop was the most important and was grown in two ways, under glass with heat and without. The Tomato houses were mostly 120 yards long and 30 feet wide, and in many cases were not built in the best possible manner as regards favourable conditions to growth. The aspect was not always favourable, and the culture of the plants was carried out under difficulties. For instance, the soil was not nearly so good as in Jersey, the soil of Guernsey being a yellow clay and containing little plant food. In Guernsey many growers suffered losses of from £100 to £200 in Tomatoes alone in one season. The worst disease Guernsey growers had to contend with was what they termed the sleep disease, and the one most fatal to the plants. At first the plants present a dull appearance, then droop. After this there is a complete stoppage of growth, the fruits formed are allowed to ripen, and many growers reserve the best fruits for seed. This he considered most unwise, as the disease was propagated in this way. He had gone to much trouble to test the growth of plants from diseased parents. By using a strong microscope he had traced the germs of disease in the seed. He thought it most important not to save seed from such plants, as it was impossible for plants in any way attacked by bacteria to make free growth in their early stages. To prevent this disease he advised the use of pots, as the roots could be better managed in this way. A most troublesome pest was the eel-worm, which attacks the fibrous roots, producing root galls. The best

remedy he knew was an American one, viz., thoroughly freezing the soil before planting. In Guernsey this could not be done, but it could in England. They applied lime, sulphate of iron, and seaweed. Yellow blight is also very troublesome, but can be got rid of by keeping the plants drier with more air and withholding water. In the case of a disease called black stripe he advised the removal of all affected plants. This he considered a local disease. He strongly advised disease-resisting varieties, paying more attention to pure soil and thus keeping clear of minor diseases.

Mr. A. Dean thought Tomato plants were kept too much confined; more air was necessary and a humid atmosphere was harmful. Mr. Douglas said he never had disease in his Tomato houses. This he attributed to making the soil firm, never using any artificial manures, and at all times maintaining a dry atmosphere during growth.

#### THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE 29th annual meeting of this society was held on Monday last, Mr. Geo. Gordon (*Gardeners' Magazine*) in the chair. The meeting was well attended and great interest was evinced by the members in the proceedings. The report of the past year is of a most satisfactory character, encouraging both to the officers and every individual member. Seventy-two new members joined the society during the year, nineteen lapsed, and six died. Since the close of the year, however, there has been a most marked increase in members (*i.e.*, since January last). The membership now stands at 547. The sick pay has been more than in the previous year, £117 having been disbursed to twenty-eight members. Some of these have also received assistance from the benevolent and convalescent funds. Each of these funds is kept distinct and is worked independently. The amounts, as per ledger, due to each deceased member have been paid to their nominees. Subscriptions to the amount of £821 odd have been paid into the benefit fund during the past year exclusive of arrears. The benevolent fund has been increased by £59, the convalescent fund by £66, and the management by £58, irrespective in each instance of the arrears and of the interest of lapsed members to the management fund. The honorary members' subscriptions, including life members, amount to £65. Dividends on investments have produced £267. The entire receipts for the year—with the balance in hands of treasurer at the previous audit—amount to £1456, out of which £1000 has been invested in Corporation and other trustees' stocks for the sum of £1052, all these stocks being now at a premium. The total disbursements in sickness, in death and from the benevolent and convalescent funds—including also the management expenses—have been £267, which amount is itself covered by the interest of invested moneys as nearly as possible, leaving the balance in the hands of the treasurer. This result of the year's working cannot but be satisfactory, and it should result, as the executive trust it will do, in a considerable accession of members. Some gardeners with limited means are postponing the time of their decision in this matter, but surely they should seriously consider their position and interests, resolving if possible to join at once, and thus be able to provide for the rainy day in a more efficient manner. Young gardeners are particularly advised to become members, and thus in early life lay up a good deposit balance to their credit against sickness, infirmity, and old age. Mr. Gordon, as chairman, pointed out all of these benefits in the clearest and fullest manner possible, urging all the members present to do their utmost to get additions to the numbers at every opportunity. He also stated, after a thorough investigation of the books of the society, how well satisfied he was with the way in which the accounts were kept. He also instanced comparisons which had come under his own personal observation of

the benefits accruing to members of our large mixed societies as contrasted with those offered to members of the United, showing in a clear and effective manner the advantages that will accrue to a gardener who joins his own society.

The chairman at the close of the meeting was thanked most unanimously for his services, as were all the officers of the society. The special general meeting was then called, when Mr. Gordon again presided. This was to consider and sanction the increase of sick pay from 10s. to 12s. on the lower scale and from 16s. to 18s. on the higher scale without any additional sum being paid in contributions by the members. It was resolved that these additional benefits be given subject to the sanction of the Registrar of Friendly Societies, to whom the matter must now be referred. The proposal to make this increase was made by the treasurer after the matter had been fully discussed in committee at several meetings during the past year. This increase should be an additional inducement to those who still remain outside the benefits of the society for them to join at once and thus reap the benefits offered.

#### MR. SAMUEL PARSONS ON BEDDING PLANTS.

MR. SAMUEL PARSONS, JUNIOR, has an interesting article in *Scribner's* on this subject, which deserves attention for the good sense that is in it as well as certain other things which deserve a few words. He defends the system, but the illustrations of his paper do not show a trace of true bedding-out, the beds and masses being bold, varied and graceful, and much aided by the picturesque effect of plants in water in Union Square. In water, plants taking to a great extent their own shape and disposition give us a beautiful effect. Mr. Parsons calls bedding the "poor man's system," and says the plants cost but a few pence each; but that is not the case. The beautiful "poor man's garden" here is generally a garden in which the plants cost nothing, however beautiful many of them are. But to say that a system of the plants which he confesses die absolutely every autumn is a "poor man's system" is surely straining a point. When we come to arrange any flowers in artistic ways there is an end to the question. Mr. Parsons does not take note of the fact that at first it was not a question of the Palms or elegant Cannas, but of hard lines and flowers, which one has not very far to travel to see yet in England. In America, owing to the fine summer heat, fine-leaved plants acquire great freedom of growth, which helps the gardener very much; but, after all is said and done, and assuming that plants treated artistically are all of the same value, how about the stock dying in the autumn? Is it not possible in such a climate to have a great number of things that do not perish in the autumn while keeping on to the best of the flowers that live a summer only? It certainly is in our country. It is all very well to talk of putting out half a million of bedding plants, but we should like to see these supported by several millions of plants that may be allowed to remain a few years in possession of their holdings, and so lessen a bit the dreadful and ugly labour of planting the garden when it should be in all the early flush of its summer beauty. Mr. Parsons

does not say a word about the wonderful results of bedding out obtained in the great western cities, such as Chicago, of which we see such unpleasant evidence in some American gardening papers; and not a word of the Italian pastrycook who became a distinguished gardener in Chicago and carried out in bedding his latest ideas of pastry. The real article flourishes in Chicago—at least we have this evidence in Mr. Falconer's paper and in others. We should like to hear what the superintendent of the Central Park thinks of the figure of the globe in carpet bedding built up in the centre of scaffolding and wirework to get a hold for the wretched plants doomed to such degradation.

#### NOTES OF THE WEEK.

**Allium neapolitanum** and **Anemone fulgens** make an effective group in the greenhouse at Kew and show the value of hardy things grown in this way and brought into flower in advance of those outside. They are more beautiful by far than many of the ordinary occupants of greenhouses.

**Rose Duke of York.**—This, one of the latest additions to the sweet, ever-blooming class of Monthly Roses, was well shown on Tuesday by Messrs. W. Paul and Son. Plants in pots were bearing many flowers, which, although produced at this sunless time, showed much of the characteristic variation in colour peculiar to the kind.

**Snowdrop Cassaba.**—This will no doubt become a very popular Snowdrop in gardens. At Kew it is classed as a variety of *Elwesi*, but it is very distinct in many ways, the fine large flowers having stems of considerable length and of a decidedly pale yellow colour. The leaves, too, are long and broad. Established groups in their second year show marked improvement as compared with newly-collected bulbs.

**Shortia galacifolia.**—The very fine specimen of this exhibited at the Drill Hall on Tuesday by Mr. Cornish, gardener to Lady Bowman, Jollywinds, Dorking, attracted some attention. The plant, growing in a wide shallow pot, was very luxuriant and profusely flowered. It had about forty spikes of bloom, many of them being twin-flowered. In leafage as well this is a beautiful plant. A coloured plate of it appeared in *THE GARDEN* of August 30, 1890.

**Phillyrea Vilmoriniana.**—This handsome shrub is one of the few evergreens that have passed through the recent severe winter without being damaged. It has stood 22 of frost at Exeter without showing the least sign of the continuous severe weather. The large deep green leaves look as fresh as they did at midsummer, while all around them the wholesale slaughter wrought among other so-called hardy shrubs is only too painfully evident.—M.

**Pentapterygium (Vaccinium) serpens.**—This Himalayan plant is now flowering at Kew. Its shoots, which are several feet in length, rise from a thick fleshy rootstock, and break into several branches at their tips. They are like those of the *Pernettya*, but the main stem is leafless. The flowers, however, are produced in great profusion down to nearly the base of the plant. They hang singly and in pairs from under the shoots, producing a graceful and brilliant effect; the colour a bright coral-red.

**Snowdrops at Kew.**—These are very pretty now flowering in the Grass, as at Kew. This way of adorning large areas of turf with the earliest of spring bulbs will give our public parks and gardens a new interest, and add greatly to the delight of those who visit them. With bulbs so cheap there is every inducement to plant them liberally, and even if they have to be renewed at

times, the gain in beauty is immense. The beauty of the flowers springing out of the fresh turf is preserved to the end.

**Olearia Haasti as a seaside shrub.**—Many of your readers have spoken well of this deservedly popular shrub. The severe winter did not affect it in the least, and over 20 of frost have not altered its appearance. At Penzance, where a few months ago furious gales raged with such violence that a portion of the esplanade was washed away, and the salt spray from Mount's Bay was carried over the house-tops and deluged the gardens, *Olearia Haasti* was one of the few shrubs that withstood the salt spray, and can therefore be highly recommended as a seaside plant.—M.

**Primula verticillata.**—It is a pity that this lovely *Primula* is not hardy outdoors, but as a greenhouse plant it is decidedly pretty, coming into flower early and lasting a considerable time. There are some groups of it now in bloom in the greenhouse at Kew. The pots each contain three plants. Single plants in pots of the same size will grow larger in leaf and throw up stout spikes of bloom. Seedling plants with single crowns and one flower-spike are always the best, and if the pots they grow in are stood in pans and watered from them there is no soiling of the leaves, which add so much to the beauty of the plant. The flowers are very numerous, of a clear yellow colour, disposed gracefully in whorls. They are also sweet-scented.

**The Charles Collins fund.**—The executive beg leave to tender their sincere thanks to those who have so generously responded to their appeal for subscriptions to the above fund, and to say that they propose to close the latter on Wednesday, March 20, after which immediate steps will be taken to decide as to the most appropriate manner of administering the same for the benefit of the widow and children. In the meantime they would feel exceedingly obliged if those who kindly promised to contribute to the fund would be good enough to remit the amount of their subscription to the honorary treasurer, Mr. George Gordon, Endsleigh, Priory Park, Kew, or to the undersigned, on or before March 20, in order that the fund may be finally closed by that date. The total amount received or promised up to date is £62 19s. J. W. Sanders, honorary secretary, 57, Cressingham Road, Lewisham.

**Cœlogyne at Minchinhampton.**—I do not think that amongst the many species of *Oreohids* which are and will be in flower from now onward till well into the early summer months there are any which can surpass *Cœlogyne cristata* and its varieties; certainly there are few which can equal them as decorative plants. Mr. Wilkinson, the gardener at Highlands, has for many years been noted for the fine specimens he grows. This year they are exceptionally good. I had the pleasure of seeing them the other day when in the neighbourhood. They were arranged on one side of an intermediate *Oreohid* house and presented a sheet of snowy white. Amongst them were fine specimens of the Chatsworth variety (true) *Lemoniana*, a magnificent specimen, but not quite out, and a distinct form with broad foliage, the flowers large, pure white, with a soft yellow throat and very broad petals. This plant is said to be distinct from the Chatsworth variety and much better. When in the bud state the outside of the flower is quite white, while that of *Lemoniana*, *cristata*, &c., is brown.—T. A.

**Phaius Blumei var. Bernaysi.**—This is an *Oreohid* of exceptional interest and rarity, and it is now represented by a fine plant bearing two flower-spikes in the *Oreohid* house at Kew. In habit, foliage and structure of flower it has a close affinity with the well-known *P. grandifolius*. Indeed, *P. Blumei* as well as *P. Walliichi* and *P. bicolor* are by some authorities looked upon as forms of *P. grandifolius*. In colour of flower, however, no *Oreohid* in this group has much resemblance to this variety *Bernaysi*, the entire flower being of a soft, beautiful shade of creamy yellow in front, with the exception of the apex of the lip, which, like the back of the sepals and petals, is

almost pure white. The flower-spikes are 3 feet high, backed by leaves as large as those of *P. grandifolius*. It is, in my opinion, the most beautiful of this section of *Phaius*, which in a wild state is spread largely over the far East. *P. Blumei* itself is found in Java, but the variety under notice belongs to the Australasian region. The particular plant at Kew came from Fiji, but it has previously been collected in Queensland. It is named in honour of Mr. Bernays, a promoter of the Acclimatisation Society of that colony.—B.

**Glass insurance against hail.**—The Nurserymen, Market Gardeners, and Hailstorm Insurance Corporation, Ltd., have issued their prospectus. The corporation came into existence on February 27 with a capital of £100,000. The main feature of the corporation is that it will be carried on for the mutual benefit of the trade, the surplus profits being returned to the shareholders by way of dividend. It seems a very useful corporation with distinct aims, and it has the support of some of the men most practically interested in the trade. It is a very good idea, and no doubt will succeed. The chairman of the corporation is Mr. Harry J. Veitch, and the list of names of directors comprises some of the principal members of the trade. Mr. Alexander James Monro is the general manager and secretary *pro tem.*, and the corporation has registered offices at 1 and 2, King Street, Covent Garden, W.C.

**Notospartium Carmichaeliae.**—Some time ago this beautiful pink Broom of New Zealand was illustrated in THE GARDEN from a photograph sent by Messrs. Veitch, of Exeter, in whose grounds it had bloomed abundantly. The present severe winter has brought to light the curious fact that this New Zealand species (of whose hardiness great doubts were entertained at first) is really hardier than our common native Broom (*Cytisus scoparius*). Two handsome specimens of the pink Broom planted in Exeter do not show the slightest trace of the exceptionally severe frost, while the shoots of the common Broom are perfectly black, and many Laurels, *Laurustinus*, *Euonymus*, and other shrubs generally considered perfectly hardy are nipped so severely, that in some instances not a single green leaf is visible. This certainly proves the hardiness of *Notospartium Carmichaeliae*, which no doubt will soon become popular.—F. W. M.

—The pink Broom of New Zealand is evidently very hardy. It is quite untouched by a frost that has blackened the common Broom and cut the Furze down to the ground. It is a graceful and pretty thing as yet not very well known, but the fact that it is so hardy is a great point in its favour.—STUSSER.

**Strawberry Stevens' Wonder.**—At the Clayton nurseries, Hassocks, Mr. J. Stevens is growing this largely. It was shown at the R.H.S. on Tuesday, and given a first-class certificate. There is now to be seen a batch of 4000 plants in flower and fruit, the majority of them in the latter state, and therefore affording ample evidence of its worth. Whatever may be the ultimate result of testing it in the open air beside the best kinds now grown, there can be no doubt as to its value for forcing. The long double rows of plants on shelves extending the whole length of the houses, with heavy clusters of ripe fruit hanging over the edges of the pots, showed its value. There was scarcely a bad plant to be seen throughout the entire batch. This Strawberry has now been grown by Mr. Stevens for about seven years, the stock having been raised from one plant given to him by a friend, who told him it was a seedling. At first, whilst this kind was scarce, he grew *La Grosse Sucrée* as well in pots, but observing the marked superiority of the seedling plant in free setting and early ripening, the older sort was discarded. A striking characteristic of this new kind is the short-stalked, tufted, compact growth of the leafage, a most desirable thing in a pot Strawberry. It fruits freely and sets well. Upon one truss sixteen fruits were counted all swelling away. A number of fruits weighing 1½ ozs. each

had been already gathered and fruits of 1½ ozs. each were abundant. The colour of the fruit is a light red and the flesh is remarkably firm and solid, so that the fruits travel well. The flavour, too, was good, especially taking into consideration the sunless time that has prevailed. The first fruits were gathered on February 6, and up to the time of my visit (March 2) over 90 lbs. of marketable fruit had been gathered. Another distinctive feature of the kind was a decided tendency to successional blooming even upon plants that were then carrying a heavy crop of ripe and ripening fruit. Fully sixty per cent. of those in fruit were sending up trusses of flowers which doubtless will give a second crop sufficient in quantity to repay the attention necessary to bring it to perfection.—A. H.

**The weather in West Herts.**—The temperatures have been variable, but on the whole there has been a gradual rise in temperature since the beginning of the month. On two days during the past week the highest shade temperature was about 50°, and on the 11th inst. it rose to 52°. On no night did the exposed thermometer show more than 10° of frost. At 1 foot deep the temperature of the ground stood at about the freezing point until the 3rd inst., but since then it has risen 7°. It now stands at 39°, or a degree colder than the March average for the previous nine years, and 4° colder than on the same date last year. Rain or snow has fallen on eight days this month, but to the total depth of only about half an inch. A selected bush of the wild Hazel first opened one of its fertile flowers on the 12th inst., which is a month later than its average date for the previous four years. *Crocus Imperati* first flowered in my garden on the 11th inst., or fifty-one days later than in 1894.—E. M., *Berkhamsted*.

—W. BATCHELOR.

**Flowers from the Scilly Islands.**—About 4½ tons of Scilly flowers were despatched from Penzance lately for the London and midland markets. This is only about a quarter of the quantity which was being sent about the same time last year.—*Western Morning News*.

**Stocks for Vines.**—Will any reader of THE GARDEN inform me what is the best stock to graft the following Vines on: Muscat Hamburgh, Madresfield Court, Gros Colman, and Gros Guillaume? Though much has been written about this question, I am not quite sure which is the best stock for each kind.—R. KATZER.

**Erratum** ("Supporting Hyacinth Spikes," p. 158).—For "wire gauze" read "a wire gauge."

**Names of plants.**—*Mrs. Towler*.—*Usnea barbata*.—*W. Andrews*.—2, *Acacia longifolia*; 3, *Acacia falcata*.—*E. S. S.*—1, 2, 3, all ordinary forms of *Dendrobium Wardianum*; 4, ordinary form of *Cœlogyne cristata*; 5, *Dendrobium nobile*.—*James Davidson*.—*Masdevallia tridactylites*.

**The Wild Garden:** or, the Naturalisation and Natural Grouping of Hardy Exotic Plants, with a chapter on the Garden of British Wild Flowers. Fourth edition, with wood engravings from drawings by Alfred Parsons revised and enlarged. Teny 8vo, linen cloth. Price 12s.; well bound in half morocco, 15s. Through all book-sellers.

No. 1218. SATURDAY, March 23, 1895. Vol. XLVII

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ORCHARD AND FRUIT GARDEN.

## GRAPES FAILING TO SET.

WE frequently see instructions how to treat Vines in flower to ensure a good set, and correct temperatures are given for the Vines during such a critical period. Although such advice is followed out, we sometimes fail to see even a moderately good set, and the grower is puzzled to account for his non-success, as he is perfectly sure that his methods have been correct, as proved by his own past experience and also by the writings of other practical men. There can be no question the instructions given are reliable, but there are local causes that are apt to upset the most skilful efforts to secure a good set, and which are accountable in a great measure for the failure. If the roots are in an unhealthy state or beyond the control of the cultivator, the difficulty becomes greater, and no skill on the grower's part can ensure a perfect set. The only remedy is to wait until autumn and to then bring the roots near the surface in a new border. On some soils Vine roots may travel at will for almost any distance without any bad results, but such soils are somewhat rare. Another cause of a bad set is mistaken kindness on the grower's part. With a very laudable desire to produce Grapes of extraordinary merit, he gives strong applications of manure in a liquid or solid form (it may, perhaps, be natural or chemical manure, or both together) just prior to the bunches coming into flower, thinking that he will assist the Vines by a heavy dose of plant food to set the crop well. No greater mistake could be made with manures at that season, particularly if the borders are inclined to be heavy, as immediately previous to the bunches coming into bloom the new roots just formed are very sensitive, and strong applications of plant food are very liable to burn or injure the points or feeding ends of the roots, thus defeating the aim of the grower, as an imperfect set is practically certain. Another factor that is not always recognised is dry places in the border. It may be that the soil near the hot-water pipes is dry for a considerable depth, in spite of apparent moistness through syringing or damping down, but it stands to reason that the continual heat from the pipes causes a greater evaporation than what takes place further away. Inequalities on the surface of the border also will cause some spots to be much drier than others; consequently, root-action is not so healthy and free as it should be. It will perhaps be said that if a thorough soaking is given when watering, the whole border would be moistened uniformly by gravitation, no matter how uneven the surface was; but actual experience has proved the contrary. On several occasions I have had to assist in or make alterations in Vine and other borders under glass, and have found some parts as dry as dust and others very wet in the same border, although no difference could be detected on the surface. In such instances it has been astonishing that any Grapes ever set at all. If moles or rats get burrowing in the borders, channels are made by them, through which the water runs, leaving portions of the soil perfectly dry; not only so, but they will eat roots through that are in their way and inflict injury on the Vines, causing a bad set,

weakness, or inferior Grapes. I had a strong proof of this in our Black Alicante house three years ago, as the moles got into one end when the Vines had made a few inches of growth. The end Vine in particular indicated distress by growth ceasing and the leaves flagging by sun heat, and before all the moles could be caught sufficient damage had been done to produce a poor set and smaller leaves than on other Vines the roots of which had not been injured.

With the roots near the surface and in a thoroughly healthy condition, and cultural details correctly carried out, temperature has not so much power to ensure a perfect set as often stated, or rather it is unnecessary to take so much pains to maintain it above a fixed point. As an instance of that I may mention that one year, through no fault, I could not keep a night temperature of more than 45° in the Muscat house all the time the Vines were in bloom. The days were certainly bright and favourable, yet in spite of the fall in temperature at night I had the best set Muscats I ever had, most of the berries having four stones and each bunch required liberal thinning. At the same time I do not advise a low temperature, rather the reverse; the object is to have the roots in the right state, for on that hinges success.

W. G. C.

**Colour in Apples.**—Generally we do not expect to see much colour upon fruit of Wellington. I lately saw some fruits gathered from trees in Mr. Perkins' garden at Portswood, Southampton, which were, I may say, most brilliantly coloured, reminding one almost of Worcester Pearmain, so bright was the skin. From the gardener, Mr. Miles, I learnt that many trees of this Apple are growing in standard form on grass and all succeed capitally. Mr. Miles has been experimenting upon several of the trees with a view to increasing the colour of the fruit. Judging from the specimens inspected, he has succeeded in a remarkable degree. Fruit from trees of the same variety not treated in the same manner is pale or of the usual colour, which to me is an absolute proof that the colouring of Apples is influenced by the constituent portions of the soil in which the roots subsist. At the same time I do not infer that the soil is wholly the cause of such deep colouring as may be obtained. In the present instance, as in all others where good or highly coloured Apples are obtained, the fruit is not hidden by foliage caused by a thicket of branches. The trees in question are twenty-six years old, trained and managed at the present time as freely-grown standards, but not closely pruned. Sulphate of iron and soot are the chemical agents employed with such satisfactory results. The sulphate of iron was sprinkled upon the grass which is growing underneath the trees freely during showery weather when the fruit was about half its full size. Soot is scattered over the surface several times during the year in the same manner. To the influence of soot upon the roots of the trees Mr. Miles attaches much importance as a colouring agent, and, from the specimens seen of the Apple in question, with very good reason. Although the Wellington succeeds so well in certain parts, it is an utter failure in others. Here in our cold soil a standard tree has not given a satisfactory crop since it was planted fifteen years since, although it has grown well.—E. M., *Bishop's Waltham.*

**Rivers' Early Nectarine.**—I was pleased to see the note at page 111 on this new fruit and trust that we have secured a Nectarine some three or four weeks in advance of Lord Napier, as described by "Wiltshire Gardener." In a month or two this fruit will be proved, as doubtless many fruit growers have their new stock in fruiting condition this year. Those who force can see at a glance how far the growth is in advance of Lord Napier. I have the tree only on open walls. So many very fine fruits have come from Messrs. Rivers, that Rivers' Early Nectarine is likely to

be a special favourite for many years to come, and will prove a rival to the well-known Lord Napier, one of the best all-round Nectarines we have, good both in the forcing house and on walls in the open; but that is of little consequence, as if it be superior to that variety a great point is gained—there will be less hard forcing and equally good results. The grower quoted above describes the new variety as a large flowered one and somewhat similar to Lord Napier, requiring care in setting; and I am of his opinion—that the large-flowered varieties are not such free setters, whether Peaches or Nectarines. So far I have never found the least difficulty in setting Lord Napier, but the reverse, as it sets too freely. I expect when the new variety attains the same strength as the older kind it will be equally free setting. With me Lord Napier sets much better than Elruge and is, I consider, superior in every way. Elruge, though it sets enough for a crop, does not set so freely as the variety named. With many new fruits a fair test cannot be expected the first season, as the trees must get well established. There is such a demand for stock that time must be allowed for the trees to make sufficient strength to mature the fruits. Early flowering, I may remark, does not signify early ripening.—W. M.

**Peach and Nectarine trees dropping their blossom-buds.**—This is a perennial complaint made by both amateurs and gardeners, and both are slow to admit that they have themselves to blame for it. Out of doors blossom-buds and blossoms are frequently so damaged by frosts that they will drop off, let the gardener do his best. Skilful and persistent attention is of no avail; nothing can stand against continued cold winds, with the temperature below the freezing point. Under glass and the houses well constructed, the buds should not drop before the blossoms are developed nor after the blossoms decay even when early forcing is necessary. The causes are as follows: Imperfectly developed and badly ripened wood, owing to the premature destruction of the leaves by red spider, aphid, or mildew, aggravated by lack of heat after the fruit is gathered. Peach and Nectarine trees want attention until the leaves drop naturally. Another frequent source of this evil is over-dry borders in winter. Vine borders may be allowed to become almost dust-dry in winter (although they ought not) without any apparent evil resulting therefrom. Not so Peach borders. The roots of Vines are apparently dormant in winter, but the roots of Peach and Nectarine trees are always in an active condition. The roots are always pushing into the border, and if the soil where the points of the roots are becomes dust-dry, the extremely delicate cells at the growing points of the roots are injured and destroyed by thousands, and when required to act are incapable of action. The flower-buds develop rapidly in the atmosphere of the forcing house and drop off owing to want of support. These are the principal reasons. It is not difficult to apply the remedy.—J. DOUGLAS.

**Apple Loddington Seedling.**—I agree with all that "S. H." writes in favour of this old favourite on page 111, as it is one of the most prolific varieties that I know and succeeds admirably on all and every form of tree. As the grafting season is upon us again no mistake can be made in sawing off the heads of young and unfruitful trees, grafting again with a variety that is large, of good appearance and a continuous bearer. Of late years some attention has been drawn to cordon trees trained by the sides of the walks about 15 inches or 18 inches from the soil. The number of varieties that are a success on that system of training are very limited, but Loddington can claim to be one of that limited number, never failing to crop.—W. G. C.

**Apple Cox's Orange Pippin.**—"E. M." is fortunate in getting this superb Apple to crop freely with him. Here in Herefordshire it is a partial success, in some places doing fairly well and in others only a mile or two away refusing to

fruit at all. I have a considerable number of dwarf and other forms of trees of this variety. Dwarf trees do very well, but standards every year are infested with mildew and cannot be said to be profitable; but as "E. M." remarks, where this Apple does succeed well it ought to be planted very extensively. No Apple that I have grown is so much in demand, which always exceeds the supply. I think I have tasted Apples from every clime in which they grow, but never found any to equal a good English-grown Cox's Orange Pippin.—W. G. C.

#### AMERICAN PEACHES.

THE remarks of "W. L." on the varieties of American Peaches are worthy of special attention by Peach growers, and I think all who have tried them over a series of years will feel disappointed with them for forcing. When Early Alexander and Waterloo first came out, I planted them for furnishing ripe Peaches in May, and for a few years they did remarkably well, casting comparatively few buds, and ripening up good crops of handsome fruit that looked very tempting, but was not so good in flavour as appearances represented them to be. However, after the lapse of a few years, bud-dropping became general on all the American varieties, while European sorts in the same house did not cast a bud, producing excellent crops annually. This year I have rooted out most of the former, and shall be very shy at again trying American varieties. There are hosts of causes mentioned from time to time as to what produces such a serious defect as bud-dropping at the time of starting Peach trees, but in the varieties under notice I feel certain the defect is constitutional in our climate, or rather under our conditions of forcing. Although American Peaches succeed very well on walls outside, they will not last long in a healthy and fruitful condition when forced, according to my experience and observations in other gardens. It may be possible that forced trees will not repeatedly stand the long season which frequently lasts from November to end of September, or say only two months' real rest, as many gardeners commence to force at the end of November, and if the trees are healthy and free from insect foes, they rarely lose their foliage before the end of September. I believe no trees are at rest until all leaves are down; in fact I question if root action ceases until a later date. Many, if not all our English Peaches will stand this long season of growth or activity with a short period of rest for years, and I think "W. L." has done a great service in drawing attention to the serious failings of American sorts, and he will also have saved some intending planters a loss and disappointment, as, after reading his excellent and timely observations on young Peach trees, they will in all probability not choose the unreliable American varieties. W. G. C.

**Pruning Peaches.**—This work should now be brought to a close. In favourable seasons it would have been completed before this, but with an arctic winter much work among hardy fruits has been at a standstill. There is a great advantage in such seasons as that we have just passed through in paying ample attention to summer stopping, as by so doing there is little pruning of any kind—merely removal of naked branches and giving the young or stronger wood space to develop. The trees are later this season than I have known them for years, and I should say there is every prospect of a good crop, as though the autumn was not favourable to ripening the wood, where attention was paid to the removal of old fruiting wood and useless shoots the new wood presents a brown and firm appearance. After pruning, I leave my trees unnailed as long as possible, and tie the young fruiting wood out so as to get as much exposure as possible. Once the flowers show colour, it is not wise to delay the nailing, at the same time giving the necessary protection to the flowers. If planting of any kind has been done since the break up of the late frost,

nailing should be left as late as possible, and the surface soil well firmed by treading previous to nailing. The surface soil of recently-planted trees will be best left in a rough state for a time, as such trees will require time to settle. Covering with a mulch at planting will cause the surface soil to be much colder than the surrounding soil. Ample mulchings later on will be beneficial and check drought. To dry, light soils these remarks do not apply as when there is a heavy clay soil to deal with. In the case of light soils watering may be necessary soon after planting, as the recently dug ground will dry quickly at this season. When renailing, it is best to remove all old shreds, which harbour insect pests. Give young shoots ample room to swell, as if the wood is tightly pressed, it is the cause of gumming and canker. In tying large branches with twine allow room for expansion, and in securing the main branches of young trees take care not to crowd at the start, so as to leave room for young wood.—S. H. B.

**American blight.**—This pest is often left unnoticed at this season, with the result that it is rampant in July, August and September. Growth being late this year there is still time to cope with the disease. Cordon, bush and pyramid Apple trees are more liable to American blight than others, as it spreads so readily, the manner of growth to a certain extent assisting in its development. I find that soluble petroleum and clay mixed to the consistency of paint and well rubbed into the crevices of the trees attacked by blight will do much good. I have also used a brush dipped in the paraffin, but do not advise it for young trees, as the spirit is soon exhausted, whereas the paint remains good for some time and the tender bark is not injured. I am aware painting is a tedious process, but if not attended to there is total loss of trees, as by syringing in the summer one cannot reach all parts of the trees.—G.

#### THE GLASTONBURY PEAR.

THE Glastonbury Pear and the Benedictine are the same. Mr. Carter's inquiry recalls to me what took place in the early sixties. The first public notice of the Glastonbury Pear was taken by the late Mr. Shirley Hibberd, who was one of the judges at the mid-Somerset Horticultural Society. At his request I sent him some fruit which Dr. Hogg, I believe, exhibited at the R.H.S. meeting. I was requested to give its history, which appeared in the *Journal of Horticulture*. At that time there was standing an old stunted Pear tree in a hedge at the back of St. John's Church; it was looked upon as a wilding. The fruit was small and indifferent, but of fine flavour. It would have remained unknown had not Mr. Chapman taken grafts or scions from the old tree and grafted them on fresh stocks. I was then making a collection of Pears and considered that particular Pear out and out the best, Doyenné du Comice then not being known. I considered that through the trade something profitable might be made of it. Accordingly, I grew a great many trees for grafts or scions, many of which I gave away to applicants in this country and America, amongst them the late Mr. T. Rivers and John Scott, of Merriott. Some few years after I left my home and the Pear trees. During that time some one in the trade played a trick on the trade and public and had my grafts, which gave me much annoyance, as I had heard from Messrs. Rivers and Scott that they had bought maiden trees of a Pear which had been shown at the R.H.S. and certificated and named Benedictine, a seedling raised at Glastonbury; parentage, Huyshe's Prince Albert, I think, and an old kind growing in the abbey enclosure, and called after the order to which the monastery belonged. Both Messrs. Rivers and Scott immediately recognised the similarity of growth, &c., in the old and new shoots, and resented the imposition.

I have again turned my attention to fruit growing, being again settled at home. A few years ago I sent some of the fruit to Mr. Iggulden,

who considered them first-class; the misfortune is it is of the same season as Doyenné du Comice. At the same time I sent some to Mr. G. Bunyard and give you an extract from his letter. November 11, 1890: "The two Pears are large in size and of the finest quality. We should like some grafts, as Pears that bear in such a bad year as this are worth propagation. We shall be pleased to send you trees or grafts in exchange." I have come to the conclusion the sort has its likes and dislikes of soil, situation, &c., and cannot be relied upon as Doyenné du Comice year after year to be first-class. This last season especially with me proves it. It is a certain cropper; for the past thirty years a tree horizontally trained on a S.W. wall has never failed. Fruit thus grown will average 10 ozs. to 12 ozs., and some over. Shape bluntly pyriform, skin peculiarly thin, cinnamon-brown colour, deep rufous-brown suffusion when exposed to the sun. It is at its best in the first fortnight in November; texture slightly gritty, according to the season. It is a juicy luscious Pear with a peculiar subacid flavour. J. A. POWELL.

**Apple Newton Wonder**—Sent out a few years since as a late keeping variety, this Apple is sustaining its reputation and deserves to be more extensively planted, as its constitution appears suited to various kinds of soil. In shape the fruit is not unlike that of Belle Pontoise, though rather more conical.—E. M.

**Grafting fruit trees.**—Preparations must now be made for grafting, and as it often occurs there are varieties one may wish to grow and to get fruit of in quantity in a short time, grafting is the quickest way to secure a crop or to obtain better varieties on old trees. Large regrafted trees may be had in a bearing condition in three or four years. Grafts for inserting later on should now be got ready for the work. These should be cut at once and healed in a shady cool corner. Stocks should now be headed down, as at this date there is no fear of dying or shrinkage of the bark at the portion cut back. In the case of large or old trees it is not necessary to cut back so severely as is frequently practised. It is an easy matter to insert a large number of grafts if the trees are not cut too low and a quick growth is secured with a better balanced head. In selecting grafts be careful to obtain them from clean trees.

**Protecting wall trees.**—Apricots will claim first attention. So much depends upon the situation or position of the trees, that a hard-and-fast line cannot be observed. In my case I have wide copings and, of course, less protection is necessary. Glass copings are most desirable and of great utility where they can be fixed and readily removed. Permanent copings I do not advise, as during the greater part of the year the trees are best exposed. With a permanent coping it is a difficult matter to keep the foliage clear of red spider. When the trees are given a warm covering like frigi domo I would advise care in its removal in mild weather, as a close, sunless atmosphere will bring the blooms down in shoals. The bloom of many fruit trees, if in a dry state, will stand severe frosts; hence the value of a good coping to throw off rains and keep the flowers dry. Many growers use double or trebled fish-nets, hung loosely over the trees, with a few supports to keep them clear of the wall. Scrim canvas or tiffany is also a good protector, as, being light, it does not prevent air passing freely to the trees. When a good protector is obliged to be put up merely for bloom protection, it must be borne in mind the best results are often secured by the most primitive means. I have previously noted the importance of air passing to the trees, as too heavy coverings weaken the bloom, and it would be better in such cases not to cover at all. Whatever means is adopted to protect the bloom it is not necessary for the covering to reach the bottom of the trees. Curtains made with rings to run on iron rods are more readily placed in position than any other movable protection, but even then I would advise a thin material for the curtains, drawing them aside early in the day, and in mild weather letting the trees be freely exposed.—W.

## BULWICK.

THE artistic garden, notwithstanding much talk of gardening in these days, is one of the rarest things to find—as rare as the great book or the true picture. Rambling about Northamptonshire last autumn, and delighted with its beautiful old houses, many of them, unfortunately, as bare of flower gardening as a deserted ship, it was pleasant to come to a real garden at Bulwick full of Carnations and many open-air flowers arranged in various pretty ways, even the house being full of large basins of Carnations, some of them of one self-coloured kind—a rare pleasure.

The flower garden was not one of those places which astonish us by a showy display, but modest at first sight as regards flower

kitchen garden thrown into 4-foot beds, with little beaten alleys between, in which many thousand Carnations were grown in simple masses, almost as they would in the nursery.

One sees at once how much more beauty and variety can be got in such ways than where all the effort goes to help one scheme for effect in front of one's windows. Some kinds of Carnations were grown very finely, and the finest single bed of one kind of Carnation I ever saw (Ketton Rose) was here with many thousand fresh buds and blossoms—a wondrous sight, which the engraving attempts to show.

What is the secret of beauty in such a garden, and what the lesson to be learnt from it? It is that no one way will give

found the secret we cannot always pursue the same plan, though we may learn much. It would be better for our flower gardens if imitation were more difficult, as the greatest pleasure of the garden only comes when the best use is made of every scrap of the ground and with plants and ways adapted to the spot and to no other. The late Lady Henry Grosvenor was not only a lover of good gardening, but a real gardener herself, and she was well supported by her excellent gardener, Mr. Drantfield.

I have to thank Miss Willmott, who knew the garden well, for an excellent series of photographs of the garden at Bulwick, some of which have been engraved for THE GARDEN and are issued in this number.—W. R.

A correspondent sends us the following details of the garden in 1894:—

Bulwick Park, Wansford, lately occupied by Lord and Lady Henry Grosvenor, is a very old mansion situated on the southern slope of a valley in the midst of some very fine wooded scenery in the county of Northamptonshire. The house, built about the year 1602, is entered by a pretty colonnade, which borders one side of the garden, and has a very nice effect. From the mansion to the flower garden is a grey stone flag path about 12 feet wide, on which stand during the summer months large tubs of *Agapanthus umbellatus* and grey stone vases filled with scarlet *Geraniums*. The flower garden is flanked on both sides by a shrubbery with a margin left in front for herbaceous plants, &c., amongst which are conspicuous the *Inulas* and *Giant Hemlock* (*Heracleum*), growing 12 feet high. In the centre (looking from the steps) of the garden is a broad sweep of Grass. On either side, running the whole length of the garden, are two long borders filled almost entirely with herbaceous plants; noticeable in particular are the perennial *Sunflowers*, *Delphiniums*, *Gypsophilas*, *Asters*, *Anthemis tinctoria* and its white form, tufted *Pansies*, and a great many *Narcissi* and early-flowering bulbs, each coming into flower in its own season and forming a very pleasing contrast to the massed beds of *Geraniums*, &c.

The garden could easily be divided into two, and each would form a complete garden in itself, but in planting them the idea has been to make the whole one complete harmonious arrangement. Four of the corner beds are planted with *Clematis Jackmanni*; the other beds that balance these are planted with white *East Lothian Stock* and tuberous *Begonias*, the latter on a groundwork of golden *Thyme*. This makes a very pleasing effect. The four half-moon shaped beds round the centre of the garden are planted with *Geraniums*, each bed being filled with a distinct coloured kind. Down the centre of each side of the garden at equal distances are three large round raised beds; the smallest in the centre of the three is filled with *Sweet Lavender*, coming through it is *Hyacinthus candicans*. The first round beds, looking from the steps, also the farthest (which is the largest), are filled with mixed plants, the idea being for yellow and purple to predominate in the two farthest beds. This is effected by using *Anthemis tinctoria*, *Delphiniums* and *Campanulas* interspersed with *Dactylis glomerata variegata*, *Zea*, and the *Giant Flax*. Round the outside is a row of grey *Lavender Cotton*; outside this again is a row of purple *Chilian Beet* (these large beds are about 30 feet through).

The other two large beds (near the slope) are filled with mixed plants; conspicuous among

Covered way, Bulwick.

gardening in immediate relation to the house. That, however, was interesting, and had more leaf and grace about it than are usual.

The chief charm of the place was not there, however, but rather in various little side gardens and long and pretty borders backed with Holly and other hedges, and giving an opportunity for growing a great number of hardy flowers which bloom in the autumn. These formed picture vistas, of which the effect is very often better than a flower garden of the usual type.

But, more than this, the excellent plan was followed here by the late Lady Henry Grosvenor of having what I do not think any garden can be rich and satisfactory without, namely, a "square" or reserve garden in which things are grown well without reference to effect. It was a large square of the

us a true garden which is likely to be beautiful even for any length of time even in the fine season. Any one way is so liable to failure from the weather or other causes, that the main source of success is to have a good many ways with flowers, as there were at Bulwick. Hardy plants in beds and borders apart from the flower garden proper (that, too, being pretty) are the source of the charms of this garden—the variety of situation, variety of plants—but of handsome, well-chosen and well-grown plants, and even variety of level in the various gardens, such as occurs at Bulwick, are all good aids.

The nearness of an interesting kitchen garden with sheltering walls is a source of beauty and infinite variety, but this is just what does not occur in every place, and many houses are best without it, so that when we have

them is Eulalia, planted at intervals and rising out from among the bright coloured Gaillardias, Celosias, Anthemis, Nepetas, Scabious, &c. For giving a light aspect to a large bed there is no more useful plant than this Eulalia, as its grey foliage harmonises with any colour you choose to place it with. Round these mixed plants were planted two rings, one silver Chilian Beet, and outside this Mrs. Sinkins Pink; in the centre of the bed are Dahlias, Nicotiana gigantea, &c.

Standing on the higher slope and viewing the garden as a whole, you cannot help being struck by the many natural advantages such a garden possesses. Although simplicity itself stamps it in every conceivable way as regards its construction, still the beds, though simple in form, are very bold and well balanced. Then there is the green carpet of Grass surrounding each bed, which of all things is the most becoming in a flower garden. Leading from this garden to the bowling green below are steps; the iron rails, which are old Dutch work, are covered with Ivy, Ampelopsis, and climbing Roses. The effect, especially in the autumn, is very pretty. To the right of these steps, and running the whole length of the wall, is a border of mixed Irises. On the left is another border filled with herbaceous plants, the walls here being covered with Tea Roses chiefly.

#### THE BORDERS.

Retracing our steps, we start again from the higher terrace by the mansion, and, turning to the right, pass through a gateway, with its old chains hanging on the iron gates, the gates themselves seeming as though held open by Gloire de Dijon Roses and other climbers. We notice two beautiful pillars surmounted by two high balls, covered with Ampelopsis. In front of us and running the whole length of the kitchen garden is a fine old herbaceous border, about 150 yards long and 35 feet wide; down the centre is a green sward of Grass about 8 feet wide; on either side is the border backed up by a Holly hedge, with standard Hollies rising at intervals the whole length. This hedge is clipped yearly, the top coming to a point, and is kept about 7 feet high, so that it forms a good solid background to the border. This border and the beds in the flower garden were designed by a lady, evidently a good gardener, assisted by the late Rev. J. M. Berkeley, the naturalist who was then vicar of King's Cliff, a neighbouring village. These borders have been kept very gay through the summer by the use of annuals sown in front and among the older clumps of perennials. Turning to the left from the pillars (we pass an old, large evergreen Oak, bound together by chains, and supported by huge forked branches), we approach what is called the Rose garden; this garden consists of beds running parallel with each other, and one across the bottom. This little garden is surrounded on the north and east by an angle of the garden wall, on the south by a Yew hedge planted twenty years ago, clipped into a pyramidal shape. The bed at the lower end of the garden is planted with Delphiniums (named varieties) and Liliun testaceum clumps alternately; these form the back row; in front of these are planted named varieties of Paeonia sinensis, in front of these, again, are clumps of Spanish Iris and clumps of choice Narcissi. As these bulbs die off, Lobelia cardinalis are planted to follow on, the whole bed being edged with purple Viola Archie Grant.

#### CARNATIONS.

The centre bed in the garden is planted with Carnation Ketton Rose; this is the second year it has flowered in the same place, and on this bed—about 25 yards long and 6 feet wide—

there were when at their best 15,000 good-formed flowers expanded at the same time, a sight to be remembered.

Leaving this snug corner, we pass through an opening in the Yew hedge and enter what should be the kitchen garden; but such was Lady Henry Grosvenor's love for flowers, over half an acre was monopolised here for growing Carnations and like flowers for the house and for sending to hospitals. First we come to what may be termed nursery beds, which earlier in the season were aglow with florists' Tulips, Ranunculi, and Spanish Irises, but are now filled with seedling Hollyhocks, Dahlias, Carnations, &c., the outside bed being used for various species of Roses. Leaving these small beds we come to what may be termed a "garden of Carnations." As we stand on the top of the garden, running in front of us are six long beds filled with Carnations, each bed 60 yards long and 5 feet wide. On the right-hand side and running the whole length of the beds is a hedge of Sweet Peas, on the left the same, with a row of Cactus Dahlias in front of them. The Carnations, which have done exceptionally well, are what are termed hardy border varieties, and as they are grown entirely for cut flowers, no attempt is made at disbudging. As the flowers expand they are cut every morning, or as occasion may require, and that unstintingly. The ground being a good medium heavy loam, no manure is used except for mulching, but burnt ashes in quantity are substituted for the manure, the ground well prepared in the autumn, and all varieties (except Gloire de Nancy or any that there may be a doubt about their hardiness) are planted out in October. Last winter they had no protection. After planting nothing is done (save hoeing among them to keep the weeds down) until they are staked and tied, when if it is dry they have a thorough soaking of water, then directly a mulching of peat Moss and litter from the stable. Respecting the sorts grown, first comes a new one named Lady H. Grosvenor, to which a bed has been allotted. This variety comes into flower long before the general collection, and such is its flowering qualities that most of the grass runs to flower, thus keeping up a continual succession of bloom. The difficulty is to get a good stock of it. Lincolnshire Clove comes next, a late-flowering variety, at its best a fortnight after most others are past. G. F. Sage, the Burn Pink or Duchess of Fife, Duchess of Portland, Mrs. R. Hole, Mrs. Muir, Gloire de Nancy, Germania and Ketton Rose are grown in quantity; then a bed is devoted to French and German-named sorts, amongst which are some very pleasing things. Then another bed is set apart for the trial of new sorts. Perhaps most conspicuous among the Carnations are the pinks, rosy pinks and salmon pinks. There are about 200 varieties, numbering in all about 6000 plants.

#### GRASS-WALK BORDERS.

Leaving the Carnation garden we pass down a Grass walk, which leads into what is called the lower garden. On either side is a mixed border, at the present time gay with Sunflowers, summer-flowering Chrysanthemums, Gaillardias, Cosmids, Cactus Dahlias, &c. At the back of each border are planted sweet-scented Pelargoniums for cutting. Down this border, at intervals of every 8 yards or so, are erected rustic arches, over which are climbing Gourds. Passing on we come into the lower garden, which is used as a vegetable garden. The walk through the centre leads down to the Yew hedge, through which an opening has been recently cut to show the water in the distance. On either side of this walk are hedges of

Sweet Peas forming a background for a border composed of Roses, Cloves, pink and white Stocks, these edged with Musk and white Thrift. On the doorway, and forming as it were a framework for the door-posts, are Lathyrus grandiflorus and Lathyrus latifolius roseus, also two small hedges of that most blue of all Peas, Lord Anson's. The border here on the left is filled with seedling Carnations, about 600. On the right we notice the Indian Maize growing 8 feet high (as a vegetable). The cinder walks being near the water are studded with pot Chrysanthemums (400 being grown). Passing through the door we turn to the left on a Grass walk, which leads us round the outside of the kitchen garden. On the right-hand side of this walk runs a 6-feet border, which is full of Narcissi. In the far corner we notice huge bushes of Nuts, carrying heavy crops. Here Sweet Violets, single and double, are grown for winter flowering in frames, nearly 1000 roots being prepared for that purpose. Passing along we cross the bottom end of the long herbaceous border, where we pause to admire the beautiful iron gate leading out into the park. This gate is reputed to have been made by a blacksmith at the neighbouring village of Deene, and is a splendid piece of workmanship, the design being certainly Dutch. Leaving the gate we come into the upper kitchen garden, which is full to overflowing with vegetables and fruit bushes. Retracing our steps past the greenhouse, we noticed five hedges of Emily Henderson Sweet Pea, each about 40 yards long. Although the flowers have been cut from them by the basketful, still they are carrying a good crop of seed.

In walking round, one of the most striking characteristics of the place is the Grass walks. This is easily accounted for, there being no gravel pits in the locality. Running round the entire length of the outside of the kitchen garden is one, there is another crossing the garden east and west, then there is one down the centre of the long herbaceous border going north and south. The effect of these Grass walks and their charming fringes of border is very pretty.

## FLOWER GARDEN.

#### COLOUR IN FLORISTS' FLOWERS.

WHATEVER may be the difference in the views of Mr. Douglas and myself on the above subject, my desire was simply to prevent its being supposed by anyone not familiar with our flowers that the combination of "rose and purple on a white ground" in a Carnation is rejected by florists. The class represented by this combination of colours is a long-established and a favourite one, and the objection to Mr. Douglas's flower as shown in Mr. Moon's figure of it could only be that it had not enough of the bizarre character in it.

As regards Dorothy, the pale rose flake, I saw it here in the gardens of two of my neighbours, and I noticed blooms of it shown at Kensington for two seasons subsequent to the Slough show. The pale rose markings had dwindled to a few faint patches of colour here and there on an acre of white ground, and it soon dropped out of notice. I am, therefore, justified in my view that it was never as a rose flake more than an imperfectly developed flower. Had it been other than this the colour would have stood as has the colour of varieties like Crista-galli and Sybil, after close on thirty seasons of blooming, just as has that of Mr. Douglas's own grand flower Thalia, which is the queen of all the rose flakes.

Mr. Douglas admits that florists do not exclude from their exhibitions Carnations other than the

bizarres and flakes, but claims for himself the entire credit for providing classes for the selfs and fancies, adding that "the florists opposed them and would have none of them at first." I do not wish to deny to Mr. Douglas his share of credit in the matter, and it may easily have been that there were those among florists who, without disparaging the beauty of the selfs and fancies, thought their young society would have enough to do at first in caring for their own special flowers. Be this as it may, I have heard the late Mr. Dodwell relate more than once that when Mr. Charles Turner and he were contemplating the establishment of the southern section of the National Carnation Society they wrote—in letters which crossed—each suggesting to the other the providing of classes for the self and fancy flowers. In view of this action on the part of the two leading florists of their day, it is scarcely fair to say

florists of the old school of certain varieties because of their shade of colour. I will be quite plain and will not "confuse the issue." Mr. Horner mis-reads me when he says, "It is too wide an assertion to say that in the florist's Carnation we insist that the colours, whatever they are, should be of a dark and not a pale tint." He takes this to mean that I object to rose flakes and pink and purple bizarres in Carnations. On the contrary, I think the rose flakes are the most beautiful of the show Carnations, and have often said so, and I admire the pink and purple bizarres. What I did and do object to is that the strict florist admits, say, Sarah Payne and William Skirving, but throws out Harmony. The judge who did so was brought from the north of England as the best representative from the north. So far from my rejecting the pink and purple bizarres or the rose flakes, I must refer again to the

a "washed" colour when I see it. A Pink can be a pale delicate pink without pallor or suggestion of skim milk.

As to the Auricula, Mr. Horner knows as well as I do that the old Lancashire florists would have none other colour than the black in Auriculas as a ground; consequently they did not follow up any departure from this. The blue ground I think lovely in white-edged Auriculas, and I have seen all the varieties exhibited by Mr. Simonite, and also by Mr. Horner in the south; and if the florists as a body will take up other colours as well as the "black" ground, the Auricula will soon become more popular than it is.

As to the Tulip, Mr. Horner knows all about it, and he also knows that the objections I have raised are not new. I would object to an impure base as much as Mr. Horner would in a feathered Tulip, but the original species—*Tulipa Gesneriana*—has what the florists term an impure base; but they have worked it out, and the base in a garden Tulip is a clear yellow or white; but as this "fault" was implanted there by the hand of Nature's architect, I am not sure that we ought to consider it a blemish. What I would like to see done—and I hope it will be done—is a standard of excellence set up for all our florists' flowers. The Horticultural Society is engaged in this work at the present moment, and I am sure any suggestions from florists would be considered.

The late Mr. Glenn wrote a book on the properties of florists' flowers on the lines of the old florists, with certain modifications. I believe it would be a great help to a judge if every floral society were to publish a complete standard of excellence and a code of rules for judging. This want has always been felt, and I know there is much feeling caused by the mistakes made by judges at the present day.

I have before me a circular issued by a floral society in 1834, in which it states that "in consequence of the disappointments which the cultivators of florists' flowers have frequently met with at the society's exhibitions, by reason of the censors awarding prizes to flowers that in some cases ought to have been set aside as wanting the requisite qualities, and in others by their marked preference for flowers that were but lightly esteemed by the most experienced cultivators, it was deemed expedient to appoint a sub-committee to draw up rules for the guidance of the censors at the society's future exhibitions." The names of the sub-committee might be interesting; they were: James Twitchett, Richard Headly, Adam Finch, Fred. Finch, Samuel Widnall, Edward Catling. They give their views of the standard of excellence in Auriculas, Polyanthuses, Tulips, Anemones, Ranunculuses, Pinks, Carnations, and Picotees. It may be remarked that they say nothing about the stained stamens being a disqualification in a Tulip, but they use the word "must" in many places where I would use "should." In fact, the use of this word "must" by florists being insisted upon when certain points are considered is one of my main objections.—J. DOUGLAS.

*Iris border in lower garden at Bulwick.*

that the establishment of these classes was "opposed by the florists."

I fail also to see the justice of the antagonism which Mr. Douglas seems to set up between the artist or "other tasteful person" and the florist. If the artist admired Mr. Douglas's pink and purple bizarre Harmony, he would also admire Sarah Payne or William Skirving, which are more highly developed flowers of the same class. He would admire in them, just as we do, the symmetry of form, the harmony of colour, and the combined refinement and force which are the characteristics of these fine flowers.—M. ROWAN.

I have received a number of letters from lovers of these fine old garden flowers, most of them from old friends. One or two of them seem surprised beyond measure that I should write as I have done. I will ask leave to make a few more remarks to explain why I wrote and also to show that I had reason on my side.

The Rev. F. D. Horner has also written to the editor, and I would like to point out that he and others have not quite understood me. What I objected to was the total rejection by some

election of varieties just published. Where the rose flake obtaining the highest number of marks was raised by me, and I can add that Harmony has crept up to the third place in the election, two others of the same pale tints raised by me have also obtained places. I suppose the florists are at last getting out of this groove. There is another point upon which I am at issue with the old-fashioned florists. They say that every petal in a bizarre Carnation must have two colours upon it, or the flower must be disqualified. Never mind how beautiful all the other petals may be, as a show flower it must go, unless, peradventure, one spot may be found of the second colour. Let the fault be a point against it if you like, but do not let it be a disqualification. The growers of Carnations are becoming more numerous year by year, and I am constantly being asked to define the distinctions between a florist's Carnation and a border Carnation; whereas I contend that there is no difference. They are all border Carnations. Mr. Horner knows very well that no one insists more upon broad, well-formed petals than I do, and that I have sense enough to know

**Tufted Pansies.**—If we accept this name for those plants that were formerly known as *Violas*, it should, I think, be applied only to those varieties that are really entitled to such a name, and not to those whose habit of growth and power of reproduction more resemble the true Pansy. Take, for instance, that type of flower of which Countess of Kintore and Annie King may be cited as examples. Save for their long-enduring and very free-flowering properties they have little in common with a true tufted Pansy. The profusion and density of growth emanating from the old root are wanting and the liability to split up the old plants into an unlimited number of parts, each with its tiny rootlets, is also wanting. These characteristics are noticeable in many varieties that are now catalogued as tufted Pansies. These remarks must not be taken as intended to depreciate the worth of these particular varieties for the flower garden. On the contrary, they are beautiful and long-enduring. My contention is simply that if *Violetta*, for example, is a true

tufted Pansy, it requires a considerable stretch of the imagination to put Countess of Kintore in the same class. Now that the *Violetta* type is being strengthened each succeeding year, why not put all of similar habit into one class and let the strong straggling growers be known simply as *Violas*? Some of the stronger varieties are noticeable for very distinct foliage, slightly darker and individual leaves at once larger and also firmer and more smooth in texture. I have found this especially in *Annie King* and in a seedling obtained from *White Swan*. A careful inspection of the beds now that the spell of frost is over shows very few gaps in the ranks of the number of plants (rather over four thousand in fifteen varieties) put out last October. Not more than a score are missing, a fact that speaks volumes for their hardiness when we consider that for many nights in February the glass was at zero, or only a few degrees above that point.—E. B.

**Polyanthuses.**—Late-sown seedlings of these that were pricked off on prepared borders will want a little attention as soon as the ground is workable, for unless they were inserted very firmly there may possibly be an upheaval of the small plants and an exposure of roots. Having secured an excellent stock in separate colours, I was able after the flowering season to split up the old plants, and to obtain in this way quite as many as I required. A showery time followed the replanting; the plants came away without any check and threw quite a nice lot of flower throughout the autumn—in fact I was able to cut good trusses until the first frost in January. All the *Polyanthus* family as well as the tufted Pansies will be welcome this spring. It seems probable that other things, Wallflowers and *Silene* for example, will not recover from the frost. A fairly moist spring is the best for *Polyanthuses*, especially on light, dry soil. They were poor, for instance, in 1893, where such conditions existed and good surface mulching and watering were not practicable.—E. B.

**Effects of the frost on shrubs.**—It is perhaps somewhat early to pass a decided opinion as to the damage done, but I should say, although not of a permanent nature, the exceptional weather in February will be answerable for considerable damage to foliage, and also for the destruction of a lot of the earliest buds on deciduous shrubs. Nearly all the *Laurustinus* bloom, whether expanded or in bud, is destroyed, and the buds on either side the shoots three or four pairs down from the top also appear to be badly nipped. I was looking over a big mass of *Rhododendron Nobleanum* lately, and find that all points of the foliage are touched, that is the tender foliage, some half a dozen top leaves. Some out-door *Camellias* that anticipated the season, owing to the mild weather experienced until the new year and made a slight start, have naturally received a rude shock. In the way of deciduous shrubs, I have to record with regret a big loss of buds on the white form of *Cydonia japonica*; we shall miss the sheet of bloom that is usually a prominent feature in the flower garden quite early in the season. The buds, to use an expression common among gardeners, also look very "shaky" on that lovely deciduous shrub, *Spiraea prunifolia* fl.-pl. Matters, however, are never so bad but that they might be worse. If the mild weather of the early winter had lasted a few weeks longer and the severe frost had then followed, I fear we should have chronicled a much heavier loss.—E. B., *Claremont*.

**Starworts.**—As the majority of these bear late division and replanting better than most herbaceous plants, advantage may be taken of the earliest time when the ground is workable to fill up any gaps in borders or shrubberies where their presence would be acceptable. It sometimes happens that in trimming up Evergreens or looking through deciduous shrubs portions of soil may be laid bare by the removal of unsightly or dead branches, and if there are no more shrubs to hand, the gaps can often be filled with the taller herbaceous plants to give a bit of colour, and

there are few better things than Starworts. One can command such a variety in height from 18 inches to 6 feet, and they also possess the merit of flowering satisfactorily the first year if care is taken in the planting. A little good short manure to work round the roots and also as a mulch is advisable. Touching the practicability of late lifting and replanting suggested above and the qualifying statement "some varieties," it may be noted for the benefit of those who are only just starting the cultivation of these plants that there is a wide difference in their habit of growth; some will grow anywhere and anyhow, except perhaps in the poorest and driest of soils, and once established are almost as difficult to get rid of as Couch Grass, whilst others have no rambling tendencies and increase in bulk very slowly. As it is always advisable, if possible, to plant each sort in sufficient quantity to give a fair idea of its merits, the planting may naturally be close or wide to suit the characteristics of the variety. A case in point to illustrate the suggestion here made may be given. *Amellus bessarabicus* and *acris* are two varieties almost identical in height and time of flowering, but whilst a small piece of the former would cover a square yard of ground in two or three seasons if not kept in check, the latter is emphatically a "stay-at-home," and it is a long time after planting before one gets a large clump of it. In justice to this very beautiful Starwort, it may, however, be noted that a surprisingly large head of flower is produced from a comparatively small plant. It was seen in perfection last year, the damp summer having the effect of preserving the individual flowers at their best much longer than usual, besides being answerable for additional vigour in the plants.—E. B.

#### FLOWER GARDEN NOTES.

ADVANTAGE must be taken of the first time the ground can be pronounced in a workable condition to make an inspection of herbaceous borders, with the view to ascertain the amount of damage effected by the frost, and to make provision for repairing the same at the earliest opportunity planting may be practicable. Fortunately, there are not many inmates of these borders that are likely to succumb in ordinary winters, except it may be *Chrysanthemums* and one or two other things that may have fallen victims to insufficient mulching, as *Romneya Coulteri*, or to the neglect of tying up the foliage to protect the heart of the plant, as with *Yucca filamentosa*. This late frost, however, has been so exceptionally severe and prolonged as to play sad havoc with some plants that as a rule come safely through the winter—*Antirrhinums* and *Pentstemons* for example. They may generally be depended on to break away from the stem even if the foliage is crippled, but this frost seems to have gone clean through foliage, branch and stem. Bearing in mind, therefore, the possibility of losses, it is always advisable to have a little stock in hand of really good things with which one may replace such losses. The two species above named as likely to succumb to the frost as well as scarlet *Lobelias*, *Phloxes*, perennial *Sunflowers*, *Starworts* and many other things can all be readily increased either from offsets or cuttings. If these were inserted at the proper time and then potted or boxed, they should now be capital little plants. Of course, in the case of those varieties where there is plenty of stock and division is practicable this mode of propagation can be practised, but where the stock is limited it is often not advisable to mutilate existing clumps, and in such cases the slower, but not less certain mode of propagation is recommended. In the matter of the *Phloxes* care should be taken to make sure before planting whether they belong to the tall or dwarf sections, that they may be assigned respectively to the centre or back of the border. Many of the newer *Phloxes* too throw such splendid heads of flower that it is advisable to so plant that they stand clear of each other. A surface mulching is always to be recommended after late planting, and if slugs are likely to be troublesome, some cocoa-nut fibre or coal ashes—the latter perhaps preferably—may

be placed about the plants or things of a succulent nature, as the *Phloxes* and *Pentstemons* are apt to vanish very quickly.

**SISYRINCHIUMS.**—I should like to say a good word for these, especially *grandiflorum*, where the practice of filling up large beds with herbaceous in lieu of bedding plants prevails. This may be planted in bold clumps, the remaining portions of the bed to be appropriated by some dwarf carpet plant. It is very handsome alike in flower and foliage, the latter, indeed, somewhat resembling that of the *Iris* family. Nor ought the old common variety to be despised for rough ground where choicer plants would fail to give satisfactory results. I have worked occasional clumps into such positions together with *Foxgloves*, *Verbascums*, and hardy plants of a similar character, and once planted, the *Sisyrrinchium* can be relied on to yield annually a plentiful crop of seedlings which can be thinned out early in the season, allowing sufficient to remain to cover the ground. Among the various things used for the site above-named were some large clumps of *Lilium candidum*, and the ground having been deeply worked they have done fairly well. I fancy in their case the check given to early growth may have a tendency to keep the plants more free from disease than is usually the case. One always regrets an early development of foliage, as a cold spell often follows, and a check at this time is invariably followed by the appearance of mildew.

**PROPAGATING.**—As the time for the propagation of tender plants is now drawing to a close, it is advisable to make a thorough inspection of the stock with the view to ascertain if sufficient quantities are to hand of the various things likely to be required, and if any varieties are found wanting to consider the possibility of finding sufficient substitutes. Thus, if there is not enough of the dwarf *Ageratum* or a particular strain of *Lobelia* one can sometimes substitute a good dwarf purple *Viola*, and recourse may be had to the old stock even at the eleventh hour. If it is split up into a multitude of little pieces and planted for a few weeks in a bit of good soil, receiving the necessary attention in the way of watering, &c., it will come in very handy by the end of May. Naturally it will be late coming into flower in comparison with October planted cuttings, and the practice is not to be recommended; the fact, however, remains that deficiencies can be made up in this way. Similarly *White Swan Viola* can be substituted for *Mangles' variegated Geranium*, often a miffy plant to strike, and *Lord Elcho, Bullion, or Prince of Orange* for *Calecolarias* and yellow *Tropaeolums*. Again, in the case of large beds where a certain number of flowering or fine-foliaged plants is to be associated with a carpet of hardy plants, the latter may often be considerably strengthened, the propagation of such things, for instance, as *Antennaria tomentosa*, the carpeting *Sedums* and *Veronica* being of a comparatively easy nature. Very quiet arrangements can be made in this way: a group of *Grevillea robusta* or *Dracana gracilis*, for instance, on a carpet of *Sedum Lydium* or even the old double *Chamomile*, and as an example of brighter colouring, clumps of *Lobelia fulgens* *Queen Victoria* or *Firefly* (the latter would seem to be the strongest of the family) on the silvery *Veronica*. Very nice beds can be obtained for small gardens with some of the *Echeverias*, not in the way of carpet bedding, for the practice of sticking these plants close together on a mud wall and carefully pinching out every flower is greatly to be deplored, but planted thinly all over a narrow border, giving them just the right distance to allow of the flower-stems as they appear to swing clear of each other and showing a little green carpet beneath. I have generally found room for our stock of succulents on a rather poor border that was partially filled with the pink alpine *Phlox*.  
E. BURRELL.

*Claremont.*

**Calla (*Richardia*) *æthiopica* as an aquatic.**—Although occasionally this *Calla* is utilised as a waterside and bog plant, it is surprising it is so little grown as a hardy aquatic, for hardy as such

it certainly is, and a most noble one as well. We have large clumps of it in an artificial lake of eleven acres in extent at a considerable elevation, where they have grown strongly and flowered freely for years, and a number of fresh clumps are annually added—surplus stock of friends who grow them in the orthodox way. Old hampers and such like things are filled with good soil, in which the roots are planted, thence from a boat they are dropped in where the depth of water ranges from 2 feet to 3 feet, and left to take care of themselves. Ere the old baskets are rotten the Lilies have rooted through them and taken hold of the mud and leafy accumulations, of which there is abundance overlying the bottom of the lake, for it is nearly surrounded with extensive Oak woods, and is fed by mountain streams. During the summer months the tufts of lively green foliage interspersed with the noble white spathes are objects of attraction and admiration, and form worthy companions to the peerless white Lilies. This is not a case where extreme mildness of the winter should count in their favour, for skating is almost annually indulged in on the lake, and this year this exhilarating pastime was carried on—and off—for over six weeks. Still, we have no qualms of fear as to the well-being of the Callas in their watery bed, for undoubtedly they will come up and bloom in due course as hitherto. I hope those possessing, or having the management of ornamental waters will muster enough courage to give Callas a trial, for assuredly the result will be satisfactory. Would that the beautiful Calla Elliottiana would become sufficiently plentiful and cheap for employing in the same way.—J. R.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**THINNING GRAPES.**—In early houses the thinning is now an important work, and as such kinds as Foster's Seedling, Black Hamburg, and other early varieties will need constant attention, there should be no delay. To become an adept at thinning, a good eye is necessary to judge of the formation of bunch, as even in Black Hamburg the bunches differ, some being looser than others, so that a strict rule cannot be followed as regards the work. The operator should have a knowledge of the various varieties. Some are very shy setters, and uniform thinning would result in many bunches being too thin. Beginners should proceed carefully and first practise with the free-setting kinds. It is safe to thin twice: firstly when the Grapes are the size of small round Peas, or say a Peppercorn, and again from two to three weeks later, as at that period any stoneless berries or misplaced ones can be removed and more attention paid to tying up the bunches, although I am of opinion many young beginners pay too much attention to this point, as many bunches do not require it if well thinned. Of course, to get exhibition bunches, it is necessary, but these are taken in hand by those who require little advice of any kind. In thinning, the season should be taken into account; summer or early Grapes require less thinning than those required to hang a long time. Close, compact-growing kinds which set thickly are more troublesome, and as these often produce large berries early thinning is important. In many instances I have found it necessary to thin as soon as set, again in a fortnight, and to look over the bunches before the final swelling to remove badly-placed berries, and with late-keeping Grapes to allow sufficient room so that there is no possible chance of the berries binding each other. If at all thick, such bunches will not keep, but soon get mouldy in the centre. Gros Colman, for instance, when well grown produces such large berries, that it is often left too thick, and three thinnings are not too much for late kinds such as described above. In thinning, the operator should begin at the point of the bunch and work upwards, never touching the berries with the hand and using a small

peg or stick to steady the bunch. Any part of the bunch touched by the hair or clothes sets rusty, and in thinning, thoroughly clear out of the bunch blind and small berries at the start or first thinning. The best time to thin is early in the day, but it can be done later, as one can often shade while the work is proceeding. Many are obliged to thin in the evening, as pressure of work does not permit the work to be done in the day. More care is necessary at night, as the houses have more moisture and the berries, if much handled, are robbed of their bloom.

**RUST ON GRAPES.**—This often occurs at this period of the year, and in some houses is worse than others. Iron houses, specially old structures, are bad and more troublesome to keep clear, as the frames of the houses are so contracted by heat and cold and admit such volumes of cold air when the wind is north or east. Early Grapes in such structures are subject to extremes. Sulphur in any form is most injurious, and is often the cause of rust when least expected. If the pipes the previous season were covered with sulphur, the undersides often retain a portion of the sulphur, or there may be portions out of sight. When the pipes are heated and the Grapes are small, they give off sulphur fumes which rust the berries when such fumes cannot escape. Sulphur is often used to counteract red spider, but until the skin of the Grapes is hard it is dangerous. I would advise a little warm water with tobacco or soft soap, sponging the affected parts. Again, many vineries have doors at the side or back, and if not carefully opened admit cold air, which causes rust. Excessive ventilation and syringing have the same tendency. It is scarcely necessary to add that handling of the bunches when thinning is equally injurious, and it will be found that early Grapes suffer from rust much more than others. This pest disfigures the berries, prevents swelling, and spreads if not taken notice of. Many Vines have the rods so close to the glass, that the shoots are subjected to extremes of temperature, this causing a warty growth on the leaves—often, too, mildew. In such houses much could be done by suspending the rods for a time till the weather is more genial with a free circulation of air both day and night.

**PLANTING VINES.**—At this season many Grape growers plant cut-back Vines and in a short time get heavy crops. Planting will be later than usual, not because the plants are later, but through trouble in getting the border into condition, as for some weeks soils have been quite frost-bound. As most growers are aware, the Vine does not push out new roots when the sap is rising, not until there is new wood. This will allow the Vines some few weeks' start, but when cut-back canes are used, plant when the shoots are about 3 inches long, just when new roots are forming. At planting well shake out the roots and spread them out evenly. Avoid deep planting, but in all cases make the soil firm both before and after planting. To prevent undue delay in planting, if the soil should have been in the open, prepare the surface soil or portion next the roots by placing in a warm house and having the lower portion more exposed to the border. Such soil will be fit for planting much sooner than when the border was made at once or in greater bulk. If ripened canes are planted these are often purchased when from 6 feet to 8 feet long, and they are not often required of such a length, but cutting back now is out of the question. If the canes be strong there would be great loss of vigour from bleeding. The best practice is to rub all buds off down to the height required and cut away the naked portion when the new growths are well advanced. These remarks apply more at this date to Vines planted in outside borders, and in most cases there will be no gain by very early planting, the outside soil being very cold. If planted early, protection should be given, a slight hotbed being of great benefit when placed over the roots so as to start them.

**GRAFTING VINES.**—The season is at hand for this work. Many growers now adopt what is termed bottle-grafting, which is simple, no time

being lost in getting the new portion to make a quick growth. Those who require to change any variety can quickly do so; others again can put a new variety on an old stock and gain much time by the operation. The Black Hamburg and Muscat of Alexandria are well-known stocks for grafting, though I need scarcely remark that others are equally suitable. Some excellent results have been obtained from diverse stocks, but in a calendar note as to the utility of grafting the question of stocks does not occur. Scions for use during the next few weeks should be kept quiet till about ten days before grafting. Plunge them in the open ground and place in heat at the time named so as to gently excite the sap. The grafts may be attached to the old rods or to good lateral growth. I advise the latter whenever practicable. The grafts should be fitted together and a slice taken off the scion a few inches long, a corresponding slice being taken off the stock, which should be cut a little deep at the lower portion and a similar cut made in an upward direction in the graft. This is termed tonguing, and gives each a grip. There should be two good buds above the cut or upper portion of the graft, and a length of from 4 inches to 6 inches under the tie or clay. Insert this part in a bottle kept full of water tied to the Vine, this supporting the graft till the union with the stock is firmly made, and the bottle may be left till the Vines have finished growth, when a neat cut may be made. Remove the useless lower wood which supplied the moisture, firmly bind the graft to the stock by matting or coarse cotton, and cover over with clay or prepared grafting wax.

**INARCHING VINES.**—This is only another means of attaining the same end as advised above. This operation can be done with ripened wood or new growth, and if with ripened canes the wood should be on the point of breaking freely, that is, the sap well advanced. Place two portions of growing Vines together, cuts being made as advised for bottle-grafting. Tie firmly together and cover with clay or wax, the upper portion or part above the buds or shoots required to grow not being allowed to make strong shoots. Stop at the fourth leaf, otherwise inarching will prove a failure. To be successful, a pot Vine is generally used for inarching; place it in position against the older Vine. With green wood, inarching with strong pot Vines is often practised, but the wood must not be too soft, rather firm, but not set, what one would term half grown. A slight portion of both stock and scion is cut, the two being neatly fitted together and treated as described for ripened wood. Keep the portion moist, the scion soon taking the lead. The growth from the stock must be stopped at the third joint to allow the scion to grow freely. G. WYTHES.

### THE KITCHEN GARDEN.

**PLANTING POTATOES.**—Although extra care in planting and sowing for first early crops will this year be necessary, all who have warm sheltered borders may now venture to get in prepared tubers of such Potatoes as Sharpe's Victor, Ring-leader, Maximus, or any of the favourite Ashleaf section. I say prepared, as although some do not believe in sprouting early Potatoes, I have myself proved its advantages. The tubers should not be brought forward in Peach houses and vineries, as in the case of frame-planted ones, but in an ordinary greenhouse, so that they are hard and durable, and not liable to feel the fluctuations in temperature likely to occur after being planted. Of course this batch will need protection when through the surface; indeed, I always give it at planting time by employing wooden troughs which stand between the rows in the daytime and are placed over them at night. These keep the ground from freezing and help to retain any sun-heat communicated to the border during the day. Beware of deep planting. Merely draw drills sufficiently deep to allow of the seed being nicely covered. If these are drawn in the forenoon of a fine sunny day and allowed to stand open till the afternoon they will not only be dry, but warm, and

the tubers will have a better start. If potting shed refuse, edgings of walks and drives, burnt refuse and leaf mould were prepared and kept dry as advised earlier in the year, they will now be found invaluable for use in the Potato drills. I prefer to leave about three strong sprouts to each tuber. Some advise two only, but sometimes some of them are eaten off by grubs or fail from some unforeseen cause, and then blanks occur; besides, a fair amount of foliage is essential in these extra early crops to promote a satisfactory root action. I have known good dishes secured by planting between trees close up to south walls, merely inserting the seed a couple of inches deep, and afterwards covering with light soil especially prepared for the purpose, the haulm being shielded from frost by Bracken or litter. In regard to the main crop of garden Potatoes, planting in the majority of cases had better be deferred for the present, as the plots intended for their reception are generally less favoured with warmth from sun heat and the tubers lie inactive for some time, suffering in consequence. The first week in April is a good time for planting these, and even then growth frequently falls a victim to late frosts. Where rough boxes of moderate depth can be made on the premises, some of the more advanced tubers of the early border section may well be planted in these, being then brought on in light positions in orchard houses or late Peach houses as near the glass as possible. These will prevent the probability of a break in the supply between the second frame batches and those from the open air. If a few rows of Sutton's Seedling and Puritan be planted now they will follow quickly on the heels of Victor, Ringleader and Maximus. Any new scarce variety may be made the most of by cutting the tubers into sections, each of these being furnished with one or more eyes. When this is practised it should be done some days before planting and the cut portions exposed to the action of light and air to enable them to dry and in part colour. Some dry sandy soil ought also be placed round them in the drills. If a little soot be incorporated it will aid in keeping slugs off, as these pests often injure divided sets. For all first early short-topped varieties a distance of from 15 inches to 18 inches between the rows, and 9 inches or 10 inches from set to set is sufficient.

**EARLIEST FORCED POTATOES.**—December-planted lots occupying pits and frames will now be coming on apace, the haulm needing support by means of short twigs and the roots increased supplies of moisture supplied in a lukewarm state. A little guano stirred into the surface and watered home is an effectual stimulant, the ammonia arising therefore seeming also to feed and strengthen the foliage. Early closing, so as to husband sun-heat, must be practised until growth assumes a yellowish tint and the tubers are fit to lift. Plenty of fresh air must be admitted on fine days, increasing it at intervals from breakfast-time till noon, and on no account must good night coverings be neglected, even though it be fine and mild at dusk. Any roots which were not forward enough for earthing when the main portion was done must now be seen to, fresh soil being added to the surface rather than mangling the roots by disturbing that between the rows. I always earth up as little as possible, as much soil keeps the roots cold and does incalculable harm. Very forward Potatoes in pots growing in Peach houses or other intermediate structures will already have small tubers forming which will be large enough for use in April. Another and final sprinkling of artificial manure may now be given, and where the tops have run up to an unusual height the leads may be pinched off; this will strengthen the stems and improve the crop generally.

**TRANSPLANTING CAULIFLOWERS.**—Those who still adopt the good old method of planting a number of Cauliflowers of the Early London and Walcheren type in handlights in October usually allow five plants to each light to start with, with a view to thinning out in spring. Where the plants withstood the late severe frost transplant-

ing may now take place. Some leave one at each corner of the light and remove the centre one only, but where the plants are healthy and the land rich this space is scarcely sufficient for the Walcheren, which as a rule grows thicker in the stem and produces larger leaves than Early London. I always leave the three best plants in the handlight and remove the rest for making extra rows, lifting them carefully and planting on light warm soil, dug or trenched in autumn, and scullied several times with forks on sunny days to warm the surface. As March-transplanted Cauliflowers seldom attain to their normal size, 18 inches between the rows and 15 inches from plant to plant will be ample. Lower the balls well to steady the stems, as winds are apt to loosen them at the base, and if once they sway to and fro they seldom do any

Border of fine-leaved early plants, Bulrick, 1894.

good. Protect well with Spruce, Laurel, or Yew boughs, and in case of mild showery weather watch regularly for slugs, dusting between the plants with equal parts lime and wood ashes on their first appearance. In many places handlight plants have been killed, and where this is so the soil within should be well stirred with a hand-fork and the tops allowed to remain on for a few days. It will then be thoroughly warm and in readiness for plants that have been wintered in frames and pits. If these were allowed a moderate depth of soil only, and that somewhat retentive, a layer of manure being under it, on a hard ash bottom, they should lift well with care and suffer but little from the removal. It will be as well to leave the tops of the lights on crossways for a week, after which full exposure on calm fine days will suit

them best. If any plants have been wintered in pots, they may be planted on the most exposed plots, being better able to stand removal than lifted plants.

**CABBAGES.**—Fortunately, the plants in many seed beds were well covered with snow, and so were saved from destruction. As green vegetables are sure to be very scarce, all spare ground should be filled up with the best of the plants, carrying out the work with due care, and drawing up a little earth to the stems, as they are sure to be somewhat leggy. If such Cabbages do not attain to their normal size, which they can hardly be expected to do, not having been previously pricked out, yet they will come in at a most acceptable time, proving most useful. All autumn-planted quarters of Ellam's and other first early sorts should again be gone through, firming being necessary. The Dutch hoe should also be run through the rows, a good sprinkling of artificial manure being first given.

**SECOND EARLIEST CARROTS.**—Where Carrots are in constant demand for soups it is a good plan to sow a few rows of the early stump-rooted section now, as the early protected bed of French or Parisian Forcing sown in February is liable to be much thinned by grubs, fly, or even wireworm. I would advise the sowing of an equal quantity of Market Favourite, Early Gem, and the old Nantes Horn. The first named will lead the way by long odds. Nantes will follow, and Early Gem keep up the supply. No manure, a surface rendered fine by repeated scuffing, and a fairly sunny aspect are the chief necessities for this special crop. Wood ashes may be freely used over the seed before the slight drill is filled in, and the soil made firm by treading and re-treading. The main crop sowings must be deferred until April, and for early, mid-season, and latest crop more seed than usual sown, as it was harvested in an unsatisfactory condition last season.

**SEEDLING LETTUCE.**—Few even of the so-called hardy old Brown Cos planted out under walls last October have survived even where afforded a little protection. Young seedlings, therefore, which were sown in heat in January or February will need special care in order to save them from becoming leggy or damping off. Presuming that due thinning was performed as soon as they could be handled, and that they were removed from their germinating quarters to a temperature a few degrees less, they will now be in a fit condition for pricking out into boxes or on a slight hot-bed, preferably the latter. Let the soil be fairly rich and made firm, pricking out about 4 inches apart and keeping the frame close for a few days. After this a confined atmosphere must be avoided, all the air possible being admitted by tilted lights until free growth has commenced, when their entire removal on fine days will be imperative. If a spare light or two is at hand, All the Year Round may be allowed to mature in them, this being of very rapid growth and much esteemed for salad.

**UNPROTECTED RADISHES.**—The time has now arrived when open-air sowings of Wood's Frame and French Breakfast may be made without the necessity of covering at night. Choose an open sunny spot and work it well with a fork to secure dryness, sow broadcast and cover but slightly, finally treading and raking the surface, and fixing a fish-net over the bed for protection from chaffinches. If this is neglected in wooded districts not one seed will be left.

**BEANS FOR COOL FRAMES.**—Although not generally practised, it is a good plan to sow a batch or two of French Beans in pots, at first giving them comfortable quarters, and as soon as 3 inches of growth have been made, remove them to a frame which can be kept rather close for a time and be well covered at night till the second or third week in April, when they may be finally transplanted into cool pits or home-made frames, any spare odd lights being used to cover them. A 4-inch pot is the best size to sow in, and this should be done thinly, as, unlike those transplanted into heated beds, they do not like to be separated. A sunny nook or corner sheltered by

fruit or plant houses or high walls, and having a due south aspect, is necessary. The soil must be thrown into the frames some time before planting takes place so as to be well warmed. This is most important, as, if planted in cold compost, French Beans not only do indifferently, but frequently canker at the base of the stem and naturally rot. A little guano stirred in helps them much, it being of a warm nature. Fowls' manure incorporated with fine soil in winter and stored away in a dry shed is also an excellent stimulant for Beans and all heat-loving crops. They should be planted far enough apart in the rows to allow of a slight earthing-up, as then the tops will not need the aid of sticks. Newington Wonder, Syon House, and Mohawk are all excellent for this sowing, being hardier than most other sorts and not growing too tall.

**ENDIVE.**—Lettuce being so scarce, those who have still a good frame of Bread-leaved Endive are fortunate. In order to make the most of it, remove it to a north aspect and bed the balls in quite dry soil or leaf mould; wet soil would encourage rot in such a position. This removal will prevent it running to seed, which it is apt to do at this date when in a sunny place. Do not draw off the lights, but merely tilt them, as if once rain falls on the leaves and gets into the heart it will perish in such a position.

**ROOT SHED.**—This should now have its final overhauling, as many things, notably Salsafy and Scorzonera, will be losing their vitality and shrivelling. In order to stay this as much as possible, relay in fresh soil containing a good amount of moisture. J. CRAWFORD.

## GARDEN FLORA.

### PLATE 1006.

#### TALL RUDBECKIAS.

(WITH A COLOURED PLATE OF R. NITIDA.\*)

THE tall Rudbeckias are useful in the garden during late summer and early autumn, especially if they are taken out of the mixed border with its usual restriction and planted in masses among shrubs or grouped in a free and simple way. Large groups of such easily grown free-flowering plants as these are most valuable for creating distinct effects of colour even in distant parts of the garden.

**R. NITIDA**, here figured, is one of the handsomest of the tall-growing kinds, and though by no means new, it is decidedly rare in gardens. It has large leaves of a decided glaucous tint, and its flower-spikes reach a height of about 6 feet. The spikes are few-flowered, but the flowers individually are of fine size, rich yellow in colour, with the disc florets disposed in a cone-like receptacle. Doubtless the illustration here given will cause some attention to be bestowed upon a neglected, but admirable species. It is also known under the name of *levigata*.

**R. LACINIATA** is another handsome species which grows 6 feet or more in height, and has been thought a poor weedy subject when seen as a half-starved tuft standing in the same place a decade or more. Planted as advised above and new groups made from time to time, it is a brilliant late summer flower. Its leaves are deeply cut and the flower-spikes bear many flowers, not quite so large as those of the preceding kind, but of a soft clear yellow colour.

**R. CALIFORNICA**, another fine species, growing about 6 feet high, has flowers of a rich yellow colour, larger and broader in the petal than those of *laciniata*, with a distinct cone in the centre like an Acorn.

**R. MAXIMA** is one of the largest cone flowers, and in rich soil grows as high as 9 feet. Usually,

\* Drawn for THE GARDEN by H. G. Moon in Messrs. Barr's nursery, Long Ditton. Lithographed and printed by Guillaume Severeys.

however, it does not exceed 6 feet in height. It has large oval leaves; the lower ones, borne on long stems, are of a distinct glaucous green shade. The stems are often terminated by one large bloom, but if branched they only produce a few flowers each on a naked stem 15 inches to 18 inches long. The long ray petals droop when the flower is fully expanded and accentuate the characteristic effect of the cone in the centre, which projects sometimes as much as 2 inches above the yellow rays.

A. H.

## KITCHEN GARDEN.

### EARLY & LATE PLANTING OF POTATOES.

ON all sides one hears of the determination of growers to defer the planting of the main crop until later than has been the custom. This determination is a wise one. Apart from the fact that the late planter stands a better chance of his crop escaping the action of the frost, it gives him a longer time to prepare the ground, and therefore it is likely to be in better condition to receive the sets. One cannot but think that many growers have been long in learning this lesson, but it seems now that the destruction of the haulm by the frost last season has brought it home to them in a forcible manner. Anxiety appears to be directed now as to the latest time it is safe to defer the planting without prejudice to the crop. Locality, I think, should decide this point in most cases. Here in the west of England very excellent crops are obtained by planting at the end—or thereabouts—of the third week in April. But here again the district may be advantageously taken into account. In hilly districts it is quite safe to plant ten days earlier than in the valleys. I may also direct attention to a point that has often been urged before. I refer to planting the late varieties first and the early sorts last. There is a good deal of reason in this, because it enables the cultivator to push on the work of planting earlier than he otherwise could. It is quite clear that more attention should be given to the preparation of the sets, and the sooner that is set about the better. Those who have them in caves or stored in close frost-proof structures should get them uncovered, and, if possible, spread out thinly on the floor of some building where they will be safe from frost. The thinner they lie the better condition they will be in for planting. If light and air can reach the sets in mild weather it will be an advantage, as they will be kept cooler, and consequently will not become exhausted by sprouting. In their anxiety to keep Potato sets free from the late severe frost many people placed their stock in barrels and boxes and stored them away in warm sheds and other safe places. Such a step was a wise one and all very well while the frost lasted, but if they are kept in such places long after the frost has left us, the sets will begin to sprout and all the shoots will have to be rubbed off to separate them. The result will be a considerable weakening of the sets. The stock of tubers for seed will well repay for going over now, and wherever the conditions are likely to promote an early growth the sets should be removed to cooler and more airy quarters.

Opinions appear to differ somewhat as to the value of large sets over small ones. This is a question that should be decided by the condition of the ground. If it has been well prepared, then moderately sized sets are equal to large ones. In no case do I favour selecting small ones, but in indifferently prepared land

rather large sets will always give better returns than small ones. The same kind of reasoning holds good with regard to cut sets. In well cultivated soil cut sets are equal to whole ones, but where the land is crude and lumpy uncut tubers are decidedly the best. Very few large growers in the west of England—and there are many that plant from ten to twenty acres—cut their sets. If they cut any it is only the largest, and these invariably have the best position in the field. J. C. CLARKE.

**Sutton's Favourite Lettuce.**—This is one of the best Lettuces for summer use, the hearts being very crisp and solid. For withstanding the drought also it is of much value.

**Good Broccoli in winter.**—Last season and this have been the only two years I have been able to cut Snow's Winter White at Christmas from the open ground. I am not so fond of this variety as Veitch's Self-protecting Autumn Broccoli. By sowing this early in April and again a month later there is a succession, and one is more independent of Snow's, which is more variable as to turning in. At page 41 "W. G. C." says Veitch's Self-protecting never disappointed him. Such is my experience, and I only wish we had as reliable varieties for January, February and March. I admit such varieties as Model and The Queen are reliable, but these are spring kinds and equally valuable as the Protecting Autumn variety. Even these fail in severe winters if not protected. Unless one can command frames it is useless to place late kinds in sheds or in a dark place, as they do not form their heads. "W. G. C." does not mention Leamington, a self-protecting February Broccoli. This I find hardier than others. Cooling's Matchless is also fine for March, but, as previously stated, I cannot say they are quite hardy.—S. M.

**Cauliflower Pearl.**—So far I am very pleased with the behaviour of the young plants of this variety sown in autumn, and wintered under glasses and in frames. While many of the older sorts have already buttoned, not a single plant of Pearl shows any tendency to do so. The centres are keeping close and erect—always a good sign at this period, as if once these commence to spread out, buttoning prematurely is almost certain to follow. The plants of Pearl seem also to be pretty hardy, being very little damaged by the recent severe frost. This variety comes in just after Walcheren and Early London, which is just what is wanted, as when once these early batches commence to heart in, they do so with a rush and are soon over. Throughout the spring and summer a little of Walcheren and Pearl should be sown at each sowing, half of each being finally planted out, and thus a succession secured.—J. C.

**Early market Peas.**—In market gardens in this district the first crops of Peas are now above ground. Growers for profit are naturally anxious to be as early as possible, for one week only makes at the present time a great difference in the price. The first consignments will make about 15s. per bushel, but this high figure cannot, owing to the enormous acreage given up to Pea culture now-a-days, be long maintained. In the course of a fortnight the price will often drop to less than one-third of that amount. The light soils of this part of Surrey favour the production of early Peas, but there is, of course, a great element of uncertainty about them. Sometimes melting snow succeeded immediately by severe frost will completely ruin large breadths. I have known one man lose 20 acres in this way. Those who grow Peas in a large way can afford to speculate, and if an early crop fails in this manner, there is time enough to make a fresh sowing, and it is merely an affair of the cost of seed and labour. Even if the very early sowings pass safely through the winter they have spring frosts to contend with. Last season the early crops in the home counties were to a great extent destroyed, thousands of pounds' worth being lost to

the cultivators of this esculent. In a general way the early part of February is soon enough to commence sowing, and crops put in at that time will frequently overtake those sown six weeks earlier, and in nine cases out of ten the yield will be more satisfactory.—J. C., *Bygfoot*.

**French Beans.**—The more of these brought on under glass the better, as, arriving at maturity in a short time, nothing is better for filling such a gap as must occur in early outdoor produce this year. Now that the season is getting advanced a stove temperature is not needed for successional batches, so that any intermediate house where pots or home-made boxes can be accommodated and placed where the light and sun can reach them will answer. *Ne Plus Ultra* and that good old variety *Syon House* are, perhaps, the two best for the purpose. If these are sown thinly in rather large pots, and judiciously fed as soon as the first pods are formed, they will continue to yield for a long time. Do not give much water until growth appears, to avoid rot. Support with stout branching sticks when about 9 inches high, and if there is any probability of the haulm out-distancing the supports, pinch the leads. Fill up the pots or boxes with soil at the start, leaving no margin for earthing up, as this process, while involving extra labour, is of no benefit whatever. In order to keep the foliage free from spider, syringe the underside freely on fine days. *Ne Plus Ultra* may now be sown where more heat is applied in addition to *Syon House*, larger pots being used all round, and more manure added to the soil at sowing time than is advisable for the earlier batches.

**Forcing Carrots.**—The correspondence on the merits of different varieties for forcing has been very reasonable and interesting, and I should like to add one more sort to those already named, as I believe it has not been mentioned. It is *Holborn Long Forcing*, and when it becomes better known will be in considerable demand, as it combines great earliness, fine quality, and a desirable shape. Most of the early Carrots are of the *Scarlet Horn* type, but the above is more after the intermediate class, and for that reason will be in favour on many gentlemen's tables. It grows as quickly as the earliest varieties, and is a decided acquisition to those gardeners who are expected to supply long tender roots about the size of a rat's tail for as long a season as possible.—W. G. C.

#### GREEN VEGETABLES.

GREEN vegetables of all kinds will be scarcer this spring than has been the case for many years. I do not remember to have witnessed such destruction among winter greens. Brussels Sprouts, generally so reliable, are quite ruined. Broccoli has not a particle of life in it, and the hardy Kale family is so crippled as to be of but little use. Even Turnip greens, on which one can in a general way rely for an abundant supply of fresh greens in early spring, will be scarce, whole fields of roots being reduced to pulp. What makes the matter worse is that autumn-planted Cabbages are either killed off or in such a plight that we cannot expect much from them. Large breadths of Peas are completely ruined, so that gathering will be delayed for several weeks. Those who have the command of artificial warmth should at once sow some *Heartwell Early Marrow Cabbage*, or when this convenience does not exist, the seeds may be raised in a cool greenhouse or sown broadcast in a frame. The plants, if hardened off and set out in rich ground, will make rapid progress. Spring-raised Cabbages will frequently overtake those put out in autumn, especially if they are carefully transplanted and watered in dry weather. They may be set out about 8 inches apart if plenty of plants are at command, and every other one can be cut when half grown. This will give a supply of young greens quite a fortnight sooner than would be the case if one waits until the plants are well hearted. Swede greens are by no means to be despised in a season like this. Though not so delicate in flavour as Turnip greens, they are

tender and very wholesome. Those who have the opportunity should get a bushel or two of roots and plant them in a sheltered spot. They will soon start into growth and will furnish a supply of succulent greens. Spinach should be sown at intervals of ten days, and if a good breadth of Rape is put in there will be something to rely on till the young Cabbages are ready. Rape is really a tender, toothsome and wholesome vegetable.

*Bygfoot.*

J. C.

## ORCHIDS.

### DENDROBIUMS.

ONE might almost be satisfied with a good collection of these Orchids alone, so varied are the habits of growth, manner of flowering and colour of the blossoms. The majority of the species come from the tropics and may be accommodated in one house, with a little care in arrangement and slightly differing treatment for the various species. The best known of the genus is that section with cylindrical pseudo-bulbs of varying length and thickness, from the tiny growing *D. pulchellum* to the large and noble *D. Dalhousianum* and *D. moschatum*. Between these there are many intermediate forms. Some are evergreen, as *D. Brymerianum*; some lose their leaves in autumn, as *D. Bensonianum* and *D. Wardianum*; while others, such as *D. nobile*, though not strictly deciduous, usually lose their leaves the second year. All these, with the exceptions noted below, require a brisk moist heat during the growing season with an abundance of sunlight, the blinds being let down during the hottest part of the day only. The house should be closed early during this period and the blinds drawn up, so that the temperature rises in the middle of summer to 100° or more, the plants being well syringed overhead and every available space damped to cause a thoroughly humid atmosphere, the moisture settling on the glass and preventing scorching of the foliage. As soon as possible in autumn, when the growths are approaching completion, the shading must be entirely dispensed with and the plants arranged as near the glass as possible to thoroughly ripen and consolidate the stems. By the time the last leaf is produced on such as *D. Wardianum* the stems should be hard and scaly in appearance, betokening that all that is necessary to ensure a beautiful bloom in spring is a long period of dry rest in a cool house. There should be no hurry in removing these plants from the house in which they have been growing. It is far better not to remove them at all than to do so too early, for if the temperature is decreased before the pseudo-bulbs are thoroughly ripened, but few flowers will be produced, and even these will not be of good quality. When they are, however, quite finished the temperature can be gradually lessened, at the same time reducing the supply of water at the roots as the leaves fall, until in winter, when the stems are bare, little or none will be needed. The evergreen species with stem-like pseudo-bulbs will not require quite so much drying in the winter, otherwise the treatment of these may be identical with that of the deciduous section. Those with shorter pseudo-bulbs bearing the leaves chiefly near the top, as *D. densiflorum* and *D. chrysotoxum*, will be better arranged a little farther from the glass, and, although requiring plenty of light, need not be subjected to such a high temperature in autumn. These do best during winter kept in the house in which they are grown, and should be moderately moist at the roots all through the season. *D. speciosum* is an exception to this rule, as, unless the growth

of this is well ripened, no flowers will be produced. When the pseudo-bulbs of this kind are finished the plants may be turned out of doors for a time and there kept until there is a danger of early frosts. Our plants are usually out until the middle of September, with a mat or some light protection on cold nights, and these never fail to flower profusely. *D. formosum*, *D. eburneum*, *D. infundibulum* and *D. Jamesianum* seem never to rest, and it is best to let them have their own way, not drying them much at any season, but watering according to the state of growth. The two first-mentioned species of this—the *nigro-hirsute* group—delight in a strong, moist heat and plenty of sunlight, but the latter kinds are better kept cool. They will grow with the *Odontoglossums*, but thrive better in a rather higher temperature, or such as suits the Mexican *Laelias*. They should be grown in small pots, and nothing stagnant or sour must be allowed about the roots. By the appearance of the roots a fairly good idea may be obtained as to the size of pot or basket and the description of compost best suited to the various kinds. Take *D. Devonianum*, for instance; its roots are small and do not seem inclined to push far in search of moisture, preferring rather to grow closely matted together. Clearly a large pot would be a mistake here, what is required being a small one, with the compost used in a much finer condition than for *D. nobile* or *D. Brymerianum*, whose roots are larger and more ambitious, liking a large pot, with good rough lumps of charcoal, potsherds and turfy peat. There may be exceptions to this rule, but, taken as a guide, it will not lead the cultivator far wrong.

R. S.

**Sickly Dendrobiums** (*J. A. Dearden*).—If the temperature has not fallen lower than 45°, the mischief has undoubtedly been caused by the fogs, which render the culture of these delicately textured Orchids yearly more and more difficult in the vicinity of large manufacturing towns. This temperature is, however, far too low for *Dendrobiums* with flowers so far advanced as those you send, and if accompanied by much atmospheric moisture would be very detrimental. Keep the roof glass clean by frequent mopping or a stream of water from the hose, change the air in the houses daily and as early in the morning as possible without lowering the temperature. The action of the sun upon the plants with the night moisture about them is often productive of injury to delicate flowers and young growing shoots, and if a little air is given early in the morning it dissipates this and mitigates the evil.—H. R.

**Cypripedium villosum aureum.**—I have received a very fine flower of this variety from Mr. J. Crispin, of Chester Park, Fishponds, near Bristol, who says the plant from which it was cut was somewhat checked by removal for exhibition. The flower, nevertheless, measures 5 inches across the petals, which are broad and of great substance; the upper portion of these and the lip are suffused with bright yellow. The dorsal sepal is very much broader than in the type, measuring about 2 inches across. The broad, deep purple line extends more than half-way up, while the ground colour is a greenish-yellow, fading to white at the apex and margin. The flower is very massive and this fine variety possesses all the well-known good points of the type. A very fine plant of this variety was recently in bloom in the Hornham Cliff collection, the flowers being very large and bright in colour.—H. R.

**Goodyera discolor.**—This Orchid is admirably adapted for growing in a warm, moist and shady stove, the leaves taking on a most delightful velvety sheen, which shows to great advantage associated with *Fittonias* and other brightly-coloured plants of a similar habit. The flowers are not large, but very pretty, and the spikes when thrown well up—as on strong plants

they would be—are very attractive at a dull season, *i.e.*, from December onwards to April. The flowers are pure white, with a yellow column; the leaves broad at the base, rounded, and tapering to a point. They are green on the upper surface, with a silvery-white midrib, the underside being reddish or purple. Few Orchids are more easily propagated than this. If a couple of good stock plants in large pans can be procured they may be cut over biennially and a good stock gradually worked up. The growths may be taken off with as many roots as possible attached, at the same time leaving as much as convenient of the rhizome to produce breaks for another season. These may be placed in pots or pans of varying sizes, from six to eight being placed in the 8-inch size, with less or more for smaller or larger pots. These may be placed in a brisk, moist heat in the stove or in a propagating case not kept too close. Water must be carefully given until the roots are beginning to run in the compost; afterwards a good supply will be necessary, as the plants grow quickly and require plenty of nutriment. The compost should consist of equal parts of good peat, fibrous loam and chopped Sphagnum Moss, with enough finely-broken potsherds to prevent closeness. In the winter the plants must be kept somewhat drier at the root, but not sufficiently so to cause injury to the foliage.—H. R.

#### GALEANDRAS.

This genus of deciduous terrestrial Orchids is not represented in our collections so much as it really deserves, for although there are some species possessing but little beauty, there are also some with lovely blossoms. Galeandras are closely allied to Eulophias and Lissochilus, the principal distinction being in the formation of the lip, which is contracted into a broad funnel-shaped spur. There are not more than about half a dozen species known to cultivation, and these are all natives of Tropical America; therefore they require strong heat and plenty of moisture to grow them successfully in our gardens. Whilst in active growth these plants thrive best in the East India house, where they should be supplied with plenty of water at the roots and the atmosphere well charged with moisture. When the flowers appear, a cooler and drier temperature, such as that of the Cattleya house, will suit them best, and where they should be allowed to remain for a period of rest. Being deciduous plants, the leaves turn yellow and drop off in the autumn, and as soon as the foliage commences to change colour water must be gradually diminished, and only sufficient given to keep the bulbs in a plump and healthy condition. Naturally these plants grow in well-decayed leaf-mould, but the best results can be obtained by using a compost consisting of good fibrous peat and Sphagnum Moss to which should be added some good decomposed leaf-mould. The pots should be thoroughly drained, and when repotted the plants should be elevated somewhat above the rim. Galeandras have been found somewhat difficult to cultivate, which is no doubt the cause of their not finding so much favour as many other kinds of Orchids. They require great attention throughout the year, especially in watering and keeping clean, for whilst in growth the foliage is very susceptible to the attacks of red spider and thrips, which cause much damage if not quickly removed. The finest species in this genus is certainly

*G. DEVONIANA*, a native of the banks of the Rio Negro. It there attains a height of 5 feet and 6 feet, but under cultivation it seldom reaches much above 2 feet high. The pseudo-bulbs are slender and erect, clothed in a young state with lanceolate sheathing leaves. The peduncle

appears from the top of the stem, and supports a pendent raceme of flowers which individually measure about 4 inches across. These will last a long time in full beauty. The sepals and petals are of a purplish brown colour, usually striped and margined with light green, the tube-like lip white, striped with purple, and forming a handsome contrast to the other dark segments. This fine plant was first discovered by Schomburgk upwards of sixty years ago, but it was not until about thirteen or fourteen years later that living plants arrived in this country.

*G. BAUERI*.—A very rare and desirable plant. This is the typical species upon which the genus was established by Dr. Lindley. It grows to nearly 2 feet in height, and is furnished with fine lanceolate foliage. The flowers are produced on a drooping inflorescence, the sepals and petals being brownish yellow, whilst the lip is yellow, lined with reddish brown. It was first introduced about 1840 by Messrs. Loddiges, of Hackney.

*G. NIVALIS*.—This is also a very desirable and rare plant, which appears to have first flowered in the collection of Sir Trevor Lawrence, Bart., about thirteen years ago. It is also a native of Tropical America and of very dwarf stature, the pseudo-bulbs not growing above a foot in height. The flowers each measure about 2 inches across, the sepals and petals being of a brownish green, whilst the lip is white, with a small purplish blotch in the centre of the base.

*G. BATEMANI*.—A very dwarf growing and distinct plant, which was introduced from Mexico over fifty years ago. It has also been since found in Guatemala. The plant grows to a height of about 6 inches and is furnished with very long leaves, the raceme being similarly produced as in the other species, terminal, and many-flowered. The sepals and petals are similar and of an olive greenish colour; the large lip is purplish rose with a white margin. WM. HUGH GOWER.

*Ceologyne cristata alba*.—The pure white form of this well-known Orchid is not nearly so rare as formerly, but one does not often come across such a fine plant as is now in flower at Hornham Cliff. The plant in question is in a large wooden basket, and is carrying upwards of a dozen spikes, each bearing from four to six of the beautiful pure white blossoms. Other noteworthy Orchids in flower here are *Odontoglossum crispum*, a good variety 4 inches across, the sepals and petals broad, and of the purest glistening white; *Dendrobium primulinum*, a fine specimen covered with flowers; *D. Ainsworthii*, and among other varieties of *D. nobile*, a fine plant of *D. nobile pendulum*, well flowered, but, unfortunately, tied up so that its elegant pendulous habit could not be seen. The flowers of this last are very bright magenta with a deep purple blotch on the labellum.

*Oncidium Cavendishianum*.—The spikes of this species are not so graceful as some others in the genus, but its very distinct appearance, combined with its free-flowering habit and the fact that it blossoms during the winter months are all points in its favour. The species produces no pseudo-bulbs, but grows in tufts of healthy-looking, deep green leaves, from the bases of which the racemes spring. The individual blossoms are upwards of an inch in diameter and thickly produced upon the long branching racemes. They are golden yellow, with spots of chestnut-red. *O. carthaginense* and *O. roseum* are occasionally met with under the name of *Cavendishianum*, but they are quite distinct kinds. A nice form of the golden-lipped variety was in flower in the Hornham Cliff collection recently. *O. Cavendishianum* thrives well in pots, with rather a shallow compost consisting largely of Sphagnum Moss, and should be carefully watered during the winter. It thrives best in a light position in the Cattleya house and lasts many weeks in full beauty.

*Odontoglossum Harryanum*.—This fine Orchid is now plentiful enough to be represented in all collections, and its unique characters and undoubted merits entitle it to this distinction. It

is a native of the United States of Colombia, whence Messrs. Horsman and Co., of Colchester, first received it in 1886. This was, however, a small importation only, it being found in quantity soon after by Messrs. Sander, of St. Albans. *O. Harryanum*, although not difficult to grow, is one of those species that when in good health it is wise to keep it so, for if once the plants get out of condition they are a long while recovering. It dislikes disturbance at the root, and in repotting, a compost that will not become sour should be used. The pots should be clean and well drained and just large enough to take the plants easily. One part of good peat fibre to two of Sphagnum Moss with plenty of finely broken crocks will suit it well, and the base of the leading pseudo-bulbs must be kept a little above the rims. When first imported it should be given a place in the Cattleya house. Even when established it likes a rather higher temperature than the crispum section, although this is not absolutely necessary. I recently saw a very fine plant of this species growing in a house that occasionally fell during the recent severe weather to 40°, and in summer is kept as cool as possible by free ventilation and shading, a house, in fact, wherein the coolest section of the genus does well. The flowers, produced on long racemes, are each from 4 inches to 5 inches across and delicately scented. Sometimes these do not open well, but this is probably owing to weakness, as it is most frequent in plants out of health. The sepals are brown with greenish yellow bars and spots, the petals similar in ground colour, but more freely marked. The lip is quite distinct from that of any other *Odontoglossum*, being large, pure white, marked with blue lines, and with a good deal of yellow about the crest. It flowers at various seasons of the year, and the oft-repeated advice respecting leaving the flowers on the plants too long is specially applicable to this species.—R.

**The Cattleya grub.**—As I have heard several complaints as to the prevalence of this pest this season and also seen its depredations in several collections of Orchids, it may not be out of place to warn inexperienced cultivators to be on the look-out for it and to at once sacrifice the leads that are attacked. No good purpose can be served by leaving them on, but a good deal of mischief may on the other hand be caused, not only on account of the grub itself, but because the longer they are left the less likelihood there is of obtaining good breaks from the affected pseudo-bulbs. The presence of the grub is easily seen by the club-shaped growth, abnormally swollen at the base and pointed at the apex. Newly-imported plants, or those of the second year, appear to suffer most, and all the labiate section seem to be especially subject to it. Some growers are in the habit of fumigating for this pest, others burn lights in the houses to attract the female fly, but it is questionable whether any good results accrue. Prompt action in removing and burning all affected growths, in bad cases taking the plants out of the pots and washing every part in tepid water, are the likeliest means of extermination.—R.

#### THE SCARLET LELIAS.

THOUGH taking this as a heading, I am thinking more particularly of two capital examples of *Laelia harpophylla* of which cut spikes were sent to the last R.H.S. Drill Hall meeting. It is a matter of regret that this showy species is not more plentiful, for it is certainly one of the best when well managed. The two spikes above referred to seem to point to there being two forms, one being quite a major variety. The rich glowing orange-scarlet flowers, practically self-coloured, are at this season a decided acquisition, lasting a considerable time in good condition. It is not one of the most attractive plants when out of flower, but this is not everything. Being of only moderate growth it should be kept well elevated above the pot so that the air can act in a more favourable manner. It is not so compact in its habit as *L. cinnabarina*, but the flower-scape is much shorter,

nor has it been so long in cultivation, having been introduced about 1873. *L. cinnabarina*, on the other hand, has been in cultivation some sixty years, yet this is, like *Lælia harpophylla*, far from common. It forms a good succession to *L. harpophylla*. I have seen it frequently in good condition in May. Mr. Geo. Baker when gardener to Mr. Ambrose Bassett at Stamford Hill used to show it in fine condition in May, and I have also noted it in June also. Its flower-scapes are frequently more than 18 inches in length, the blossoms, clustered towards the apex, being, relatively speaking, smaller than those of *L. harpophylla*. Only a year or two since it received a first-class certificate from the Orchid committee of the R.H.S. *L. flammea* is a scarce hybrid between *L. cinnabarina* and *L. Pilcheri*, being thus a hybrid of the second descent, the latter parent being itself a hybrid between *L. Perrini* and *L. (Cattleya) crispa*. *L. flammea* is also known as *L. Veitchi*; thus its origin is easily detected. It has the sepals and petals of a most vivid orange-scarlet with a crimson-purple lip, thus showing its descent from *L. crispa*. *L. flava* is more strictly speaking a yellow species, but it belongs to the same section, being similar to *L. cinnabarina*, but dwarfier. *L. monophylla* is quite a dwarf species, having relatively small flowers with orange-scarlet sepals and petals, also the labellum. This species is from Jamaica, whereas the others are of Brazilian origin. *L. xanthina*, a summer flowering species, has blooms of an orange shade as large as those of *L. cinnabarina* and flowers in a similar manner. This section of *Lælia* is well worthy of more attention than is at present given it.

## ORCHIDS.

***Lælia superbians.***—A nice piece of this grand species is at present in flower in the Cambridge Lodge collection, where it appears to thrive well, this being the third spike of bloom it has produced in less than two years. The individual blooms measure nearly 6 inches in diameter, and in this plant the flowers appear to be very pale, being of a light rose. The lip is deeper in colour than the other segments and veined with purple, the throat yellow. This species was introduced by the Royal Horticultural Society in 1842, but it appears to have been first discovered by Mr. Ure-Skinner about three years previously in Guatemala.—W.

***Cœlogyne cristata alba.***—This lovely variety of *Cœlogyne* has become more plentiful during recent years. Unfortunately it is of a more straggling habit than the typical form, and therefore does not make such a well-shaped plant. During the present season several well-flowered plants have been noticed, but the finest specimen I have ever seen is now blooming in the Cambridge Lodge collection, Camberwell, where a fine piece measuring upwards of 4 feet through is carrying twenty-nine fine spikes of five and six blooms each. This plant is grown in quite a cool temperature throughout the year in the same structure as *Lycaste Skinneri*, and where the ventilators are always wide open during fine weather, thus proving that it is not necessary to give these Orchids such strong heat as is often recommended.—W.

***Cypripedium concolor.***—This species and its allied kinds have in many instances suffered severely during the past winter in many of our collections through having been placed upon shelves near the glass where the frost has reached them. This would not have happened had the plants been kept in a perfectly dry state. I recently saw a fine batch of *C. niveum*, *C. concolor* and *C. bellatulum*, which had been wintered in a cool house where the ice was inside the house within a couple of inches of the plants. These, however, had been kept dust-dry, and had not received any water from the beginning of Decem-

ber until about a fortnight ago. They certainly looked none the worse for having been kept dry. In some cases where the plants were kept in a moist condition they were entirely killed, and in others the excess of moisture upon the leaves has left very visible effects. It will be interesting to hear later in the season what effect this severe drying off will have upon the flowering.—G.

## SHORT NOTES.—ORCHIDS.

***Dendrobium Wardianum album.***—One of the finest forms of the pure white variety comes from Mr. Broome, of Llandudno. The flower is large and of good substance, with a yellow throat, the two small spots at the base being very faint, the remaining portion of the flower of the purest white. It is the best white form I have yet seen.—G.

***Lycaste Skinneri alba.***—Amongst pure white Orchids in flower at the Forest Hill Nurseries is a charming variety of this. The plant here referred to is of fine form and good substance, the flowers pure white, saving the lemon-yellow tinge on the throat. A small piece of *Cœlogyne cristata alba* was also very noticeable for the large number of flowers on it.—W.

***Dendrobium rhodostomum.***—I lately noticed

A bed of Carnations (Ketton Rose) at Bulwick, 1894.

a plant of this Veitchian hybrid in flower. It is a cross between *D. Huttoni* and *D. sanguinolentum*. The flowers measure fully 2 inches in diameter, the petals broader than the sepals, both white, tipped with purplish-crimson, the lip also marked like the other segments, but with a larger blotch and a maroon disc on the throat.—W.

***Cypripedium Ashburtoniæ expansum.***—This is one of the most beautiful *Cypripediums*, the dorsal sepal broad and very flat, of an apple-green colour and veined with brown, with an exceedingly broad margin of pure white. The whole surface is beautifully spotted with deep brown, the petals sparingly spotted with dark warts. A fine variety is now in flower with Mr. R. J. Measures at Camberwell.—G.

**A fine *Odontoglossum crispum.***—Will you kindly inform me the name of the *Odontoglossum crispum* I now send? I fancy the variety is unique. I have never seen a *crispum* with such pure and beautifully white sepals and petals. I bought the plant two years ago and it has now flowered for the first time.—W. MARSHALL.

\*\* The flower sent is a very refined form of *O. crispum*, viz., *O. e. virginale*. It is not unique by any means, but still not common and well worth taking care of. The flower lacks width in the petals and substance, but this latter may be due to its having been open a long time. It is, nevertheless, a chaste and beautiful form.—H. R.

## STOVE AND GREENHOUSE.

## CAMELLIAS CASTING THEIR BUDS.

THE early months of the year are very trying for Camellias, and it is during this period that many buds fall. There is more than one cause for bud-dropping, but it does not often occur with plants that have their roots in good condition. When the whole collection suffers in this way it is a sure sign that the treatment generally is wrong. I have seen a whole houseful of Camellias which were full of buds at the commencement of the winter and in robust health almost flowerless when they ought to have been full of bloom. This was caused by too high a temperature being maintained during the dull months. Camellias are very impatient of artificial heat, and, unlike Azaleas and some other hard-wooded things, cannot be forced into bloom. It is not safe to exceed a night temperature of 50° from November till March, and a rise of 5° in the daytime in sunless weather is quite enough. When bud-dropping is confined to certain plants it will generally be found that their roots are in a more or less inactive condition. This may be caused by over-

potting, unsuitable compost, or injudicious watering. Plants thus affected should be marked and examined when done blooming. In the case of medium-sized specimens this is an easy matter, as by turning them out of the pot the condition of the roots can be ascertained. If these are not numerous and black at the tips, as much of the old soil as possible should be worked away, replacing in a pot just large enough to contain the roots, and using a compost of fine peat with plenty of white sand in it. With careful watering fresh healthy roots will quickly be made and the plants will take a fresh lease of life. This simple operation will frequently suffice to restore lost vigour and prevent bud-dropping. Camellias do not need much pot room, and should never be repotted unless the soil is quite filled with roots. I have known plants to remain without change of soil for ten years and every season give a full crop of bloom. These root-bound specimens require, however, good attention in the matter of watering. Plants of this description often cast a portion or the whole of their buds through the soil not being quite moist enough when the buds are swelling. Enough water should be given when necessary to thoroughly soak the ball of earth. In the case of such root-bound specimens, unless some of the moisture escapes from the drainage hole, enough has not been given. It is a curious fact that

weakly Camellias are apt to form a quantity of buds. If these are all allowed to remain it will frequently happen that not a single one expands. Early in autumn such plants should be disbudded, leaving one bud only to a shoot. J. C.

**Bignonia venusta.**—This is a lovely creeper, and one that should be planted where shade in an intermediate house is required. The specimen at Syon House rarely fails to flower profusely, and is very beautiful for a roof when allowed to fall down in festoons, and there is no severe tying in of the growths. To show how well this plant will thrive in a low temperature, I may remark that the temperature of the house in which it grows has often been under 50, and at the roof much lower, the house being lofty. It grows freely, producing its funnel-shaped, long-lasting flowers in quantity. When grown in stoves, as often advised, it does not thrive so well, being very subject to thrips and red spider. Given, however, a warm greenhouse, it succeeds with little trouble and is a pleasing object. The plant at Syon House is probably the oldest in the country.—VISITOR.

**Pleroma macranthum at Kew.**—The value of this plant at Kew has frequently been noted in THE GARDEN. We have few plants which bloom at this season so freely and of a similar colour, the rich purple-blue flowers being very handsome, a succession being produced on the same shoot. This old plant was formerly known as *Lasiandra macrantha*, and was often recommended as a suitable subject to cover a wall or pillar in the stove, but I do not advise this treatment. At Kew it is blooming freely in the greenhouse, the flowers being more lasting and more freely produced in this way. There is less trouble, too, with insect pests. Grown as a bush it is very effective and far better than long straggling plants without any leaves at the base. To obtain flowering plants in 6-inch pots, cuttings, taken off now with a heel, struck in bottom heat in a sandy compost, three in a 3-inch pot, and potted on when rooted, using more loam at the last shift, if grown in cold frames during the summer will flower all through the winter in a temperature of 55°.—VISITOR.

**Zonal Pelargoniums for winter.**—I read with interest the notes on these and other soft-wooded plants for winter flowering by E. Burrell (p. 103). He names a few zonals which he finds most suitable for winter blooming. I give a few which I find suitable, viz., E. V. Raspail, Mme. Thibaut, Guillon Mangilli, Richard Dean, Imogene, Zelia, W. H. Williams, Mme. Leon Dolly, Lotus, and a semi-double variety which I do not know the name of. I cannot speak well of Queen of the Belgians as a winter bloomer. I prefer striking the cuttings in autumn in preference to the spring, as I find by so doing a better foundation is laid. I do not agree with E. Burrell when he says that the summer quarters for these plants should be pits from which Potatoes, &c., have been lifted, and that the Pelargoniums should be shaded in hot weather. I would not shade zonals were it not to preserve the blooms. After having been finally potted, my plants are stood out with the Chrysanthemums where they get the full sun three parts of the day. When the pots are full of roots the plants receive a little liquid manure about twice a week, all blooms being picked off till the plants are housed in the autumn. A good batch of *Primula obconica* is useful during the winter months associated with the other things mentioned at page 103. I prefer sowing a pinch of seed each spring with the Chinese *Primulas* to dividing the old plants.—R. NAILOR, *Roughy*.

**Thyracanthus rutilans.**—This is one of the good old-fashioned plants that have been in many cases ousted from their position in the garden by less meritorious subjects. In many places, however, they still find a home, and their beauty is much appreciated. At Burford Lodge many uncommon but desirable plants are well done, as may be seen at the meetings of the R.H.S., for Orchids are by no means the only subjects grown

by Sir Trevor Lawrence in his Surrey garden. From thence was sent to the meeting of the R.H.S. on February 12 a specimen of *Thyracanthus rutilans* which was greatly admired, and deservedly so, as the pendulous racemes of bright crimson tubular-shaped blossoms are very unlike those of any other occupant of our houses. From the way the flowers are produced it must be grown as a standard, for it is only in this manner that the drooping clusters of blossoms are seen at their best. Cuttings are easily struck in the spring, and should be grown on freely during the season. The same plants may be kept and flowered in a satisfactory manner for years. This *Thyracanthus* needs the temperature of a stove in the winter, but during the summer months artificial heat can be dispensed with. According to the "Dictionary of Gardening," the correct name of this plant is *T. Schemburgkianus*, introduced from Grenada in 1855 and known in gardens as *T. rutilans*, the true *T. rutilans* being a native of Colombia, from whence it was introduced in 1851. The genus *Thyracanthus* is one of the *Acanthads*, and it is singular how much the members of this order, despite their showy blossoms, are neglected in gardens. Perhaps this is to some extent owing to the fact that they are unfitted for use in a cut state, as they so quickly drop under such treatment.—H. P.

**Ceanothus under glass.**—It is now several years since I first saw some of the forms of *Ceanothus* brought on under glass and employed for the embellishment of the greenhouse, and though they are seldom used in this way, yet they supply a colour but little represented among plants in bloom either in the stove or greenhouse, while among forced shrubs they stand out by themselves. Some flowering examples of *Ceanothus dentatus* and *C. Veitchianus* are now in No. 4 greenhouse at Kew, and their bright blue blossoms, although not particularly numerous, are very distinct and pleasing. Certainly greater use might be made of them in this way, for their neat growth and deep green foliage render them, irrespective of blossoms, decidedly ornamental. If grown for flowering in pots, a neat, bushy habit of growth should be the object aimed at, and the plants should, of course, be grown in the full sunshine in order to induce the formation of flower buds. The best examples I have ever seen were some bushes of *C. Veitchianus*, that were kept altogether in pots, and plunged out of doors during the summer months. If lifted from the open ground in the autumn and needed for flowering in the following spring, the plants should be potted as soon as possible in order to encourage the formation of roots before winter sets in.—T.

#### WINTER-FLOWERING PLANTS FOR THE CONSERVATORY.

**ACACIA DRUMMONDI** flowering in 5½-inch pots is at the present time a pleasing object, the soft saffron tint of its Bottle-brush-shaped blooms when borne in quantity being very effective. The culture is simple, and by stopping at intervals good bushy specimens may be obtained in small pots. These plants will come into flower during January and February. *Pimelea spectabilis* is a very old introduction, but is now-a-days seldom seen. It bears umbels of white flowers about 2 inches in diameter at the end of the shoots, of which in dwarf well-grown specimens there should be from twenty to thirty. This *Pimelea*, with *P. Nieppergiana*, a pretty but rather smaller-flowered species, is now in bloom in the greenhouse, and constitutes a welcome change from the ordinary occupants of the shelves at the present season. *Chorezema Lowi* should be grown in every garden where a bright conservatory is needed at this time of the year. Small plants with their shoots smothered in flowers are easily obtainable, and the effect of the brilliant Pea-like blossoms is enhanced by the deep green of the prickly Holly-like leaves. The blooms last a long while in perfection, and well-flowered sprays are very valuable for indoor decoration. *Boronia*

*heterophylla* is a charming winter-flowering plant, its slender branches being studded with carmine blooms somewhat the shape of the individual bell of the Lily of the Valley, though lacking its spreading rim. But perhaps *B. megastigma*—on account of its delicate perfume called by some the violet-scented *Boronia*—is to be preferred, for though its flowers are inconspicuous, one plant is capable of filling a room or small conservatory with its delicious odour. All the foregoing subjects are easily grown and do best in a compost of peat and sand. *Cytisus racemosus* with its wealth of clear yellow flowers is now indispensable in the conservatory. Young plants are the most satisfactory both in length of raceme and quantity of bloom, and if well attended to during the earlier stages of growth shapely specimens can be produced with but little trouble. This *Cytisus* is not particular as to soil, loam, leaf-mould and sand suiting it well. In Devonshire it grows out of doors without protection all the year round, but it is never so valuable as in the conservatory during the first two months of the year.

S. W. F.

**Begonia semperflorens gigantea.**—We have now a great number of widely diverse forms of *Begonia semperflorens* in cultivation, but the bold-growing kinds to which the name of *gigantea* has been applied owe their origin to the intercrossing of that species with the Mexican *B. Lynchiana*, first distributed under the specific name of *Roezli*, and as such a coloured plate of it was given in THE GARDEN, August 25, 1883. M. Lemoine was, I believe, the first to cross these two *Begonias*—at all events, he was the first to put the progeny thereof into commerce. The plants are of a strong, bold habit of growth, more nearly partaking in this respect of the character of *B. Lynchiana* than of their other parent. The continuous blooming qualities of this strong-growing strain is a great point in favour of the members of it, as if needed they could, by growing on successional batches, be had in flower all the year round. It is, however, in autumn, winter, and early spring that the blossoms are most valuable, and at any time, but more especially during the dull season, a bold group of flowering examples forms a very ornamental feature in the greenhouse or conservatory. The flowers are borne in large, massive clusters, so that even though the plants are somewhat liable to run up without branching much, they must not be stopped too freely, otherwise the clusters will be much smaller and a good deal of the distinctive features lost.—H. P.

**Boronia heterophylla.**—This has deservedly become within the last few years one of the most popular hard-wooded plants that we have, and no wonder, for it is not difficult to grow, and its beautiful brightly coloured blossoms are borne in great profusion. The flowers are not so fragrant as those of *B. megastigma*; still they emit a very pleasing perfume, which must be enjoyed without disturbing the plant, as the leaves if agitated in any way have a heavy, disagreeable smell, which is by no means desirable. The blossoms of this remain fresh and bright for a long time if shaded from the hottest sun, and this is a great point in favour of this *Boronia*. The sober-tinted *B. megastigma* must on no account be passed over, as its little bell-shaped blossoms, delicately poised on slender stems, are so fragrant, that a single bloom can for this reason be detected for some little distance. Its scent, too, seems to be admired by nearly everyone, which is not always the case with flowers remarkable for their fragrance. While noticing the above-named species of *Boronia*, the merits of such as *B. serrulata* and *B. elatior* must not be overlooked. The two last flower somewhat later than the others mentioned.—T.

**Begonia manicata.**—Some three years ago when a *Begonia* conference was held at Chiswick several papers were read on the subject, among others one of especial interest by Mr. Watson, of Kew, in which he enumerated the best fifty species of *Begonia*, and as there are about 400 species known to botanists, it is evident that it was

necessary to reject many in compiling that list. *B. manicata* finds a place therein, and deservedly so, for it is just now one of the most ornamental species we have, its pink flowers being borne in great profusion. This *Begonia* is not seen at its best when grown as a small plant, that is in a pot 5 inches in diameter, but as a large specimen it is very effective. This is owing to the fact that the individual blossoms are but small, and though borne in considerable numbers on loose branching panicles, they do not make much of a display when only two or three flower-spikes are borne on a plant, but a large specimen bearing a great number of flowers forms a very ornamental object in the cool end of the stove or the intermediate house. The stems of this species are short and of a stout, succulent nature, while the smooth shining green leaves are decidedly ornamental. A singular appearance is presented by peculiar fleshy scale-like hairs of a brownish colour, which are freely borne on the undersides of the leaves and also on the leaf-stalks. There is a variegated form of this, *aureo-maculata*, in which the leaves bear large blotches of yellow, but it is not very constant, and even at its best I prefer the ordinary green type. *B. manicata* was introduced from Mexico in 1842.—H. P.

#### CYCLAMENS AT HORNHAM CLIFF.

As usual at this season, there is a very fine display of Cyclamens at Hornham Cliff, Salisbury, the residence of Capt. H. Greenwood. About 250 plants are grown, and these, although not large, are models of careful and skilful culture. The foliage is bright, large and prettily marbled, in some cases almost hiding the pots, and the plants are literally covered with bloom. Hundreds of buds will apparently prolong the flowering season until far into April or May. The varieties are chiefly of the giganteum strain, the Giant Crimson and Giant White being remarkably good flowers. They are large, the former deep crimson-lake in colour, the latter of the purest white, the flowers very full, owing to the great width and substance of the petals which are well thrown back. Besides these and other self-coloured flowers there are many with a deeper colour at the base, one with flowers bright salmon-pink above and deep purple below, being very striking and a novel break. Vulcan is bright rich crimson, not so large as the giant strain, but very free and of a good habit. White Butterfly has the segments spreading when partly open, and is in this state charming, while when fully open they are recurved as in the other kinds. Mr. Robey prefers sowing the seed at the end of January rather than in late autumn, and though some may be inclined to dispute this point, the results attained abundantly testify to the wisdom of the course pursued. His reason is that the plants are more easily kept growing, and all who have had experience in Cyclamen growing know how important a point this is, how easily the plants are checked and the mischief that is thereby caused. The seed is sown in 6-inch pots in rich, light, loamy soil and placed in a propagating case. As soon as the young plants have made about three leaves they are placed in 3-inch pots and arranged in low frames as close to the glass as possible. They are encouraged to grow freely, a moist genial temperature being always kept up about them, and they are never allowed to get dry at the roots. The frames are carefully ventilated and shaded during the summer months and the plants placed in their flowering pots in August. These will vary in size from 5 inches to 8 inches according to the size of the plants. Mr. Robey is not in favour of the planting-out system, but prefers to keep the plants in pots all through the season. The compost used consists of a third good sound loam, an equal quantity of partly decayed leaf soil, a sixth part each of peat and dried cow manure, with a good sprinkling of clean, coarse silver sand. After potting, the plants are returned to the frame, kept rather closer for a time, and watered sparingly until the roots are again on the move. As soon as these touch the sides of the pots liquid

manure is supplied, well diluted at first, increasing the strength by degrees as the plants advance into flower. The plants are not kept after the second year, as the younger seedlings are found to be much more vigorous, quite as free-flowering, and in all ways more satisfactory. R.

#### FEBRUARY IN SOUTH DEVON.

DURING the month of February the temperature on the grass fell on every night of the twenty-eight below the freezing point, and on March 1 frost had been recorded for the thirty-five days immediately preceding. The greatest amount of

has amounted to but 0.01 of an inch during the month, being 2.73 inches below the average of the last sixteen years and 1.71 inches below the record for February, 1894. Curiously enough, the rainfall for February, 1891—the blizzard year—was exactly similar to this year's measurement, viz., 0.01 of an inch, though the sunshine experienced at that time of exceptional fair weather was far in excess of the average. The rain measured during the two past months amounts to 4.11 inches, as against 6.21 inches recorded during the two first months of last year. At every change of the moon a change in the weather was hoped for, but the moon brought nothing but disappointment. On the 24th an alteration seemed imminent.

Border in lower garden at Bulwick.

frost registered was 15° on the 12th. The mean temperature of the month gave 9° below the average of the last sixteen years. The wind blew from the north or east—and generally with considerable force—for twenty-three days, its total horizontal movement, as indicated by the anemometer, being 7,000 miles, the greatest hourly velocity being recorded on the 4th, when between the hours of 7 p.m. and 8 p.m. a rate of 29 miles per hour was reached.

The sun has shone during 83 hours 55 minutes (this being 1 hour 40 minutes above the average) against 89 hours in February, 1894. The sunniest day was the 28th, when 9 hours 40 minutes, or 91.6 per cent. of the possible sunshine for the day, was recorded. Rainfall, or rather snowfall,

The morning was sunny and warm, and the wind, for the first time for many weeks, came out of the west. The moon was to change that afternoon, and the weather-change so confidently predicted seemed well-nigh assured, when in the afternoon, in a rain-squall from the clouds that had banked up on the horizon, the wind flew into the north-west, and by nightfall had steadily worked its way round to the frozen north again, and by the next morning 8° of frost had been registered on the thermometer. Great havoc has been worked amongst tender shrubs and plants in the gardens, but of these losses it is well not to speak until the genial spring weather—which must arrive ere long—shall give us the opportunity of compiling a correct list of the killed and wounded, at what

time we hold our annual roll-call. Of flowers there have been practically none, with the exception of a few Snowdrops, Crocuses and Winter Aconites, which in sheltered corners found themselves standing a-shiver, with no possibility of retreat, in the bitter wind. S. W. F.

## SOCIETIES AND EXHIBITIONS.

### ROYAL BOTANIC.

MARCH 20.

The first show of the present year was held on Wednesday, but, owing to the backward state of the season, there was a falling off in the number and extent of the exhibits. Miscellaneous groups added greatly to the extent and interest of the display. In one of the chief classes, that for a collection of hardy herbaceous plants, Mr. T. S. Ware, the only exhibitor, was awarded first prize. He had a charming selection, the best among them being *Primula cashmeriana*, *P. rosea*, and *P. denticulata alba*, Dog's-tooth Violets, *Muscari botryoides* in blue and white, the Carpathian Snowflake, *Trillium grandiflorum*, *Sanguinaria canadensis*, and numbers of *Saxifraga Burseriana*, perfect tufts of pure white blossoms, making an admirable finish to the front of the group. Mr. R. Scott, gardener to Miss Foster, The Holme, Regent's Park, was first for a group of greenhouse Azaleas, the second prize lot coming from Mr. H. Eason, gardener to Mr. B. Noakes, Hope Cottage, Highgate. The only group of Cyclamens was from Mr. T. Petridge, Boston Park Nursery, Brentford, to which the first prize was awarded. The plants were profusely flowered. Mr. Douglas secured first prize for twelve pots of *Polyanthus Narcissus*, the same for twelve Hyacinths, and for twelve Tulips. He showed fine varieties in grand form. A selection of the best will be found in the report of the Crystal Palace show. The best group of *Amaryllises* came from Mr. H. Perkins, gardener to the Hon. F. W. D. Smith, Henley-on-Thames. There were some fine kinds, especially Charles Penny, deep rich crimson, and Countess of Arran, light red. Mr. J. Douglas was second. Crocuses grown and shown in wide shallow pots made a brilliant display. A magnificent lot that obtained the first prize came from Mr. R. Scott. White Queen, pure white; Margot, light feathered lilac-blue; *Purpureus grandiflorus*, deep self purple; Albion, and Sir Walter Scott were all very good. Mr. Douglas was second. For a group of Deutzias, Mr. Douglas was first with a fine even lot of plants most profuse in blossom. The only lot of Lily of the Valley came from Mr. Scott, and was awarded first prize.

Among the miscellaneous contributions the group from Messrs. B. S. Williams and Son was very conspicuous. Clivias were a strong feature, two new varieties, Firefly and Model, the former bright red and the latter a softer shade of the same colour, showing distinct advances upon older kinds. *Dendrobium nobile albiflorum*, *Cypripedium Williamsianum*, *C. Chamberlainianum*, *C. Boxalli atratum*, *C. Morgania*, *Miltonia Roezli* and its white form, *Vanda tricolor*, *V. suavis*, *Cymbidium eburneum*, and *Calanthe Sanderiana* were the best among many Orchids well shown. *Boronia megastigma* in quantity diffused its pleasant fragrance. A silver medal was awarded. Messrs. Williams also exhibited floral designs, baskets of red Anthurium with white Lilac, and pink Roses mingled with dark crimson Carnations being noteworthy. This exhibit also received a silver medal. Messrs. W. Paul and Son, of Waltham Cross, were awarded a silver medal for a good collection of Camellias in pots and cut blooms, also Rose Duke of York and other new kinds. A beautiful group of flowering and fine-foliaged plants was arranged by Messrs. J. Laing, Palms, Crotons, Caladiums, and Dracenas being intermixed with *Lycastes*, *Dendrobiums* and *Cattleyas*. Clivias, Begonias and other flowering plants added to the beauty and effectiveness of the exhibit. A silver medal was awarded. A small,

but very interesting group of new and rare plants came from Messrs. J. Veitch and Sons, Chelsea. *Cypripedium Brysa*, with green dorsal sepal, twisted rosy petals and a lip having rosy dots on a white ground, was a pretty hybrid; also *C. Aphrodite*, of which the general colour is whitish, with rosy-purple suffusions. *Phaio-Calanthe rosea*, described in THE GARDEN of March 16, p. 190, was also shown, and *Cymbidium eburneum Lowianum*, carrying a fine spike of flowers. *Streptocarpus gratus* is a new variety with a leaf about 15 inches in length and 4 inches in width, the plant having many branched trusses of rosy-purple flowers. *Amaryllises* in fine deep-coloured kinds, as Milton, bright red, Eurasian, crimson-red, were very good. Some handsome *Rhododendrons* of the javanicum section were, Apollo, bright red; Brilliant, crimson; Minerve, fawn yellow; and Optime, deep fawn, with rosy margins to its petals; the flowers individually and the trusses remarkable for their size. *Raphia vinifera*, a new Palm with leaves like those of the Kentias, the leaflets having small bristles along their edges, was another interesting plant in this group. Messrs. Peed and Sons, of Norwood, sent a large group of fine-foliaged and flowering plants, to which a bronze medal was awarded, and Mr. Jannoch, of the Lily Nurseries, Dersingham, Norfolk, exhibited Lily of the Valley, finely grown and arranged in his usual effective style. Daffodils and other spring flowers, including *Scillas*, *Chionodoxas*, *Freesias*, and *Anemone fulgens*, made up a bright group from Messrs. Barr and Sons, a bronze medal being awarded. Mr. Ware also received a bronze medal for a large group of the best Daffodils, trumpet and star-flowered kinds. Mr. J. R. Stevens, Hassoek's, showed a Strawberry named Stevens' Wonder, and a certificate of merit was granted it. A description of this Strawberry was given in THE GARDEN of March 16, p. 192.

A full prize list will be found in our advertisement columns.

### CRYSTAL PALACE SPRING SHOW.

MARCH 16.

The first show of the season was not a very extensive one, but if the exhibits were lacking in number, the quality of them left nothing to be desired. Probably Daffodils of the trumpet section have never been better shown than they were by Mr. Howe, and it is satisfactory to see that these are receiving more attention. The class for the trumpet-flowered kinds is apparently a new one, and the quality of the exhibits it brought out should induce the authorities to make it permanent. Bulbs were quite the leading feature. For thirty-six Hyacinths Mr. James Douglas, gardener to Mrs. Whitbourn, Great Gearies, Ilford, Essex, was first with a grand exhibit of well-finished spikes. *La Grandesse*, white; King of the Blues and Sultan, deep blue; Princess Mary of Cambridge and Electro, light blues; Garibaldi, rich red, one of the finest of this colour in cultivation, were remarkably fine. For thirty-six Tulips Mr. Douglas was again an easy first with an even exhibit of great excellence and embracing a wide range of colour. Among the kinds shown, Joost van Vondel, white, was very fine. For length of flower and purity of colour this is certainly the best white Tulip we have, but it is unfortunate that another Tulip of a different colour bears the same name. *Proserpine*, rosy crimson; *Fabiola*, rose flake, a fine kind giving variety to the predominating selfs, and *Ophir d'Or*, rich yellow, were all noteworthy. Mr. W. Howe, gardener to Mr. H. Tate, Park Hill, Streatham Common, was second. Mr. Douglas was again first with twenty-four *Polyanthus Narcissi*, showing a fine lot. Among them Mont Ceis, a compact variety which usually produces two and three spikes to a bulb, is certainly one of the best of this section, and has a deeper yellow cup than Grand Monarque. *Bazelman major* and *Adonia* were also fine, this latter the best of any of the yellow-flowered kinds. Mr. Howe was also second in this class. In the Daffodil section Mr. W. Howe

was first with a magnificent exhibit of twenty-four pots, and all so good that it is hardly possible to single any out for special mention, except *maximus*, which, usually a shy kind, was here shown as profuse as any other kind and of telling effect with its rich yellow colour. Sir Watkin, Horsfield, and Ard-Righ were also good. Mr. J. Gibson, gardener to Mr. E. H. Watts, Devonhurst, Chiswick, was second. In this exhibit a pot of Golden Spur calls for special mention. It is one of the best yellow Daffodils and was finely shown. For thirty-six Cyclamens, Mr. J. G. Mowbray, gardener to Major the Hon. H. C. Legge, Fulmer, Slough, was first with a splendid lot, remarkable for the fine size and profusion of the flowers, especially the whites. Mr. Douglas was again first for twelve *Amaryllises*, Mrs. Laing, red, with white throat; Mrs. Douglas, soft feathered red on a white ground; and Erato, deep red, being the best kinds. We notice, however, both in this and the second prize lot which came from Mr. Howe a great preponderance of spotty or splashed flowers that are poor and ineffective as compared with the noble selfs. For twelve *Cinerarias*, Mr. Douglas was first with dwarf large-flowered plants, but not quite at their best. Mr. J. Slater, gardener to Mrs. Nothard, York House, Lower Sydenham, was second. Nine trained specimens of *Mignonette* of medium size, but admirably grown, from Mr. W. Barrell, gardener to Mrs. Thornton, The Hoo, Sydenham Hill, were awarded first in the next class.

Messrs. J. Laing and Sons, of Forest Hill, were first for a group of stove and greenhouse flowering and fine-foliaged plants, but the rather absurd limitations as to space altogether prevented effective grouping. There were many good things in the group; among Orchids, *Culogyne cristata alba*, *Lycaste Skinneri alba*, *Cattleyas* and *Dendrobiums*, and of greenhouse plants, Heaths, Azaleas and Begonias. Mr. Mowbray put up an excellent group of Cyclamens, arranged with a few small Palms and Ferns, the plants dwarf and abundantly flowered. It was the only exhibit in the class, but fully merited the first prize awarded.

In the smaller classes Mr. J. Gibson was first for twelve Hyacinths, with fair spikes of medium size. The first prizes for twelve Tulips and twelve *Polyanthus Narcissi* were also secured by Mr. J. Gibson. For twelve Cyclamens, Mr. W. Slo-grove, Gatton, Reigate, was first, and Mr. F. Watts, gardener to Mr. O. J. Trinder, Mount Vernon, Caterham Valley, second. There was little competition for Lilies of the Valley, but Mr. Lane, gardener to Mr. E. H. Coles, Burnt Wood, Upper Caterham, was first with an admirable exhibit, the leafage abundant, the spikes long, with large flowers thrown well up above the leaves. Mr. J. Bateman was first with twelve Chinese *Primulas*, dwarf, free-flowering specimens, but chiefly white.

The miscellaneous exhibits from the trade considerably augmented the interest and extent of the show. Messrs. W. Paul and Son, of Waltham Cross, exhibited *Camellias* largely, both flowering plants and cut blooms, also a number of plants in pots of their new Monthly Rose Duke of York, which evidently is also a good Rose for forcing. Some new and unnamed Tea Roses were also shown, the plants in pots and having several blooms. One that looks promising was named *Sylphe*. It has a long, full flower of fine shape and delicate colour, pale flesh-pink, shading to white externally. Messrs. J. James and Son, of Farnham Royal, Slough, exhibited a group of *Cinerarias* in their usual excellent style, the plants characterised by compactness, great size of bloom and exceedingly rich colours, especially among the selfs. Mr. T. S. Ware, of Tottenham, brought a large and varied group of spring flowers. Many kinds of trumpet and star *Narcissi* in pots were shown, and *Saxifraga Burseriana* in quantity attracted much notice, the little silvery tufts being almost hidden with a profusion of pure white flowers. Solomon's Seal, a most useful thing for forcing; the Carpathian Snowflake, *Colchicums*, *Bulbocodium*, *Cyclamen coum*, *Arum sanctum*, and

A. Eggeri (to which a first-class certificate was granted), Dog-tooth Violets, and a large mass of *Primula denticulata alba*, also certificated, were most noticeable among the many good things. Messrs. Peed and Sons, of Norwood, contributed a large group of fine-foliaged and flowering plants, and from the same firm came wreaths, &c., of which the body consisted of a grey Lieben with the flowers arranged in one part only. This was a most interesting exhibit, a charming variation from the conventional methods of making such things. Miss Jackson, of Upper Norwood, showed a beautifully arranged basket of cut Daffodils and Snowdrops, also bouquets, &c. Messrs. Laing and Sons, of Forest Hill, sent a group of coloured-leaved plants, the variegated form of *Nicotiana glauca* being well shown. The variegation is very distinct, pleasing, and well defined. The entire leaf is of a grey-green colour with a white margin of varying width around its edge. *Saxifraga sarmentosa tricolor superba* is a long-winded name to give to a pretty form of an old garden favourite. *Bertolonia E. Pynaert* was also shown in good form and colour.

A complete list of awards appears in our advertisement columns.

#### THE NATIONAL DAHLIA SOCIETY.

THIS, one of the oldest of the special societies having its headquarters in London, held its annual meeting at the Horticultural Club, Hotel Windsor, on the 7th inst., there being a good attendance of the leading exhibitors of the Dahlia. Mr. E. Mawley, the chairman of the committee, presided. After the usual preliminaries the hon. secretary (Mr. T. W. Girdlestone) read the report of the committee, which set forth that the ideal Dahlia season is yet to seek; that of 1894 cannot be said to have been an easy one for cultivators. The plants were late in starting into growth and the sunless summer did not help the plants to get over their backwardness. Fortunately, however, the annual exhibition of the society at the Crystal Palace fell on the latest possible date and the display of Dahlias of all classes was a fine one. The feature of the exhibition was undoubtedly the magnificent display of Cactus Dahlias, whose beauty, development, and variety were quite unprecedented, and the effectiveness of the exhibits of the Cactus and single Dahlias was further greatly enhanced by the new arrangement adopted at the exhibition of breaking up the usual long lines of tables by occasional octagonal groups, composed of the collections staged in some of the principal classes. The details of the numbers of the show and fancy Dahlias staged will be gathered from Mr. Mawley's analysis. The society have to deplore the loss of one of the patronesses in Lady Henry Grosvenor, who took the keenest interest in the raising of seedling Cactus Dahlias.

The financial statement showed that there had been received as subscriptions £52 7s., as donations £25 14s., from the Crystal Palace Company £50, advertisements in schedule £13 14s. These amounts, with the balance in hand of £9 9s. 2d. from last year, showed a sum of £151 4s. 2d. on the receipts side. Under the head of expenditure the sum of £133 12s. had been paid as prizes, including a disputed amount of £6 10s. left over from 1893, cost of printing, £15 3s. 11d., small sums £1 19s., leaving the scanty balance of 8s. 6d. only in hand.

The secretary said that what is obviously needed is an accession of members, or, as the other alternative, a reduction in the prizes. He also stated that arrangements had been made with the Crystal Palace Company that the annual exhibition would take place on Friday and Saturday, September 6 and 7. The adoption of the report and balance-sheet was then carried. The Rev. Charles Fellowes was re-elected president, also the vice-presidents.

Some names were removed from the committee and some additions made. Mr. T. W. Girdlestone was unanimously re-elected hon. secretary and Mr. E. Mawley hon. treasurer. The list of

Cactus Dahlias given in the schedule of prizes was revised by the elimination of Baron Schroeder, Cannell's Favourite, Chancellor, Duke of Clarence, Josephine, Lady Skelmersdale, Lancelot, Marchioness of Bute, Panthea, Princess Christian, St. Catherine and Sir Roger, as not representing the advanced Cactus character, and the following newer varieties were added to the list, viz., Major Haskins, Harmony, Mrs. Barnes, Henry Depraesle, Irene Cannell, Mrs. H. Cannell, Mrs. F. Fell, Gloriosa and Earl of Pembroke. Some reductions in the prize money were made in a few of the classes with a view of economising expenditure. It was resolved that for the future no certificate of merit should be given to a Cactus Dahlia unless exhibited in such a manner as to show length of stem as some guide to the habit of growth. Some special prizes offered by Messrs. Dobbie and Co., Florists, Rothsay, for single Cactus Dahlias were accepted. The proceedings closed with cordial votes of thanks to the hon. treasurer and hon. secretary, and to the chairman for presiding.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening last the general committee of this society held a meeting at Anderson's Hotel, Fleet Street, Mr. T. W. Sanders being in the chair. The secretary read amongst other correspondence a letter from Sir Edwin Saunders, thanking the society for again electing him as president. A resolution was then carried to the following effect: "That in order to mark the high esteem in which Mr. R. Ballantine, the late chairman of the general committee, is held, a testimonial suitably engrossed on vellum be presented to him on some future occasion." The report of the schedule sub-committee concerning certain special prizes was then presented, and those from Mr. J. Wills, Mr. W. Wells, Messrs. B. S. Williams and Son, Messrs. Sutton and Sons, and Mr. W. J. Godfrey were accepted. A copy of the catalogue recently published by Mons. O. de Meulenaere was then presented by the secretary, who called attention to its merits as a valuable work of reference in Chrysanthemum literature. It was resolved that the compiler be awarded the society's silver medal in recognition of his work. It was announced that the roll of membership at the present time consisted of 79 Fellows, 508 ordinary members, 27 foreign members, and 114 affiliated societies, an announcement that was received with much interest. One third of the floral committee retiring necessitated an election. The following was the result: Messrs. C. E. Shea, W. H. Lees, J. Wright, D. B. Crane, J. W. Moorman, and E. S. Addison. The election of chairman of that body resulted in Mr. George Gordon being appointed.

The secretary then announced the dates fixed for the meetings of the general committee, viz.: August 26, September 30, October 28, November 18, December 9, 1895, and January 10, 1896. The floral committee will meet on September 3 and 25, October 8, 23, and 30, November 11, 20, and 27, and December 3 and 11.

A report from the Jubilee sub-committee was next presented, in which it was stated that in order to celebrate the fiftieth year of the society's existence a special four days' show should be held, and a new medal struck to commemorate the event. It is proposed to institute some special classes in the schedule, the chief of which are a class for twenty-four Japanese blooms, distinct, with £20 and a gold medal for the first prize, £15 and a silver-gilt medal second, £10 and a silver medal third, and £5 and a bronze medal for the fourth prize. A similar class with the same prizes was recommended for twenty-four incurved blooms. A class for twenty-four single-flowered varieties is proposed, and also prizes for a collection of cut Chrysanthemums, old varieties grown previous to or at the time of the formation of the society. A banquet and conference will also be held, and a liberal donation towards the funds of the society from the Royal Aquarium Society has been promised. The catalogue revision committee was elected, the members being Messrs Harman

Payne, A. Taylor, H. J. Jones, Lees, and Crane. After the election of several new members, the Barnet and District Chrysanthemum Society and the Colechester Rose, &c., Society were admitted in affiliation.

On the motion of Mr. J. W. Moorman, a hearty vote of thanks was accorded to the editor of the new year-book and to the contributors for their work in connection with the book. It was resolved that Mr. Dean in future receive the sum of £75 per annum for clerical assistance instead of £50, as heretofore.

#### NOTES OF THE WEEK.

**Colchicum montanum**, now flowering freely at Long Ditton, is one of the spring-blooming species, the flowers freely produced in perfect clusters, and varying in colour from pale blush to rose.

**Primula denticulata alba**.—This is a nice form of an old garden favourite, and a fine pan of it was staged at the Crystal Palace by Mr. Ware. Its leaves are of a lighter green than those of the type, but the flower-spike is equally stout, erect, and crowded with blossoms.

**Saintpaulia ionantha**.—An error has crept into your note on this in a recent number of THE GARDEN (p. 133). This was not shown at Ghent or anywhere else by M. Linden, of Brussels, who had nothing to do with the introduction of the plant, but by Mons. H. Wendland, director of the garden at Herrenhausen, Hanover.—ED. ANDRÉ.

**Tulipa violacea**.—This new species, now flowering at Long Ditton, will be welcomed for its earliness, as it is in advance of *T. biflora*, hitherto the earliest flowering species. Its name is not exactly expressive of its colour, which is a deep, but beautiful magenta-red, the flower long-petalled and handsome, borne on a stalk about 8 inches in length.

**Calypso borealis**.—This rare and pretty little hardy Orchid appeared in Mr. Ware's group of plants at the Palace show. It is a small plant, a native of American mountain bogs, with a tiny heart-shaped leaf. The flower, like a miniature *Cypripedium*, but with an open pouch, is poised on a slender arching stem about 4 inches in height and of a rosy-purple colour.

**Iris reticulata** is now to be had in several very fine forms, and, unlike some of the early Irises, it is so easily grown that it ought to be very popular. At the Crystal Palace, in addition to the type itself, a variety called *purpurea* was quite distinct, its flowers of a uniform deep dark purple colour. The variety known as *Krelagei* is also very fine, the colour being quite different from that of either of the preceding.

**The Carpathian Snowflake**.—This form of the spring Snowflake is quite true to the distinction that was claimed for it, viz., the production of two flowers on a stalk. At the Crystal Palace show Mr. Ware showed a pot of it containing many bulbs, and all but one or two of the flower scapes had two large perfect flowers. The stain of colour on the tips of the petals is much greener in the flowers of this form than in those of the type itself.

**Arum sanctum and A. Eggeri**.—These two Arums were both shown by Mr. Ware, of Tottenham, at the Crystal Palace on March 17. The former is now becoming better known since the plate of it was published in THE GARDEN of October 14, 1893. *A. Eggeri* may possibly be a variety of the preceding, but in the colour of its spathe it is quite distinct—a rich velvet crimson-purple, chequered with markings of a darker purple hue.

**Skimmia Foremani**.—I saw this shrub at a show a few years ago, and was much struck by its appearance and the number of berries it bore. I bought two plants, and have never yet succeeded in getting them to fruit, although they have

flowered well. I have been told that it is necessary to fertilise the blooms from the *Skimmia japonica*, while another grower says this is not needful. I shall be glad of advice from your readers as to how I may best ensure a crop of berries.—H. WORTHINGTON, *Feniton, Devon.*

**Crocus Imperati and C. biflorus.**—There are so many varieties of the early spring Crocuses in cultivation, forms of *C. aureus* and *C. vernus*, that people are apt to overlook the numbers of other lovely species, and among them the two here mentioned. Both of these are now lovely in the grass. *C. Imperati* is specially beautiful when nestling in grass, the flowers a clear pure shade of rosy lilac. *C. biflorus*, or the Cloth of Silver Crocus, is lovely, the delicate shades varying somewhat from white to the palest lavender.

**Arbutus Menziesi.**—This noble tree is very abundant here on Vancouver Island. I have found it growing from the edge of the salt water to the very top of the mountains (different from what a correspondent stated in a back number of THE GARDEN). I have always found it growing in a dry situation. It seems to prefer a gravel soil, often among rocks. I know one mountain that is nearly covered with it. All the plants are bushes that have sprung up from the roots of old trees that were destroyed by fire a number of years ago. I have a very fine specimen growing at the top end of my nursery on a dry gravel ridge. This tree is about 20 feet high. The grouse and wild pigeons eat the berries.—G. A. KNIGHT, *Mount Tolmie Nursery, Victoria, B.C.*

**Winter-flowering Begonias at Forest Hill.**—For greenhouse decoration these Begonias are very effective, and are equally useful for cutting. Amongst those especially noteworthy at the Forest Hill Nurseries at the present time are *B. Bruanti elegans*, *B. rosca floribunda*, and the pure white variety. These plants are suspended from the roof in baskets, the long graceful habit of the plants having a very pleasing effect. These Begonias should certainly find more favour, as they can be accommodated in any greenhouse where the temperature does not fall much lower than about 50°. They enjoy a nice light open compost, and when once established will continue to grow and flower profusely as long as the plants are kept in good health. Cuttings should be taken during the months of March and April. By cutting back the old plants nice bushy subjects for the following season can be had, and the cuttings will make nice sized specimens and commence blooming the following autumn.

**Begonia socotrana.**—The island of Socotra, which is the only native home of this species, lies in the Indian Ocean about 120 miles east of Cape Guardafui and to the south of Arabia. It is mountainous, rocky, and arid, and, as Sir J. Hooker observes, one of the least likely places in which a Begonia might be expected to occur. It was here, however, that Prof. Bayley Balfour discovered *B. socotrana*, one of the prettiest, most distinct, and useful additions made to the genus in recent years. It is a tuberous species, and the rounded umbrella-like leaves are borne on erect, hairy petioles 6 inches or more high. The flowers are produced on erect scapes a little taller than the leaves, and each one measures 1½ inches to 2 inches in diameter, and of a soft, pleasing shade of rose. The species requires stove treatment. Going to rest in spring, the plants should be shaken out of the old soil and repotted in August, using a compost of turfy loam and sand with a little leaf soil added. Overwatering in the early stages of growth is to be guarded against. From this species Messrs. Veitch have obtained several hybrids, of which John Heal is perhaps the best. Both it and the species itself have been illustrated by coloured plates in THE GARDEN (see numbers for March 18, 1882, and March 9, 1889).

**The Mourning Iris (Iris Susiana).**—I should be glad of some information as to the growth and cultivation of this Iris. I recollect seeing one root in a 6 inch or 8-inch pot in a florist's window at

Cannes in April. This bore three flowers and was admired by everyone. I have since got good roots from Holland every year, but can make nothing of them. One root did bloom once (one flower) in the open air, but it died away, and subsequent roots have neither flowered nor grown. Yet I hear that this Iris grows and flowers in the Dean of Westminster's garden behind the Houses of Parliament. My experience of growing it in pots has been equally disastrous. I have had roots each year carefully planted in pots, large and small, in autumn. These pots have been put into a cold frame. Some have been left there, some have been put into an airy greenhouse, others into different houses, but always with the same result. The leaves quickly spring up, look most luxuriant until 8 inches or 10 inches high, then, whatever the winter or the temperature, they begin to wither and rot just as they do in the open air. I have tried all kinds of soil in vain. As I grow Tuberoses successfully, I thought (from the similarity of the roots) I could easily grow this Iris, but I am mistaken. Other Irises grow well in my soil, but *I. Susiana* beats me. In fact, I never saw in any garden a specimen of it.—R. D.

**Polygala myrtifolia.**—This is one of the many plants which, although seen occasionally in long-established gardens, belongs rather to a past generation than the present. Like numerous other plants which represented in our greenhouses the marvellous floras of South Africa and Australia, it was grown in considerable quantity fifty years ago, but, like the great proportion of the plants from the same regions, went out of fashion twenty years ago. There are, however, signs that this plant, along with others of the same class, are regaining some of their old popularity. An encouraging sign at any rate is their appearance in the shape of neat dwarf specimens on the benches at the Drill Hall during the spring. This *Polygala* flowers during autumn as well as spring, and a large bush 15 feet high was for several weeks in flower in the temperate house at Kew. The leaves, all though in size and shape resembling those of the Myrtle, have not the same deep glossy green, being paler and glaucous. The flowers are so much like those of the papilionaceous legumes, that most people look upon this *Polygala* as one of the Leguminosae. It belongs, however, to quite a distinct natural order to which this genus gives its name. The petals are of a rich glowing rosy purple, the stamens, also rosy, being produced in a cluster clasped by the petals forming the keel. A cool greenhouse temperature is all that is needed for this plant, which when large enough can be planted in the conservatory border.

**Narcissus triandrus.**—This delicately beautiful *Narcissus*, to which the poetic name of Angels' Tears has been given, is valuable for pots during the early spring. On comparatively long stems the flowers, sometimes two or three on one scape, stand well up from the Rush-like foliage, while the reflexed and flanged perianth, poised like white wings on the pendent nectary, imparts a distinctness of form that renders it unlike that of any other Daffodil. *N. cyclamineus* is the nearest approach in form to *N. triandrus*, but its colour is yellow and the perianth shorter and not so graceful. I collected two years since some bulbs of *N. triandrus* in the west of Spain, where they grow in profusion on the hills in a shallow peaty soil, in which is incorporated a large proportion of granitic detritus. I have seen it stated that this *Narcissus* is a lover of marshy soil, but my observations point to a totally different conclusion. The range of *N. triandrus* was confined entirely to the hills, which in summer must have been baked by the sun. In the lower meadows *N. triandrus* gave place to varieties of *N. Ajax*, while marshy spots were entirely monopolised by *N. Corbularia*. Planted out, *N. triandrus* does not appear to be a success; indeed, the flowers are too fragile to be subjected to an English spring without protection. In a pan or pot, however, under greenhouse culture the plants come into bloom during February and are invariably much admired. One pot containing twelve bulbs produced this year twelve flower-spikes, most of them carrying two blooms

and one of them three. The flowers, although so fairy-like, last well in water.—S. W. F.

**Hardy Water Lilies in the house.**—*Nymphaea Marliacea Chromatella* was in bloom in the Water Lily house here on March 1, and a few days later the Water Lily tank was gay, several varieties of Marliac's Water Lilies being in flower. The plants went to rest as usual, but started growing much earlier than I have known them to do for some years. I generally re-pot the Water Lilies in February, but omitted doing so this spring in the hope of having them flower earlier in the season. I am very satisfied with the results and can see no diminution in the size of the flowers. I grow the plants in large earthenware pans made specially for the purpose and also in tubs, so as to be able to arrange them in the tank, which is from 3½ feet to 5½ feet in depth. The soil I use for potting is marly blue clay, loam and cow manure. I put 6 inches or so of the clay in the bottom of the pans and tubs, and the loam and cow manure mixed at the rate of two of loam to one of cow manure. I believe the use of the blue clay is the principal cause of the Water Lilies growing so vigorously as they do. When repotting the plants the strongest roots are found in the blue clay. There is a 4-inch flow and return hot-water pipe in the tank, but the heat is very seldom turned on. I understand some growers run off the water from their tanks in the winter with the object of resting the Water Lilies. Is it a good plan to do so? Here the object is to have the Water Lilies in flower as early in the season as possible; later on the lakes and ponds in the demesne furnish an ample supply.—J. RYAN, *The Castle Gardens, Castlewellan, Co. Down.*

**Effects of the frost in France.**—M. Ed. André writes to us under date of March 9: "The destruction occasioned by the severe weather in Paris and neighbourhood has been immense, but not so great as during the winter 1890-1891. Evergreen shrubs have suffered greatly, numbers having had their leaves destroyed, although the wood is often sound, with the exception of the young shoots. *Prunus Laurocerasus*, *Viburnum tinus*, *Phillyrea angustifolia* and *media*, *Ligustrum ovalifolium*, *L. sinense*, *Ibota*, *Aucuba japonica*, *Rhamnus alaternus*, and *Choisya ternata* have suffered greatly. *Mahonia aquifolium*, *Phillyrea Vilmoiriana*, and *Prunus caucasica* have stood better. The losses would have been far greater if the frost had begun earlier, when the wood was still unripe, but what caused the greatest harm was the duration of the frost, which continued without cessation for forty-five days. The daily thaw burnt up the leaves of vegetation exposed to the sun; whereas towards the north where there was no thaw plants suffered much less. This I proved as I covered up a certain number of Rhododendrons, and these are in very good condition, while those of the same kinds exposed to the sun and thaw, but uncovered, have been much injured. Independently of the losses occasioned by this exceptional temperature to gardens, one must take into consideration the heavy losses nurserymen and seedsmen will sustain by being unable, from the advanced period of the season, to make many more deliveries before the spring. In Touraine the gardens have suffered much less. The leaves are burnt up and the stems of the young Bamboos are frozen, but the old stems have stood. The ground was not so deeply frozen as in Paris, where it was hardened to the depth of 2 feet, a fact certified by M. Bequerel in the *Jardin des Plantes*. Under the snow and under the grass in the same garden the ground was not frozen to a depth of more than 10 centimetres to 15 centimetres.

**Notes from Almondsbury.**—Two or three really lovely days have made bulbs reappear. Hepaticas are out in places, Snowdrops also. It is painful to contemplate trained shrubs, and, following Mr. Smith's advice, I will only say that here with a zero frost *Carpenteria californica* seems quite safe, also *Olearia Haasti*, all the

Magnolias like *longifolia*, *Watsoni*, also the *Hypericums*, *Spiræas* of all kinds, Tree Pæonies, but nearly all variegated-leaved shrubs look very wretched. *Iris stylosa* seems to me to have suffered terribly. I have a large quantity of it at the foot of a warm wall, and the whole mass looks as if a match should be put to it. It is well known that to burn prairie grass just now will ensure double growth this summer. Has anyone dared to try it on other plants? The fire is so often applied to plants and bulbs in their native countries, that one would like to know if a similar application of fire would do good in England. I have a fine pod of seed on *Iris stylosa alba* crossed with *I. speciosa*; it is in a pot, and takes a long time to ripen. Ought I to cut it off and ripen it artificially? I may say I have ripened seed of this *Iris* in England after a very hot summer, and then I think in the open the seed took six months to ripen. In a pot in the greenhouse one ought to be able to hurry matters. Recently there have been buried in our churchyard two interesting old gardeners: one was gardener at Abbotsford to Sir Walter Scott—Brydon by name—the other, aged 85, helped to plant the earliest Tree Pæonies in Lord Clifden's garden at King's Weston about 1824. These Pæonies are enormous specimens at the present time, and when in bloom are a fine sight. The old man had been a great traveller, and was interesting to talk to. His prize cards were a fine collection. He had some interesting species of Roses which I hope to get named this year.—C. O. MILES.

**Dry versus wet leaves.**—A mistake is frequently made in using wet leaves for filling Cucumber and Melon pits. Such, although heating violently at first, invariably go cold in a very short time, decay speedily following. Dry, newly-harvested leaves are preferable for all purposes, especially when used for supplying bottom-heat for striking cuttings. There ought always to be sufficient heat beneath cuttings to enable them to dry once a day after starting. When wet leaves are used, and the heat suddenly declines, cuttings often remain wet throughout the day, particularly when sun is absent, with the result that wholesale damping and stem-rotting take place. For propagating, also for early Melons and Cucumbers, I prefer to rake up a sufficient quantity in spring of Oak and Beech, taking them straight to the pits or beds rather than using those which were collected in autumn and have lain in a mass in the open.—J. C.

## PUBLIC GARDENS.

**Epping Forest.**—The sum of £3600 has been set aside for the maintenance of the forest for the ensuing year.

**Kew Gardens.**—The First Commissioner of Works has received a communication from the Lord Steward stating that, in accordance with representations made that access to the meadow in front of Kew Palace would greatly improve the arrangements for admitting the public to Kew Gardens, he had recently taken Her Majesty's pleasure on that point, and had been honoured by the Queen's commands to cede to his department for the use of the public the greater part of the meadow referred to. This piece of ground is  $4\frac{1}{2}$  acres in extent, and will also, when thrown open, allow visitors a direct instead of a circuitous access to the finest part of the arboretum.

**A new recreation ground for Clekenwell.**—The Works Committee reported that they had considered the proposal to lay out as a public recreation ground the churchyard attached to St. James's, Pentonville. The opinion of counsel had been taken by the trustees as to the right of the vicar to prohibit the laying out of the ground as an open space, except upon conditions imposed by himself. Counsel's opinion is to the effect that the rights of the vicar are limited if the Consistory

Court will grant the necessary faculty. The Public Gardens Association had, through their secretary, signified their intention of laying out the churchyard as a public garden, at a cost of £500, on the understanding that the Vestry would maintain the ground. They (the committee) recommended that the solicitors to the Vestry be instructed to take the necessary steps to obtain the faculty from the Consistory Court for laying out the ground as an open space in accordance with the above terms.

**Epping Forest.**—The Epping Forest Committee of the Corporation have recently presented their annual report for the past year. It shows that 16 acres of Wanstead Flats have been drained and levelled for football and cricket, as a means of giving work to the unemployed. The forest had suffered much less than usual from fire, and the committee were of opinion that the thinning had in many places checked damage from that cause. Various new bye-laws had been made, making it an offence to throw lighted fuses or matches in the forest, preventing the sale or distribution of intoxicating liquors in the forest by so-called "clubs," preventing the molestation of commoners' cattle and bringing dogs into the forest unless under effective control. When the London, Walthamstow, and Epping Forest Railway was constructed the committee felt sure that it would make the forest more accessible to the people residing in the northern parts of the metropolis. The income of the forest last year was £6148, including £2600 from the Corporation, and the expenses £6610.

**Open spaces.**—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, W., Mr. F. D. Mocatta, vice-chairman, presiding, a grant of £5 5s. from the Leathersellers' Company, and donations of £25, £15 14s., and £10 towards special schemes on hand were announced. Communications were read from the municipalities of Paris and Brussels giving detailed lists of their public open spaces. The opening of Lincoln's Inn Fields and Whitfield's Tabernaec burial ground by the London County Council was reported, the association having taken a prominent part in the efforts made for their acquisition and preservation. It was agreed to place seats in Imperial Institute Road at a cost not exceeding £35; to give seats for Strand-on-the-Green, the Chiswick District Council paying half the cost; to lend some gymnastic apparatus for evening classes at a school in Stepney, at a cost not exceeding £10; to communicate with the Newington Vestry respecting the vacant site in East Street, Walworth; to undertake to provide trees and seats for Petherton Road, N.; and to lay out the disused burial-ground of St. James's, Pentonville Road, as a public garden, if the Clerkenwell Vestry succeeded in securing it and agreed to maintain it as such. The secretary announced that the erection of gymnastic apparatus in the crypt of St. Peter's, Walworth, had been completed, and that the children's playground added to St. Nicholas Garden, Deptford, would soon be ready for the reception of the apparatus which the association recently granted. It was reported that the laying-out of All Hallows Churchyard, London Wall, and the planting of trees in Whitechapel Road, which had been delayed by the frost, would soon be completed. A letter was read from the Mercers' Company declining to allow Arbour Square, E., to be opened to the public. Amongst other matters which engaged the attention of the meeting were the proposed preservation of the site of Clapton Pond and Paddocks and the laying out of Bartholomew Square, E.C., a vacant site in Canning Town, E., the Friends' Graveyard in Long Lane, S.E., and St. Mary's Churchyard, Battersea, S.W.

**Mr. Martin Hope Sutton.**—To very few is it permitted, after an active and successful business career, and a life spent in works of usefulness, social, philanthropic, and religious, to enter the threshold of four score years. An honoured resi-

dent of Reading—Mr. M. H. Sutton—has lived to attain his 80th birthday, the 14th of March, and the pleasurable occasion was on Thursday last duly observed. Mr. Sutton received over 100 letters and telegrams, besides a great number of congratulatory visits from friends in Reading. Addresses were also presented, amongst others, by the Church of England Y.M.C.A., the Reading and District Gardeners' Mutual Improvement Association, and by the chiefs of departments of the Royal Seed Establishment, from which business he retired in 1888, after being head partner for more than fifty years.

**The weather in West Herts.**—The most noteworthy feature of the weather of the past week has been the gradual decline in temperature during the evening and night, and its rapid recovery in the morning after the lowest point had been reached. Several days were very warm for so early in the spring, the readings in shade on two of these reaching 56°, and on another day 58°. On the coldest night the exposed thermometer indicated 11° of frost. Since the beginning of the month the temperature of the ground at 2 feet deep has risen 8°, at 1 foot deep as much as 12°. At the depth of 1 foot the reading is now 44°, which is 4 warmer than the March average for the previous nine years, but 1° colder than at the same time last year. Three days of the week were very sunny, the record of bright sunshine on each occasion exceeding seven hours. *Chionodoxa Lucilia* came first into blossom in my garden on the 19th inst., which is only six days later than its average date of first flowering for the previous seven years, but thirty-three days later than last year.—E. M., *Berkhamsted*.

## OBITUARY.

**Mr. John J. Thomas**, one of the most eminent American pomologists, died at his home in Union Springs, New York, on February 22, aged eighty-five years. Among his works, "The American Fruit Culturist," which was first published fifty years ago, still remains probably the most useful work of its kind. It has been revised many times to keep pace with the advance of pomology in America, and the latest labours of Mr. Thomas were given to the preparation of a new edition, which is to be published in May. Nine volumes of miscellany, entitled "Rural Affairs," which are selections from the *Country Gentleman*, of which he was an associate editor, were prepared by him. Mr. Thomas was a man of great simplicity and sincerity of character, combining sturdy integrity with a rare refinement, gentleness and unflinching charity.

**Royal Horticultural Society.**—At the next meeting of the Royal Horticultural Society, which will be held in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, March 26, Mr. T. H. Crisp will, at 3 p.m., read a paper on "Lifting Large Trees and Shrubs." The vacancy caused on the fruit committee by the lamented death of Mr. Geo. Taber has been filled by Mr. Iggulden's appointment by the council. The vegetable show has now been definitely fixed for September 10 instead of October 15, and will be held at Chiswick Gardens instead of in the Drill Hall, as stated in the society's "arrangements" for the year. The show at the Drill Hall, therefore, on October 15 will be an ordinary fortnightly meeting.

**Names of plants.**—J. W. — Specimen too shrivelled to identify.—*Arthur Dadsell*.—Purple Crown variegated single Tulip.

**The Wild Garden; or, the Naturalisation and Natural Grouping of Hardy Exotic Plants, with a chapter on the Garden of British Wild Flowers.** Fourth edition, with wood engravings from drawings by Alfred Parsons, revised and enlarged. Teny 8vo, linen cloth. Price 12s.; well bound in half morocco, 15s. Through all booksellers.

"This is an Art  
Which does mend Nature; change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare*.

## FLOWER GARDEN.

### THE JAPANESE ANEMONE AND ITS VARIETIES.

THE Japanese Anemone and its two varieties with white and pink flowers are so well known and universally appreciated, that it would be superfluous at the present day to describe and extol them. But as these three original forms of the plant, hitherto so fixed and invariable, have commenced to exhibit some modifications, in that of late years three or four varieties differing from the older types have made their appearance, it seemed desirable to me in describing these new-comers to refer to the origin of their progenitors.

Anemone japonica (Sieb. and Zucc.), discovered in Japan by Thunberg, who took it for an Atragene, was re-discovered by Siebold, who saw it growing in the wild state on the high mountains of the central island, in moist woods, and on the banks of streams. It was at last introduced into Europe in the year 1845 by Fortune, who met with it in China (near Shanghai), and sent plants of it to the Royal Horticultural Society, London. It flowered for the first time in the grounds of this society in 1845, and in the following year Louis van Houtte published a coloured plate of it in the "Flore des Serres et de Jardins de l'Europe." Now everybody knows this perennial plant with downy foliage, branching stems, pinnatisect leaves unequally lobed and with rather narrow segments, and long stalked flowers generally composed of two rows of irregular, narrow, hooded petals of a more or less dark carmine-pink colour.

The origin of Anemone japonica elegans is not so clearly established. According to Decaisne, who made a distinct species of it under the name of *A. elegans*, Dene. (*Revue Horticole*, 1852, p. 41), it has in Japan the same habitat as *A. japonica*. It may be admitted that it was introduced into Europe shortly after *A. japonica*, since before 1850 it was mentioned in nurserymen's catalogues under the name of *A. japonica hybrida*. Ornamentally superior to the type, it is distinguished from it by its more ample foliage, its broader leaflets, its stouter, taller, and more numerous stems, and, lastly, by the form and colour of its flowers. These are of larger size and have from five to nine broad, rounded petals of a handsome, perfectly uniform light pinkish-lilac colour, and cottony on the under surface. These differences, although very important from a horticultural point of view, do not appear to be sufficient to warrant the formation of a distinct species, and notwithstanding the authority of Decaisne, we shall regard Anemone elegans as simply a variety of *A. japonica*.

From the facility with which it can be grown and propagated, this fine plant very soon became widely cultivated, and, amongst others, M. Jobert, a banker at Verdun (Meuse), was supplied with it from the establishment of Messrs. Thibaut and Keteleer, which was then located at Paris. In M. Jobert's garden one of these plants of *A. japonica elegans* happened to "sport," a shoot of it producing perfectly white flowers. When this variety was fixed, four

nurserymen received each a plant of it at the same time, and one of these nurserymen, M. Victor Lemoine, of Nancy, was the first to send it out in the early part of the year 1863. Such was the origin of Anemone japonica alba, which is also known as *A. japonica Honorine Jobert*, and which, with the exception of its white flowers, is identical in every respect with *A. japonica elegans*. It has now spread all over the world and is multiplied in millions, having almost entirely superseded the two other forms which were in cultivation before it appeared.

Twenty-five years passed away before any of the three original Japanese Anemones produced the slightest variation from the existing forms. This was owing to the circumstance that, as M. Van Houtte mentioned in 1846, "the seeds of this plant rarely become fully developed and fertile, even in its native country," and experience has shown that in Europe this never occurs at all. We have never heard of a single plant of these Anemones that was raised from seed, and it is amongst seedling plants that varieties are chiefly to be found.

To an accidental crossing, however, the origin of a new American variety which was sent out under the name of *A. japonica Whirlwind* by Messrs. James Vick and Sons, of Rochester, N.Y., U.S.A., was at first attributed. This plant is identical in foliage with the typical Anemone japonica and grows nearly as tall. It forms low, compact tufts of foliage and numerous firm flower-stems terminating in semi-double, cream-coloured flowers with greenish shades on the back of the petals. The general appearance of the plant differs essentially from that of *A. Honorine Jobert*, which is of taller growth and more graceful habit, bears its flowers at various heights on the plant, and has more slender peduncles. The American variety, on the other hand, bears all of its rather stiff-looking inflorescence at the same level. In their catalogue for the year 1887 Messrs. Vick described this variety as "a new double white Anemone, the result of a cross effected by some bee carrying the pollen between the single white Anemone and the semi-double pink variety." To anyone who is aware of the negative character of the Japanese Anemones in the matter of self-fertilisation and hybridisation, and of the difficulty of obtaining, in a climate more rigorous than ours, any naturally-ripened seed, the explanation of Messrs. Vick appears rather conjectural, and it is, moreover, so vague that it does not state which plant was the seed parent. Until we are better informed on the subject we shall regard *A. japonica Whirlwind* as a fresh sport, produced either by *A. japonica alba* or, as we think is more probable, by a plant of the typical Anemone japonica. Another reason which prevents us from regarding this variety as a seedling one is that in our grounds it has shown itself to be absolutely sterile, notwithstanding all our attempts to fertilise it artificially; whereas plants which are produced by hybridisation are generally very fertile.

When a plant which for the space of nearly fifty years has shown itself to be sterile and absolutely refractory against every attempt to fertilise it, at length, by the merest chance, produces two or three fertile seeds, there occurs a break in the history of the plant, which, however insignificant it may appear, is really of the highest importance, since it may prove to be the originating cause of extensive modifications. Such an event took place a few years since in Ireland and is recorded in THE GARDEN for 1892 by Mr. A. Campbell, gardener to Lady Ardilaun, Cong, Co. Galway. Mr. Campbell says: "Having had numerous inquiries about my new

Anemone, I beg to state that six years ago I observed a head of seed on a plant of *A. japonica alba*. This had an enlargement upon one side like a wart. This I sowed when ripe and got three seedlings from it. One of these I found much finer than the other two. From this plant the stock has been raised." This new variety was named *A. japonica Lady Ardilaun* and soon came into general cultivation on the Continent. It is distinguished from *A. japonica Honorine Jobert* by its taller growth (about 5 feet high), its thicker stems and peduncles, the width of its large, coriaceous leaves which are of a brilliant green colour—and especially by the greater size of its flowers, the petals of which are broad, firm and of a pure white colour. It is a noticeable circumstance that the whiteness of the flowers, which in the first case was the result of a sport, was here a characteristic of a seedling variety also.

A distinguishing feature of the Lady Ardilaun Anemone is that of producing seed, which ripens readily in the open air in a climate more favourable than ours. By artificially fertilising this plant we have obtained a series of seedlings which are commencing to show the greatest diversity of variation in habit, size of flower, doubleness and also in colouring. One of the first of these seedlings, which we sent out in March, 1894, is named Anemone japonica alba semi duplex, and was offered for sale at the same time as the American Anemone Whirlwind, from which it is distinguished by its different habit, more ample and livelier-coloured foliage and flowers containing from ten to twenty broad, round, pure white petals.

Another variety which we intend to advertise in the spring of the present year (1895) was exhibited by us to the Horticultural Society of Nancy last November under the name of *A. japonica Coupe d'Argent*. The leaves of this are large, like those of *A. Lady Ardilaun*, and also firm (nearly coriaceous) and of a quite lustrous and brilliant green colour. The stems, which are of the thickness of a lead pencil, are very perpendicular in growth, each bearing numerous flowers which stand perfectly erect on firm foot-stalks. The flowers, which are individually about  $3\frac{1}{4}$  inches in diameter, are formed of three or four rows of more or less undulated and hooded petals looking like little cups. From thirty-five to sixty of these small petals have been counted in a single flower. The colour of the flowers is creamy-white passing into pure white. Flowers which open after October 15 have a slight pinkish tint. The plant is, on the whole, of large dimensions; its perfectly erect habit of growth is quite distinct from that of *A. Honorine Jobert*, and its flowering-stems grow to twice the height of those of the variety Whirlwind.

Other seedlings which we have now under observation lead us to expect that the day is not very far off when the gardening world will become all the richer in possessing double-flowered Japanese Anemones in great variety of colour. EMILE LEMOINE.

Nancy.

**Cordyline australis purpurea.**—This is a very distinct form of the popular Cordyline australis, which is perhaps better known by the generic name of *Dracena*. When plants of the normal type are raised in quantity from seed there is frequently a considerable amount of variation to be found among them, the plants differing from each other in the width and number of the leaves, in their texture, and other particulars, but, generally speaking, not in the colour of the foliage. The above named variety, however, has the leaves of a uniform bronzy brown tint, much after the manner of that form of the New Zealand Flax

(*Phormium tenax*) to which the varietal name of *atro-purpurea* has been applied. This bronzy tinted *Cordylina* is well worth growing for the sake of variety, but at the same time it is not so attractive as the type, and far less showy than the variegated forms, which are very effective when associated with other plants. The ordinary form of *Cordylina australis* is increased in considerable numbers by seeds which are readily obtainable. Such a mode of propagation is not available for varieties like this, as the plants have not attained flowering size, but even if they were to produce seeds it is not at all probable that the prominent characteristics of the individual would be transmitted to the progeny.—H. P.

#### NOTES ON HARDY PLANTS.

**Bog plants.**—In reply to the interesting letter of Mr. F. W. Harmer (pp. 109-10), I am not yet in any better position than a few years ago with regard to the smoke from great ironworks on the one hand and the smoke of Leeds on the other. Still, I do not think that my position for gardening is absolutely bad. During the last twenty years I have come to believe that with care one may succeed where the surroundings are not absolutely or directly injurious to the plants. If Mr. Harmer will kindly excuse me for saying so, I feel certain that were I to change to where he would put me—nearer the river—I should be very much worse off, even with bog plants, and hundreds of other things would then be impossible. The water of the Aire is yet, and likely for some time to be, almost like ink, and a dense fog frequently hangs over the river. Even at my short distance I can rejoice in immunity from these fogs. Moreover, I take it, that to be on slightly rising ground on deep sandstone, with further rising ground in the rear, is not bad for a garden from the moisture point of view.

**Tropæolum speciosum.**—I scarcely wished to convey the idea to anyone that this plant disliked wet, though I should never think of growing it as a bog plant. I rather sought to convey the idea that whilst a naturally deep-rooting species is being established, it should be protected from wet and cold to help it until it took its place naturally in deep soil.

**Primula Sieboldi.**—I quite agree with Mr. Harmer's remarks, and I was struck by the statement of "A. D." that this did not like moisture. My experience is that, without giving it in the open air both a moist situation and a soil retentive of moisture as a safeguard against a dry spring or summer, none of the *Primula crotosoides* group ever do any good. I like to use it especially as an edging plant for a flat border where a main walk catches a number of other small walks at right angles from sloping ground. Such walks act as feeders during summer showers to the cross-walk, and give in a degree a sort of semi-bog condition, and just the place for such gay, but humble flowers as this *Primula* in all its varieties, *Calthas*, *Galax*, *Gentians*, and moisture-loving bulbs.

**Sunflowers.**—The noble picture so finely presented to us on p. 109, and the wonderful account by Miss Willmott, who photographed the specimen portrayed, are almost enough to make us discontented with our climate, but though we have to be content with far less gorgeous results, we may now and then gather a hint from what in such cases as the present can only be described as phenomenal results. We see by Miss Willmott's note that the results were far better in the case of the self-sown plants, and though the species specially referred to by Miss Willmott is but one of the annual varieties, it doubtless points to the desirability of dealing with hardy plants in the autumn as regards either seed-raising or the planting of roots of the perennial species, and I think were the root habit of the species studied it would be seen that, at least in the case of annuals, the capabilities of the plants could hardly have full scope when raised in spring of the year intended for flowering. Of course, as regards the peren-

nial plants generally dealt with in the form of roots, a spring transplantation might not be so well as an autumnal one, but the plant would grow out of its drawback by the following year. As a matter of fact I have found the transplanting of the perennial species give better results when done immediately after the foliage began to turn brown in late summer. Usually we find that the late-flowering composites are as well left for spring planting as in the case of *Michaelmas Daisies*, but I think somehow it is different with the *Sunflowers*; and what I should consider to further confirm this, anyone may prove for himself, the great amount of root-acton that takes place in late summer after root-division and replanting. This surely means something in the way of extra vigour for the following year.

**Rosa Leschenaultiana.**—I believe this is as difficult to procure as it is beautiful. I have long been seeking both at home and abroad for a couple of specimens or even material in the form of cuttings, in the hope of trying its capabilities both here and in a noted south of England garden. I cannot but think that others would be interested to know where this elegant *Rose* of the *sempervirens* group could be had. Evidently it is not in commerce, and, from what I hear of it, it is a *Rose* beyond all praise.

**Gentiana alpina.**—I find this name is being much more employed than formerly, which I fear many will find inconvenient, not that it is not a well authorised one, but because there are perhaps too many authorities for it—five, I think. From a gardener's point of view the name is a poor one for a *Gentian*, as nearly all the species are alpine, and the gardener is not to be reasonably expected to always inquire into the meaning of one name as applied to various plants. This is, of course, the real difficulty of several authors giving one name for different plants. According to Grisebach's treatise of the *gentianaecous* species, *alpina* is referable to three species, viz. *gelida* (M. B.), *aeaulis* (L.), and *verna* (L.). *G. alpina verna* (Tournef.) is synonymous with *verna* (L.), *G. alpina latifolia* (Bauh.) is synonymous with *aeaulis* (L.), and *alpina* (Vill.) is referred to the same, but as a sub-variety, i.e., through *angustifolia* (Vill.). *G. alpina* (Adams) is synonymous with *gelida* (M. B. or Hook.) and also with *armena* (Tournef.). This (*gelida*) is perhaps the rarest of all *Gentians*, as it is not known where a single specimen, dead or alive, exists excepting in our national herbarium. I can scarcely believe that all this nomenclature will seem perfectly clear without a little further examination, but I give these facts as an instance of plant nomenclature, not so much for their intelligibility at a first glance as to show how error may easily occur when different authorities employ one plant name, but which by the respective authors may refer to different plants. It may be useful also as showing that in some cases of old and large genera we should by some means, as that of giving the author for the plant intended, seek to make our intentions clear.

**Aciphylla squarrosa.**—This beautiful umbellifer, known in its native country (New Zealand) as Bayonet Grass or Bayonet Plant, is, I believe, widely doubted as a hardy plant. I am not so sure that it is wanting in hardiness, neither the kind known as *A. Colensoi*, be it a species or a variety of the present. However, my specimen seems to be in perfect order, having endured 31° of frost. Of course there is a deal to be said for environment. I do not think that in the lower part of the garden, where there is a little more shade and wet and a soil somewhat colder, quite as satisfactory results would have come about; indeed I have noted carefully that unless the plants are grown in the fullest exposure and with their collars dry, they are liable to make a growth too succulent and tender, and all the worse because they continue to make late growth. I have noticed that the peculiar forked grass-like foliage, or hard ribbed leaves with their steel-like points, are extremely susceptible to anything near them obstructing the light. Young plants against a wall become drawn badly in a day or

two, throwing themselves out of their rounded symmetrical form into the oblique. This to my mind indicates such influence of direct light, that I think it reasonable that the requirements of the plant for the openest exposure amount to an essential in its culture. I do not know what other people's experience may have been with this curious genus as regards transplanting, but I have never yet succeeded with a plant in the open ground that had been transplanted after the age of two or three years at most, and when I speak of age I mean the age of a plant from seed, which is by far the best means of propagation. By-the-by, seed of late has been somewhat scarce. I suppose it is generally known that some plants are wholly male and others wholly female. What a grand effect is to be produced by a mixed group of the *Aciphyllas* as I saw them many years ago at the Edinburgh Royal Gardens, and it was at that time I observed the marked difference in the sexes.

**Epigæa repens.**—Corresponding with my friend Mr. Gerard, of New York, he employs a few sentences of such practical worth in reference to establishing this plant, and having special reference to what I said a little time ago about seedlings, that I think they cannot fail to be of general interest. He says, "I notice your note on *Epigæa*. That is a case in point as to growing our native plants. It would scarcely pay any tradesman to grow them (the seedlings) on, though it is the only practical way to furnish plants likely to live. You can go into the woods and pick up big plants much faster than you can find seedlings, and the ordinary receiver of large plants would think he was getting treasures, though none of them lived. The plant grows easily enough if properly established, and I have seen it on rocks by the wayside in full sun." J. Wood.

Woodville, Kirkstall.

**Sweet Peas.**—"Selwood" in his article on Sweet Peas (p. 130) says "Curiously enough, the growth first formed by Peas raised in pots rarely reaches a flowering height; it is the growths that spring up from the base that do such good service." Now this does not at all agree with my experience in growing Sweet Peas. I always sow the seed in pots and plant out from those 5½ inches in diameter, giving the plants one shift from the smaller pots they are sown in. Last year the first-formed shoots grew 8 feet high; in some instances the side growths from these measured 5 feet. The main point about Sweet Pea growth is to sow thinly and keep the plants growing freely by liberal water supplies during dry weather and freedom from seed pods.—E. M.

**Marie Louise Violets.**—I send you a sample of *Violets* grown here, and would value your opinion on them. One flower measured at hazard I found 1½ inches across. The *Violets* are all grown from crowns, and all runners are cut off as soon as seen. The young plants are put out in the full sun and have it on them all day long, and in dry weather they are well watered. At the beginning of September they are moved into a frame. The frame has brick sides raised 2 feet in front, 3 feet behind, and is filled in with flints and rubbish to within a foot of the glass. The bed is composed of nothing but leaf-mould, which is collected from under the Beech trees and screened. The plants are put in so that they touch the glass, and shut up at sunset. Free ventilation is given when there is no frost, but as soon as the days get short and cold the lights are put on before sunset so as to get a little warmth. During frost the frame is covered, and kept covered till it has gone, but opened to get flowers as good as those during sunshine. The soil here is light, and of course being on the Plain is very chalky. The wild *Violet* grows in the fields here, and covers the banks with purple, giving out a strong sweet scent, so no wonder cultivated *Violets* do well with care. As I write, my frame, 24 feet by 6 feet, is one mass of flower.—ARTHUR NEWALL, *Wilsford House, Salisbury.*

\* \* \* The finest flowers of this handsome *Violet* we have seen.—ED.

## CHRYSANTHEMUMS.

JAPANESE CHRYSANTHEMUM  
DUCHESS OF YORK.

DUCHESS OF YORK must be regarded as the first Scotch seedling Chrysanthemum ever raised. It is a matter of general observation amongst lovers of this popular flower that wherever it is grown with any degree of success for exhibition, it follows as an inevitable result that the growers sooner or later gravitate towards the more interesting phase of culture, viz., seedling-raising. And so it has been with our

of merit. It has also been awarded a silver medal at Edinburgh and a silver medal and a certificate at Glasgow. In this respect the Scotch variety seems to rival even the equally celebrated American novelty Philadelphia, which came out the same season.

The reputation of Duchess of York may therefore be considered as established, especially when it is added that it is now figured for the fifth time in horticultural literature. Mr. H. J. Jones, of the Ryecroft Nursery, Lewisham, was not slow to recognise its value as an exhibition flower, and the stock, therefore, passed into his hands for distribution. Little can of course be said as yet about its cultivation in the south, for I believe all the blooms that gained awards

*Chrysanthemum Duchess of York. From a photograph sent by Mr. H. J. Jones, Lewisham.*

Scotch friends. Mr. Laird has shown in his article, "The Edinburgh Chrysanthemum Shows," which appears in the recently-published Chrysanthemum year-book, what a firm footing the flower has obtained in Scotland. The difficulties of ripening seed even so far north as Edinburgh must be great, and perhaps from a pecuniary point of view almost impossible, but Mr. J. Carruthers, of Corstorphine, has obtained seed from a friend resident in Japan which, having been sown, has resulted in the production of a new variety which will undoubtedly make a mark in the world. Blooms of this variety were staged in splendid condition at the floral meeting of the N.C.S. as early as October 10 last year, when it was awarded a first-class certificate. It was also exhibited at a floral meeting of the R.H.S. on November 27 and there received an award

were grown by the raiser. My own notes of the variety when it was first shown only apply to the blooms, and I therefore extract from Mr. Jones' catalogue the following details, which are more complete: "The colour of the bloom is soft light yellow; it is of extra size, most massive and graceful in form; the florets, which are long and prettily cut, droop and build up a flower of a true Japanese character. The plant grows about 5 feet high without topping, and the handsome foliage is retained to the last. Good from any buds, but those secured near August 20 will produce the more perfect specimens. Use 10-inch pots and adopt high feeding."

The illustration accompanying these notes gives a very faithful idea of the flower as exhibited and has been much reduced from the original photograph. There is no doubt but that next season's cultivation will place this

first Scotch seedling very high in the list of popular show Chrysanthemums.

C. HARMAN-PAYNE.

## CHRYSANTHEMUM W. H. LINCOLN.

I WILL try and satisfy "S. W. F." as to my reasons for using the words "outraged Nature" in my note (p. 128), as the term he substitutes does not meet the case. The outrage, or action, I had in view was the lifting of a plant from the open ground in October, and the consequent mutilation of roots combined with the subsequent altered conditions in which such plants generally have to exist for a time, viz., under shade and in a closer atmosphere than that to which they have been accustomed. Such treatment is certain to give a severe check at a time when the resources of the plant are being severely taxed by the formation or swelling of the buds, and the deprivation of light is both unnatural and a hindrance to the proper development of the flowers. Most growers recognise the fact that the period directly subsequent to the bringing of the plants under glass is a critical time, even with plants which have been grown in pots throughout the season and which need not be kept in a close atmosphere or shaded. We need go no further than to "S. W. F.'s" plant to see the effect of these altered conditions, for some of the buds on it refused to swell, and others produced small and badly shaped blooms. If Nature did not intend these buds to develop, will "S. W. F." kindly tell us the reason? If she did, then she was in some way outraged. We know that plants are grown in this way in large numbers every year, and that they produce fairly good blooms which are probably saleable, but such blooms will not compare well with those grown under other and, as I think, better conditions. I am no admirer of huge-flowered Chrysanthemums, but I must say that blooms of the variety in question which only average 3½ in. in diameter are undeveloped, and would scarcely show their true character. I still think that "S. W. F.'s" example bears out in a measure my remark that only one flower should be allowed to remain on each shoot. I must own that I am not yet convinced that blooms sold at 1s. per dozen, even without the pots, can be remunerative, though they may occasionally be sold at that or even at a lower price. Flowers and fruit, too, have sometimes, unfortunately for the grower, to be sold for less than the cost of growing. But when one is told that such blooms and at such a price would prove "a veritable gold mine" to the grower, it strikes one that the term is used more as an euphemism than for its generally recognised meaning.—J. C. TALLACK.

—I see that in my note on the above Chrysanthemum (p. 161) a misprint occurs. I wrote "Although no disbudding had been practised, the individual flowers were of good size, as, owing to the fact of the sap having been monopolised by the centre bloom on each shoot, none of the side buds developed." The word "some" having been used for "none," the sentence contradicts the context, and confuses the point of my contention.—S. W. F.

## DEPTH IN CHRYSANTHEMUM FLOWERS.

I AM quite willing to own that, as Mr. Douglas points out (p. 127), I was writing here in expressing an opinion that extreme depth did not necessarily mean added beauty to Chrysanthemum flowers. I do not, however, agree that "all the best judges are agreed in giving good points for depth." It does not follow that a man shall be a judge of what is most beautiful because he is, or has been, a successful cultivator of this or any other class of plant. The standards set up by judges of show flowers, whether Chrysanthemums, Auriculas, Carnations, or what not, are narrow, and no one knows this better than does Mr. Douglas, as he has plainly shown in recent articles.

The main cause of the popularity of Japanese Chrysanthemums is the graceful and artistic

arrangement of the petals, but this grace of form is gradually being lost in the struggle for depth of bloom, which cannot help but make the flowers appear lumpy. Already many of the most striking varieties have had to be put by as useless for showing because of the want of this very lumpiness. I am far from blaming those who are called upon to act as judges. A standard of some kind they must have, and the first thing of which a grower thinks is the skill required in the production of the flowers, and I grant that a skilful and strict attention to details is needed to add depth to the flowers. But many of the newer kinds that are exhibited have to me but little beauty of form to recommend them, and their only claim to the position is that the flowers can be had of great depth. I have before me a catalogue in which the proportions of some of the newer kinds are given. I find one described as neat and 6 inches in diameter by 5 inches deep. Another monster is 9 inches across and the same in depth. I grew last year a variety sent to me as Marquis de Paris. I will not vouch for the name, and cannot now say to what depth it had attained when finished, but I will say that it was out of all due proportion to the diameter. The flowers were remarkable certainly, but remarkably ugly, I thought. And it is not only in cut blooms that this craze for depth obtains. One would think that for groups of plants grace of form would have some weight, if combined with a fair amount of skill in culture and arrangement in grouping; but in one representative show last year the first prize group contained many flowers which had been forced into great depth at the cost of loss of character and beauty. There was not time to dress the flowers, consequently each had here and there tufts of petals which had pushed themselves considerably in advance of their neighbours on the same flower, thus giving the whole group a rough and inelegant appearance. But what were the judges to do? The depth was there and the prize went there too. But when writing my note on Chrysanthemums for the new year I was not thinking of show blooms, and even the wisdom of "the best judges" must not be allowed to force itself on the grower of flowers for decoration, or some of our most beautiful varieties would soon be lost to us.

J. C. TALLACK.

#### SPECIMEN TRAINED CHRYSANTHEMUMS.

ALTHOUGH not receiving so much encouragement at autumn exhibitions as formerly, trained plants have still their admirers. Now is a good time to make a selection of suitable plants for the present year's flowering. Some varieties succeed much better than others under this form of culture. I have drawn up a list of varieties that are especially adapted for this mode of culture. As the Japanese and reflexed sections are better adapted to this form of culture than are the Anemone-flowered or the strictly incurved varieties, I purpose selecting kinds mainly from these sections, making an exception in favour of the small-flowered incurved trio Mrs. G. Rundle, G. Glenny, and Mrs. Dixon. No better specimens are ever grown than those of this trio. Not only are they of free growth, flower profusely, but bear also neatly formed blooms of the true incurved or Chinese form. Although instances occur where some of the largest flowering varieties in the Japanese section are utilised with the best results as specimen plants, they cannot be so much depended on as the small or medium-flowered examples. Of Japanese the following varieties are, owing to their habit of growth and freedom of flowering, deserving of cultivation as trained specimens: Maiden's Blush, creamy white, tinted blush; William Stevens, quite one of the best, bronze-red; Peter the Great, lemon-yellow; William Tucker, rosy-purple; Stanstead Surprise, rose-lilac, shaded gold; Sunflower, rich golden yellow; Vivand Morel, rosy-pink; Roseum superbum, rosy-lilac, shaded buff; Val d'Andorre, orange-red; Triomphe du Nord, bronze-crimson; Margot, rosy-salmon; La Triompheante, white, suffused with delicate purplish-rose; Elaine, pure

white; Mlle. Lacroix, white; Amy Furze, blush-rose with lilac tinge; William Robinson, orange tinted rose; Bouquet Fait, soft rose-pink; and Bertier Rendatler, orange, shaded with yellow and red. Many of the varieties in the reflexed section are well adapted for this mode of culture on account of their free-flowering habit, less tendency to develop irregularly formed flowers, and their adaptability to training, owing to their somewhat natural weeping habit of growth. The Christine family produces no less than five varieties, pink, peach, golden, blush, and the white form generally known as Mrs. Forsyth. Dean Sharpe, rich purple-magenta; Elsie, pale canary-yellow, passing almost to white; Chevalier Damage, deep golden yellow; King of Crimsons, rich sanguineous crimson; Phidias, rose-blush; Wm. Earley, bright rose-purple; and William Neville, deep orange, suffused with red in the centre.

Of pompons we have many deserving varieties; their natural free-flowering habit combined with bushy growth renders them quite suited to this form of culture. Marie Stuart, Anemone pompon, pale lilac guard florets, sulphur yellow centre; St. Michael, rich golden yellow; Black Douglas, rich dark crimson; Mr. Astie, also Anemone pompon, golden-yellow self; Mlle. Marthe, white, shapely blossoms; President, dark rosy-crimson; Marabout, white florets, fimbriated, and the three varieties of Cedo Nulli are the best in this section.

E. MOLYNEUX.

**Chrysanthemum Mrs. F. Thomson.**—I have been surprised not to see included in some of the comprehensive lists of late-blooming Chrysanthemums lately given in THE GARDEN the above variety, as here for several seasons it has proved the very latest of late sorts, and even now (February 29) we have several plants carrying nice blooms—terminals—freely disbudded, consequently are of good size, and the colour—a pretty silvery pink deepening towards the centre—is very attractive, more so than late than earlier. It is a robust grower, carrying abundant foliage which is not addicted to mildew, and although not a variety of recent introduction, I think it may safely and profitably be included in any collection of latest blooming kinds.—J. R.

#### CHRYSANTHEMUM NOTES.

PERSONS who failed to remove their cuttings from outside frames will have cause to remember the year 1895. In some localities where the plan of cool treatment finds favour we hear of almost entire collections being ruined, and it really seems advisable to adopt a safer method of striking the cuttings in all cases. In some past seasons very satisfactory results have followed striking Chrysanthemums in cold frames, but whether this plant is becoming less hardy through the high culture of later days I cannot say. The fact, however, remains that they will not stand frost with impunity. I well remember a large piece of ground in a nursery planted with Chrysanthemums for stock. They grew and flowered, were potted, again planted like hardy border plants, and year after year gave a rich display. The other day I saw some tufts of early-flowering sorts near a wall, which were perfectly safe just underneath the surface, and yet a few yards away in the open roots of Mue. Desgrange were quite dead, these being made secure, it was thought, by placing a mound of leaf-mould over each root. But this last is not one of the hardiest sorts, and if left in the open all the winter it is wise to have other plants coming on under glass to replace them should severe weather intervene. As a rule, white varieties are among the least robust during winter. I have only to instance Avalanche and the newer variety Souvenir de Petite Amie. The cuttings of these present a sorry appearance compared with many of the

yellow sorts at this time of the year, and yet later in the season they are among the most striking in regard to sturdiness of growth. There are many sorts remarkable for fine foliage in summer which do badly in winter. On the other hand, there are kinds which produce stout, healthy cuttings now that by and by exhibit a weakly aspect. Golden Dragon is a very good instance. Boule d'Or, again, a stout grower in its early stages, gives many cultivators trouble by taking on a yellow hue through the growing season. The grand Japanese variety Miss Dorothea Shea, too, has this habit. The mention of the last reminds me of some notes which have lately appeared in THE GARDEN in reference to its height of growth. One writer complained of the variety reaching 9 feet, and for that reason thought of discarding it. Of course, situation and seasons have a great deal to do with the height to which Chrysanthemums grow, but I cannot understand Miss Dorothea Shea showing such an extreme disposition to run up. I have always regarded this as a dwarf grower, or at most a variety of medium height when cultivated for show. With me it has seldom gone beyond 5 feet high. It would be better to try dwarfing by timely topping back than discard so fine a kind as the above undoubtedly is.

Last season I was much struck with a system of growing large Chrysanthemum blooms on dwarf stems, brought into prominence by a fine group at one of the Aquarium shows. Many of the plants were less than 3 feet high and the perfect blossoms were enhanced in beauty by remarkably fine foliage. The mode is to strike the cuttings from now to early April and let one stem only be selected to produce a single bloom. To delay the formation of the bloom bud, pinch back the plant when 6 inches high and in the final potting stage use pots no larger than 7 inches in diameter. Among Ferns and other green plants in a conservatory such specimens would be most effective. A quick and sure method of rooting the cuttings at this time of the year is to plant them thickly in shallow boxes. These may be placed in a greenhouse with a moderate temperature in the full sun, and sprinkled with water each evening. Do not mind if the leaves flag in the daytime; the moisture and darkness will make them stand up the following morning, and in a couple of weeks they will make sturdy little plants. Pot them off singly before there is time for them to become drawn, and then give cool frame treatment. The above is a good plan, too, for obtaining large show blooms of some of the late-flowering American varieties. Curiously, many sorts from this source are very late in giving bloom buds when grown on the well-known system of three flowers to a plant. W. G. Newitt is one, and I believe the magnificent blossoms of the sensational variety Philadelphia were obtained in this way. As there are a number of growers who now have this in their collections, they would do well to take off the tops of their little plants, root them as advised above, and be satisfied with one bloom to each, then allow the parent plant to throw up about two shoots and select the earliest flower-buds. To obtain the best results from this plan, high feeding should be adopted, the roots being confined to so small a space.

Chrysanthemum growers are now busy getting their plants into larger pots. Since the frost growth has been very rapid. There should be little danger now in removing the specimens into cool frames provided there be some means of protection during the night. It is advisable to

use pots of two sizes, namely, 5-inch and 6-inch. If the soil is sufficiently moist, so that it can be conveniently handled without sticking to one's fingers, ram it into the pots with a piece of wood. Loose potting induces a fast growth, but when the soil is made firm the wood and leaves become more solid. Stand the plants well apart, as well as provide abundance of air in favourable weather. At this time of the year some varieties have a tendency to produce flower-buds at the tips of the shoots. Although these are not desirable when the object is large blooms, I should say the plants are not permanently affected, as other shoots soon spring up. The stoutest may be selected and trained upwards. The varieties Viscountess Hambleton and Miss Anna Hartshorn are, perhaps, the most persistent in the above-named habit, and all we can do is pinch the buds off promptly until growing shoots obtain mastery over them.

H. SHOESMITH.

## ORCHARD AND FRUIT GARDEN.

### PEAR CHAUMONTEL.

IN many places this Pear is considered fickle and an indifferent grower and bearer, while in others it is a thorough success and highly appreciated for its large size and rich vinous flavour, together with its good keeping qualities, for though frequently fit for use in December I have had it in excellent condition up to the first week in March. There are numerous causes why this valuable variety should succeed so well in one place and fail in another only a short distance away, and I think aspect, shelter, stock, and mode of pruning exercise the greatest influence on its well-doing or otherwise. If the tree is planted with an aspect facing south, or nearly so, and fairly sheltered from east and west side winds, the position will be admirably adapted to it, and the blooms will set freely and the fruit swell up free from blemishes or other defects. Stock has perhaps more influence on Chaumontel than any other Pear, according to my experience. When grafted direct on the ordinary Pear stock I found the produce scanty and very spotted, but when double grafted the result left nothing to be desired. The finest crops of large fruit that I have ever seen were grown on a tree planted on the gable end of a stable facing due south. On the Pear stock had been worked Pitmaston Duchess, and on that again the Chaumontel. This connection suited the variety famously, as the growth was strong, clean, and short-jointed, and though no heavy crops were produced, they were regular, moderate ones of high quality. For growing as cordons the Quince forms a good stock, and the trees are very prolific if liberally supplied with plant food and otherwise well looked after. Another cause of failure lies in the pruning, for if the branches and spurs are too congested, immature wood and buds follow, and general debility soon sets in. Most practical men are well aware that all varieties of Pears that require a warm situation and soil must be so pruned that every spur or other portion of the tree has sufficient light and sun for the growth to become well ripened, and it is by acting on that principle so many gardeners are enabled to produce Chaumontel Pears that would be no discredit to the Channel Island growers who send us such magnificent fruit of that variety. W. G. C.

**Fig St. John's.**—This new variety is not grown so much as it deserves. I do not know of

any variety more suitable for hard forcing and one better adapted for pot culture. The new Pingo de Mel very much resembles it in colour and size—indeed, it is a richer fruit, but I have not found it such a good forceer, as the latter variety does not carry so many early fruits. It often attains a larger size than the St. John's. I do not know any of the older kinds of Figs which retain the autumn set fruits so well as the varieties named. The habit of the St. John's Fig is compact, so that the trees may be grown in a limited space. For summer fruiting I do not advise its culture, as we have larger and richer fruits, also varieties which give a much heavier second crop. Started in November, there is no difficulty in having ripe fruit in March.—G. W. S.

**Strawberry La Grosse Sucree.**—I am not surprised that good growers pin their faith to this variety for early forcing. I have always given it second place to Vicomtesse H. de Thury. It is strange how seasons affect the varieties, as last year our plants of Vicomtesse were all one could desire. They seemed to revel in the favourable growing season of 1893, and the result was very fine crops of fruit early the following year. This year Vicomtesse is much inferior to La Grosse Sucree, though both are given similar treatment. The crowns of Vicomtesse split badly and the

*Pear Chaumontel. From a photograph sent by Mr. Norman Blake, Bedford.*

stalks are very short. The crowns of La Grosse Sucree are the reverse, being very strong and full of flower, and in most cases single. To the growing season of last year I attribute the weak crowns of the Vicomtesse. Of course the former had the same weather to contend with, but this year they are full of vigour, and plants placed on shelves a month later to follow the Vicomtesse are nearly in at the same time, thus showing how seasons alter the character of the plants and the value of La Grosse Sucree in unfavourable weather.—W. I.

**A new Strawberry.**—The new Strawberry shown by Mr. J. Stevens at the last meeting of the R.H.S. was a surprise to many, as the fruits were equal to the finest forced Strawberries in May or fruit from the open ground in July. We have no knowledge of the parentage of this variety, and really it does not signify, for as a forcing Strawberry it well merited the award it received. In my opinion such fruits, whether new or old if not previously recognised, should get a suitable award. The grower's receipts for the past month from Covent Garden proved its worth for market and for its heavy crop so early in the year. I note that "A. H." (p. 192) gives valu-

able particulars as to its cropping qualities, and so well describes the fruit, habit of growth, and other details, that it is unnecessary to go at greater length into particulars. The grower readily gave advice as to treatment and other details of culture. He relies chiefly upon soot as a manurial agent. The compact growth, with its free-setting qualities, should make Stevens' Wonder Strawberry a valuable acquisition.—G. WYTHES.

**Stocks for Vines.**—No doubt great diversity of opinion exists as to the best stocks for the varieties of Grapes named by R. Katzer (p. 192), and the answers to his query will excite considerable interest amongst Grape growers. So far as my experience of stocks goes for that magnificent variety Muscat Hamburgh, I have found none to equal Muscat of Alexandria for it. Every year I have heavy crops from such a union, many of the bunches being 4 lbs. to 5 lbs. each, with berries of very large size and good colour, ripe early in August, and as the flavour is so superb, they are always wanted immediately they are fit to eat. Some able authorities recommend the Black Hamburgh as a stock for the above, and though I have grown it worked on that variety with fairly good results, I could never obtain the size of bunch and berry as on the Muscat. Madresfield Court, again, succeeds famously on Muscat of Alexandria, also on Black Alicante, and I found little to choose between them; the Muscat stock gave the finest berries, but the Alicante the broadest bunches and deepest colour. Gros Colman and Gros Guillaume, I believe, succeed best on their own roots, provided the soil is of a light and warm character, but where the compost is strong, Muscat of Alexandria for the former and Gros Maroc for the latter are good. At the same time I believe that the Muscat will answer as a stock for any variety of Grapes usually grown in a vinery, as I have yet to see any worked upon it fail to grow well and produce good Grapes.—W. G. C.

—R. Katzer (p. 192) asks as to the best stocks on which to graft Muscat Hamburgh, Madresfield Court, Gros Colman, and Gros Guillaume. Speaking from experience, I would strongly recommend the Black Alicante as the most suitable stock on which either to graft or inarch the Muscat Hamburgh. The finest crop of this grand Grape I ever saw was borne by a rod inarched on to this stock. The bunches were absolutely faultless, being large, well-shouldered, and with fine berries. The Black Hamburgh is usually quoted as the right stock for this capricious Grape, but I have seen many miserable results from the union, the berries shanking wholesale and the colour quite foxy. If R. Katzer has a healthy Vine of Alicante he cannot do better than try the experiment. Madresfield Court will do well worked either on Muscat of Alexandria or Black Alicante. I have it on the former in the early house, and it makes good wood and bears capital bunches, which always ripen well. In a later vinery I have it worked on the Alicante, and yearly large bunches and berries of first-rate quality are produced. I think there can be little doubt that the right stock for Gros Colman is Muscat of Alexandria. I have before referred to the magnificent examples of this Grape grown at Kelham Hall, near Newark, the Vines being inarched on to the Muscat. I have one young rod similarly inarched, and last season the bunch it bore was quite black by the middle of July, the house not having been started until the 1st of February. This season the Vine promises well, having duplicate bunches on every lateral. I

have also heard of several other gardeners who have been successful with Gros Colman on the Museat. As Gros Guillaume succeeds very well with me on its own roots, I have never inched it on to any other stock. The Vine under my charge has a certain amount of bottom-heat at its roots, the hot-water pipes running along the end of the border parallel with the drainage thereby heating the soil for some distance. At another place where the roots of Gros Guillaume are kept warm by hot-water pipes the crop is always even and good.—J. CRAWFORD.

**Pear Beurre d'Areberg.**—I was very pleased with the engraving of this valuable Pear with accompanying notes in a recent issue of THE GARDEN. We seldom hear of or meet with it, which leads me to think it is not so generally known as it ought to be. I have it here as a horizontal tree on a west wall, a cordon on an east wall and an espalier, in all which forms it does capitally. The fruit from the west aspect is certainly the finest. It comes into use during January in ordinary seasons, though in 1893 it ripened in December. It will keep equally as long as that excellent sort Winter Nelis, which is saying a great deal. The flavour is good enough to please even the most fastidious at so late a date, and the size of the fruit is just what one would choose for the dessert.—J. CRAWFORD, Newark.

#### RED SPIDER ON GOOSEBERRY BUSHES.

I NOTICE on looking over my Gooseberry bushes that the bursting buds of many of them terminate apparently in bright red points. On examining these through a lens I find the red points are clusters of minute spiders. Will these do any harm to the opening buds, and if so, what is the best remedy?—R. J. G. READ, *Eding.*

\* \* Many probably anticipate a certain amount of immunity from insect and grub attacks this season, thinking that the severe frosts of last winter must have proved very destructive among such enemies to vegetation generally. All too soon comes evidence to the contrary. Red spider in the open has not only survived, but, judging from R. J. G. Read's note, the pests are numerous on his Gooseberry bushes already. They may not greatly injure the buds, but the young leaves will, unless preventive measures are adopted, be soon overrun and eventually destroyed by them. These minute pests increase with great rapidity and draw so much sap from the leaves as to quickly check their progress, all before very long changing to a sickly colour and dropping off. This, in the case of Gooseberries, means the ruin of the crop, and not infrequently of the bushes too, as, unless they make a certain amount of top growth and retain their leaves long enough for these to perfect a strong bud at their base, the start next spring will be most feeble and the crop *nil*. In all cases, therefore, where red spider has been troublesome in the past timely preventive measures ought to be taken at once, not waiting till much of the mischief has been already done. Sulphur in either a powdered state or in a liquid form is perhaps the best remedy for red spider. A good formula for preparing a composition effective against mildew as well as red spider is as follows: Slake half a pound of lime in a pan, then add one and a half pounds of flowers of sulphur and six quarts of water, mixing thoroughly. Boil gently down to three quarts, keep stirring during the process, and after it has settled strain through muslin and bottle for use as required. Four ounces, or two wineglassfuls to three gallons of water, well mixing and thoroughly wetting every part of the bush by means of a syringe and sprayer, ought to be an effective dose, less sometimes proving sufficient. Sulphide of potassium is a simpler remedy, as in this case all that is necessary is to well mix one and a half ounces of this with three gallons of water and to apply with a syringe. Soap-suds duly strained through a piece of coarse canvas and diluted with an equal portion of clear soft water, frequently applied with a syringe, has been known to keep red spider under, and even

syringing with clear water nearly every evening will do much towards keeping the bushes clean. The stronger insecticides and soap-suds are best applied before the flowering period, and if this is not sufficient, repeat the dose after the fruit is set. Something should also be done towards promoting a more vigorous growth than formerly. Carefully fork away the surface soil down to the roots, and if caterpillars were abundant last season burn it. If the bushes are old, give a liberal dressing of good nearly decayed manure, covering this with soil, while a mixture of loam and manure will be quite strong enough for the younger bushes.—W. I.

#### Protecting tree stems from ground game.

—Adverting to the plan described by "A. D." (p. 171), I lately saw a somewhat novel idea put into practice upon some standard-grown Apple trees. Ordinary fish nets were cut into strips long enough to reach from the branches to the ground and sufficiently wide to cover the stem all round, hanging in folds of two or three thicknesses. The netting was not tied to the stem of the tree, but was allowed to hang loosely. I was told this was an efficient protection against hares.—E. M.

**Disbudding Peaches.**—"Foreman" (page 171) takes me to task for stating that young men are scarce who can properly disbud Peaches. Now although "Foreman" and many other young men no doubt thoroughly understand the work, my experience is that the great majority of them do not, and although there are many larger establishments than that of my friend mentioned in my note (p. 25) or the one I have charge of, the fact that in twenty-five years he has never had a man come to him who had done disbudding bears out my statement, and this in by no means a little place, as there are at least half-a-dozen Peach houses and as many young men in the bothy. Neither have I ever had a young man yet who could be trusted to disbud Peaches when he first came. However, if my article causes more knowledge and increased interest to be spread amongst young men on the matter, I shall be well satisfied. As to there being very many painstaking and energetic young men who can be depended upon to satisfactorily disbud Peaches I do not dispute, and I would only advise them to not neglect opportunities of learning how to do it properly, so that when the time comes they may teach their subordinates.—W. G. C.

**Strawberry Scarlet Queen.**—This is undoubtedly a fine early variety. It is, as regards flavour, infinitely superior to Noble, very early, coming in with me several days before that variety. It is of vigorous growth and crops well. The individual berries do not, however, come quite so large as those of Noble and Sir J. Paxton. One point in its favour is that the foliage is but little liable to mildew, a great recommendation now that Strawberries suffer so much from this pest. Those who want a well-flavoured early variety will do well to try Scarlet Queen.—J. C., *Byfleet.*

**Grape Mrs. Pince.**—Mr. Young does well to call attention to the requirements of this high-class Grape (p. 111). How seldom do we see it in even presentable condition, let alone possessing that high finish which renders first-class examples conspicuous. I know of no variety that will continue to produce such large and shapely bunches, in spite of its somewhat weakly habit of growth, as will Mrs. Pince from the same rods. Close spur-pruning is the method by which the best results are obtained. There is no occasion to encourage vigorous young canes from the base to obtain a regular crop of handsome bunches. So well does the wood mature with rational treatment, that an abundant crop is obtained at a minimum of labour. Although Mr. Meredith when at Guston grew his famous bunches of this Grape in a house devoted entirely to its use, it is not at all necessary to follow that plan to obtain satisfactory results. I grow this Grape along with Alicante, Lady Downe's, Gros Colman, Trebbiano, Madresfield Court, Gros Guillaume, and

Black Hamburgh, and never have any trouble to obtain a plentiful crop of shapely bunches. I generally employ fire-heat liberally with all late Grapes when in flower, as less trouble is experienced in getting a good set.—E. M.

#### APPLE IRISH PEACH.

ALTHOUGH this Apple is one of the most delicious early varieties in cultivation, it is condemned by some as being a shy bearer and unprofitable. While admitting that it is not a very remunerative Apple for market, I believe no other Apple can excel it for home consumption, and though not one of the heaviest croppers, it will produce regular and fair crops if cultivated on correct lines. Many of the shoots are furnished with a terminal fruit bud, and these buds as a rule produce the largest and best fruit. Supposing the pruner shortens back the major portion of these shoots, he is cutting away a large quantity of the finest and best placed fruit buds, and if the crop is light the fault lies not with the trees, but with the pruner. I never shorten back a shoot on Irish Peach unless it is throwing the head of the tree out of balance; the consequence is that most of the shoots in summer are terminated with a handsome Apple, which brings down the shoot by its weight in a gentle curve or arch, and by the check to the sap thus given most of the young branches or shoots are covered with fruit buds, to be followed the following summer with fruit. On standard trees no pruning is done except cutting out any branches that rub or cross each other, and I feel sure that if less pruning were done in this variety very satisfactory crops would be obtained, and it would be appreciated for its general excellence. Irish Peach, like a few other Apples and Pears, is the most pleasing to the taste if eaten the same day as gathered; if kept for a few days or weeks the quality suffers, until finally the flesh becomes mealy. However, if eaten as soon as ripe it is one of the most delicious and refreshing Apples grown, and should find a place in every garden where Apples are grown for dessert. I would suggest to those who have not been satisfied with their crops to try the plan of pruning mentioned; if they do, I think they will alter their verdict on this first-class Apple. W. G. C.

**Pear Leon Leclere de Laval.**—At page 95 Mr. Wythes speaks of two good stewing Pears. I would strongly recommend a third, viz., the above, which I consider the most prolific stewing Pear grown. It seldom misses cropping. When residing in North Hants I had a bush tree of this kind, and for ten years it never failed, although the tree did not grow in a favourable situation. Two years ago I obtained a bush tree, and last autumn I gathered from two to three dozen good-sized fruit from it. The fruits are not large when compared with those of some stewing kinds, but if they are thinned freely they are quite big enough to please good cooks. It is not a strong growing kind, hence it is suitable for planting in small gardens. It keeps well, as I have had it in good condition during February and March. Verulam I too can speak a good word for, having seen it give splendid crops in a most exposed garden in West Norfolk.—J. CROOK.

**Foreign fruit trees.**—I believe that in THE GARDEN last year I warned intending fruit growers against purchasing fruit trees from foreign sources because they could get them at a cheaper rate than from reliable British firms. It may possibly be worth while to repeat the warning, as I find that such purchases are rather on the increase than otherwise. A few days ago I saw specimens selected at random from a large order that had cost about 25s. per 100, poor, miserable things,

with a few inches of growth from the graft or bud, scarcely any roots, and those very dry and parched. If such trees become profitable within the next ten years I shall be astonished, and shall watch results with interest. My experience of these imported trees is not very large, but what few I have had under my charge were the reverse of encouraging, as they made very little progress for four years from planting, and after the lapse of that time they possessed little vigour and the fruit produced was consequently small. It is a very risky thing to buy these foreign trees, as the change of soil and climate may act very injuriously upon them, and it is very possible that, although the original cost may have been low, the trees may in the end prove very expensive. When first-class firms in this country offer maiden trees at about (on the average) 75s. per 100, and which are known to quickly develop into remunerative bushes, it seems absurd to spend money lavishly on what may be an absolute failure.—W. G. C.

#### SHORT NOTES.—FRUIT.

**Apple Winter Peach.**—This medium-sized cooking Apple does not appear nearly so well known as its merits deserve. For use during winter and early spring it is valuable. The skin, at first green, changes to cream colour, the flesh white and the flavour brisk.—E. M.

**Apple Winter Queening.**—This is suitable either for dessert or kitchen, and is especially valuable on account of its late keeping qualities. The skin is pale green, mottled and striped with red. While we have so many early and mid-season varieties we have few late Apples; therefore Winter Queening, though old, should not be lost sight of.—E. M.

**Apple Annie Elizabeth** is a really good late kitchen Apple that deserves more attention than it receives, as it succeeds in a variety of soils. The growth is quite erect. The branches when the trees are young require some little attention in order to give additional light and space to the inner parts of the tree. The fruit is large and prominently ribbed.—E. M.

### FERNS.

#### HARDY EXOTIC FERNS FOR THE WILD GARDEN.

I WAS very pleased to see in Mr. F. W. Harmer's interesting note on "Bog Plants," published in THE GARDEN of February 16 (p. 109), a reference made to certain robust-growing hardy Ferns of North American origin as being plants "which should be more frequently introduced into the choicer parts of the plantations that often surround our English gardens." His well-timed remark that these and "many other hardy exotic Ferns will take care of themselves or nearly so, and that an admixture of the foreign species with English Ferns in the wild garden would make it a much more interesting place than it sometimes is," I consider, most judicious and deserving special attention. In most gardens now-a-days the more plants requiring but little or no attention that can be introduced the better, for in gardening matters, and especially in garden expenditure, economy and retrenchment appear to be the order of the day, and the question of reduction of labour is a point which is carefully studied by amateurs and gardeners alike, especially when applied to outdoor gardening. I fully agree with Mr. Harmer's statement respecting all the Ferns named in his note, which, as he says, are at their best when planted in close proximity to the water, and I quite agree with him as to the uses to which these plants can be put with advantage in the wild garden, where nothing can be more effective than clumps of *Onoclea sensibilis*, *Struthiopteris pennsylvanica*, or any of the *Osmundas* planted by the brook-side.

The three *Osmundas* mentioned in Mr. Harmer's list, viz., *O. cinnamomea*, *O. interrupta*, and *O. spectabilis*, are all equally beautiful as decorative plants, and, on account of their singular mode of fructification, two of these possess a very peculiar appearance, which greatly adds to their attraction. Thus, when fertile,

*OSMUNDA CINNAMOMEA*, which is stated by E. J. Lowe to have been introduced into the Royal Gardens, Kew, in 1772, and which is found in Japan, Manchuria, Brazil, and Mexico, as well as in North America, cannot be mistaken for any other known kind, as the fertile fronds, which rise from the centre of the plant in early spring, are at first densely covered with a woolly substance of a light brown colour, but when unfolded, the abundant spore masses give them the characteristic cinnamon-brown colouring not found in any other known species. The barren fronds soon follow the fertile ones; they are regularly disposed and form, as it were, a magnificent light green vase, within which the brown plumes of fructification stand erect. Equally distinct and striking is

*O. INTERRUPTA* or *CLAYTONIANA*, which, though considered a North American species, has, according to Col. Beddome, been found on the Himalayas up to 10,000 feet elevation. Its barren fronds, which form the outer part of the plant, are of a bright pea-green colour and soft texture, while the fertile ones, which are usually taller, stand close together, nearly upright in the centre of the crown. They never bear fructification at their summit, as is the case with our *O. regalis*, nor are they ever totally fertile like those of *O. cinnamomea*; their fertile leaflets are situated somewhere near the centre of the frond, most frequently a little above the middle.

*O. SPECTABILIS*, also found in gardens under the name of *O. gracilis*, is of less dimensions than the foregoing; it is a charming delicate looking Fern, also native of North America, producing in great abundance its slender fronds of a peculiarly metallic-green colour, and seldom more than 15 inches long.

*Nephrodium Goldieanum*, *N. intermedium*, and *N. marginale* are all strong-growing North American species, producing their massive fronds from occasionally agglomerated, but usually solitary crowns, and the same remarks also apply to *Athyrium Michauxii* and *Aspidium acrostichoides*; while, on the contrary, *Cystopteris bulbifera* and *Woodsia obtusa* invariably show clustered or agglomerated crowns. The former,

*CYSTOPTERIS BULBIFERA*, a singular and elegant species, taking its name from the large fleshy bulbils borne on its upper leaflets, is essentially a North American species, but quite as hardy as any of the British kinds. It is found growing wild on dripping rocky banks and in moist places amongst rocks, and sometimes where there are no rocks, from Canada and New England to Tennessee, and westward to Wisconsin and Arkansas. Its fronds, which are of a thin, papery texture, and which wither at the first appearance of frost, seldom exceed a foot in length. The bulbils, by which this species is readily distinguished from all others and by means of which it is easily propagated, are usually disposed at the base of the leaflets on their under side.

Eaton states ("Ferns of North America," vol. ii., p. 190) that

*WOODSIA OBTUSA* grows on moist rocks and stony hillsides, and is not rare from New England to Wisconsin and Georgia and Central Alabama, but always in damp positions. Although this is the strongest growing species known, its very elegant fronds seldom measure more than a foot in length.

Although they are quite hardy and may be easily acclimatised in this country, all the foregoing being plants producing their fronds from crowns do not spread so rapidly as the follow-

ing, also contained in Mr. Harmer's list, and which are provided with rhizomes spreading apace and taking firm possession of the ground whenever they find themselves in a suitable position, that is to say, a naturally damp place and a ground formed in greater part of decayed vegetable matter. It is in such situation and exposed to the action of the air, though not of the full sun, that the beautiful

*ONOCLEA SENSIBILIS*, which Lowe tells us is the oldest of exotic Ferns introduced to Europe, having been imported from North America in 1699, is seen in all its glory. Its barren fronds, which under these circumstances, as stated by Mr. Harmer, attain 3 feet in length, are of very pleasing, soft pale green colour above and slightly bluish on their underside. They are very sensitive to cold temperature, for the first autumn frost generally destroys them. The fertile fronds, which are sparingly produced, are so unlike the barren ones, that they do not appear as if related to each other; they are about half the height of the barren ones, perfectly rigid and nearly black when fully developed, and instead of being cut down by the frost they dry up in winter, but remain erect during the following summer, so that a fruiting plant often bears fertile fronds of two years' growth.

*ADIANTUM PEDATUM*, the Canadian Maiden-hair Fern, is the only *Adiantum* which we know as perfectly hardy here, and we have it on the authority of E. J. Lowe that in January, 1854, plants of *A. pedatum* lived out of doors with the temperature of 6° below zero of Fahrenheit's thermometer. It is possible that if in some places in England failure has attended the attempt at acclimatising this species outside, it is due to the fact that the underground rhizomes are generally kept too close to the surface of the ground, so that they are not protected in winter by either leaves or snow, and thus feel more keenly the effects of cold, though usually less severe than that of its own country. It is a plant of thoroughly distinct habit, its bird's-foot-shaped fronds, of a pale green colour and delicate texture, borne on long black or dark purplish stalks, attaining about 2 feet in height and forming good bushy masses of foliage. Eaton, in vol. i. of "Ferns of North America," states that in Canada this Fern grows abundantly in moist woods, especially among rocks, and that in such places it forms under the shelter of trees patches covering several acres at a stretch. In such a position the underground rhizomes often lie buried 6 inches deep, or even more in decayed vegetable matter produced through the annual fall of leaves, the fronds having to penetrate through this before they reach the surface of the soil. According to eye witnesses, these masses of *A. pedatum* with light pea-green foliage are a grand sight.

*POLYPODIUM HEXAGONOPTERUM*.—This essentially North American Fern is found in moist woodlands from Canada to Florida, where it delights in a naturally cool position and in a soil of a moist, spongy nature. Its slender and wide-creeping rhizomes, sometimes 1 foot long and of a somewhat fleshy nature, creep just beneath the surface of the ground, and its handsome fronds, which in shape somewhat resemble those of our common Beech Fern, but attain much larger dimensions, are of a particularly pleasing light green colour and produced abundantly through the whole summer.

*STRUTHIOPTERIS PENNSYLVANICA*, commonly known in North America as the Ostrich Feather Fern, is described by Eaton in vol. ii. of "Ferns of North America" as being one of the finest Ferns of the New World, for he states that "Its grand, vase-like circle of foliage is often higher than a man's head and sometimes extends above his utmost reach, its barren fronds attaining 10 feet in length." It has never come to my knowledge that the plant has attained such dimensions in this country. The places where the plants mentioned by Eaton were found growing were low grounds of fine alluvial soil, subject to the overflow of rivers from the Saskatchewan and Lake

Winnipeg to New Brunswick, and southward to Pennsylvania and Illinois. In such position the underground rhizomes or stolons, which extend to very long distances, are produced in great quantities and very soon form quite a little forest of young plants. As in the *Onclea sensibilis*, which also thrives best under similar conditions, the fertile fronds, entirely distinct from the others, are much shorter than the barren ones and much contracted. They are produced only in the autumn or late in the summer, and disposed in the middle of the crown, where they stand perfectly erect.

To the list of hardy exotic Ferns given by Mr. Harmer may be added several species provided with rhizomes, such, for instance, as

*DICKSONIA PUNCTILOBA*, also a native of North America, where it is known under the popular name of Hay-scented Fern. Its finely-cut and very elegant fronds, about 18 inches long, are abundantly produced from slender rhizomes, which creep extensively 1 inch or 2 inches below the surface of the ground. In its native habitats it is found growing in moist woods and often in low, grassy places. It is, according to Eaton, a common Fern in New Brunswick, Canada and the Middle States of North America.

*WOODWARDIA AREOLATA*, or, as it is also called, *W. angustifolia*, is a very handsome species of medium dimensions and essentially of North American origin, being, according to Eaton, plentiful in certain localities from Massachusetts to Florida and Louisiana, where it is found growing in swampy woods and apparently never very far from the rivers. The fertile and barren fronds in this species are totally different; the latter, by far the more abundant, are about 2 feet long, while the fertile ones are considerably taller and borne on longer and much darker coloured stalks. In

*WOODWARDIA VIRGINICA* we have another North American species especially adapted for cultivation along the water edge of our brooks and ponds. Eaton, in his splendid work "Ferns of North America," speaking of this particular plant, gives its range of habitat as from Canada and New England to Florida and westward to Louisiana; he also states that it grows in swamps often where the depth of water renders the plant almost inaccessible, and that in seasons when the ponds are nearly dry the root-stock may be traced a long distance from the fronds, as he has personally torn up a root-stock or rhizome 10 feet long and over 6 feet undecayed. This rhizome, which is nearly as thick as a man's little finger, irregularly branched, soft and fleshy, creeps just beneath the surface of the firm mud at the bottom of the shallow ponds in which it prefers to grow.

These, intermixed with such of our own British Ferns as *Osmunda regalis*, *Lastrea Thelypteris*, numerous forms of *Lastrea Filix-mas* and *Scolopendrium*, all of which enjoy a wet or constantly moist position in the wild garden, would when once established require no further attention, but year by year produce their elegant foliage, which would form a special feature in the natural garden, as other Ferns of a more tender nature do in a winter garden. All the above-named plants are perfectly hardy, even such a winter as the late one having no ill-effects upon them. With a little care and attention, several of the Japanese Ferns usually grown in houses could also be used with advantage for planting out-of-doors, and by their bolder and more massive foliage produce a splendid contrast in the wild garden. Among these may be noted *Cyrtomium anomophyllum* and *C. falcatum*, *Lastrea Standishi*, *Lastrea atrata*, *L. opaca*, and *L. erythrosora*, *Polystichum setosum*, *Dietyogramma japonica*, &c., all of which are already well established in the woods of some favoured and sheltered English gardens. A covering of dry leaves over the crowns is all the protection they receive during the winter, at other times requir-

ing no more attention than any of the commonest of our British Ferns. Mr. Harmer's remarks respecting the damp position most favourable to the Ferns he names and to others goes far to prove the fallacy of "giving a rest" to hardy Ferns grown in pots and keeping them, as many people still do, dry at the roots from November to February or March, at which time it is found that some have taken to "slumbering" to such an alarming extent, that they cannot be awakened even by the spring rains and the warmth of summer days, while those which after a long spell of dry treatment can be induced to make a start are usually very weak, and show unmistakably that the "rest," instead of having been beneficial to them, has really weakened their constitution to a very great extent. This is very easily accounted for, as if we observe the course of Nature we find that, instead of our native Ferns being dried up in winter, it is during that portion of the year that they are naturally provided with the greatest abundance of water at the roots. In the case of such species as *Polypodiums*, *Blechnums*, *Asplenium* *Adiantum-nigrum*, which are usually found growing on hill-sides, amongst bushes and under the hedges, the rain-water, more plentiful in winter than in summer, reaches them more readily and in much greater quantity on account of the trees and bushes overhanging them being deprived of their foliage, in consequence of which the ground under them is kept constantly wet during the period of four or five months of autumn and winter. As regards *Osmundas*, *Scolopendriums*, certain *Lastreas*, *Athyriums*, many of these are found growing wild in low-lying districts where for weeks, sometimes even for months, they are kept totally under water through the annual overflow of some river or an excessive quantity of rain. It is therefore evident that a resting or dry treatment of hardy Ferns, British or exotic, while they are in a dormant state is pernicious to them, as it causes their crowns to become annually weaker and weaker. Those species provided with rhizomes on which the plants are dependent for the strength of their new growth become shrivelled and in course of time thoroughly exhausted, instead of increasing in numbers, size and vigour, as they do when in a wild state and under the influence of natural and constant moisture. It may safely be said that with Ferns, as with most other plants, it is by far the best to imitate Nature as far as practicable, a course which in this case may be followed without trouble or inconvenience and at very little expense. DOODIA.

*Onclea sensibilis*.—Mr. Harmer's note on this (p. 109) is instructive and interesting. He very properly shows my treatment of this plant as somewhat opposite to Nature. I did convey the idea of growing it on a dry bank, whereas the habitat of the species is the cold swamps of Canada, but it did not belong to the theory that I was then discussing to give an explanation why I so planted it. I feel called on now, however, to do so. If you take a plant native of a cold, swampy habitat in colder latitudes than our own, unless you employ some counterbalancing means, you get the plant into much earlier growth than is desirable. That would not matter so very much, but this Fern chanced to be one whose young fronds cannot endure our late frosts. My point therefore was to give it a set of conditions that would hold it back from early growths, and so prevent injury to what should be the finest fronds. I am successful in this respect, and as evidence that the big sand-stones under and around which the rhizomes run afford the desired amount of moisture, the one plant set, perhaps, eight years ago has spread immensely. Do we not also find other plants respecting which it

would be better could we keep back their early growths, for instance, *Dicentra spectabilis*, from Siberia? Still further, we also find that some plants found wild in moist or boggy surroundings do better in this country treated as ordinary border plants, such as the Pampas and other Grasses.—J. WOOD.

**Ferns for a wall** (*H. F. K.*).—The following are among the most suitable Ferns of rapid growth which may be used for growing on a wall in a fernery with average temperature—55° to 65°:—

<i>Adiantum capillus-Veneris</i>	* <i>Phlebodium aureum</i>
<i>Mariesii</i>	* <i>Polypodium nigrescens pustulatum</i>
<i>cuneatum elegans</i>	* <i>verrucosum</i>
<i>fragrantissimum</i>	<i>Pteris cretica</i>
<i>venustum</i>	<i>albo-lineata</i>
<i>Blechnum lunceolatum</i>	* <i>longifolia</i>
<i>Hypolepis distans</i>	* <i>Stenochlæna scandens</i>
* <i>Nephrolepis davallioides</i>	* <i>Woodwardia radicans orientalis</i>
* <i>furcans</i>	
* <i>exaltata</i>	
<i>pectinata</i>	
<i>tuberosa</i>	

Others, such as *Davallia bullata*, *decora*, *dissecta*, *elegans*, *immersa*, *Mariesii*, and *Tyermanni* are also very suitable for that purpose, but their growth is not so rapid as that of the above-named species. The plants marked \* are the largest growing kinds. As yours is a light place with no creepers covering the roof, you should have no difficulty in growing and flowering—

<i>Abutilon Boule de Neige</i> (white)	Begonias of sorts
<i>Boule d'Or</i> (yellow)	<i>Gardenia citriodora</i>
<i>Sanglat</i> (bright red)	* <i>Gloriosa superba</i>
* <i>Eschymanthus Lobbianus</i>	* <i>Hoya carnosia</i>
* <i>grandiflorus</i>	<i>Impatiens Sultani</i>
* <i>splendidus</i>	<i>Libonia floribunda</i>
<i>Anthurium Scherzerianum</i>	<i>Meyenia erecta</i>
<i>Andraeanum</i>	<i>Rivinia humilis</i> (scarlet berries)
* <i>Aristolochia elegans</i>	* <i>Stigmaphyllon ciliatum</i>
	<i>Torenia asiatica</i>
	Baillonii

If you wish to have Orchids to flower in such a place, the most suitable are *Ada aurantiaca*, *Cochlidia Noezliana*, *Celogyne cristata* and *C. ocellata*, *Dendrochilum glumaceum* and *filiforme*, *Phaius grandifolius*, *Zygopetalum crinitum* and *Maekayi*. The plants marked \* are of a climbing nature.

**The black Vine weevil**.—In taking down part of my fernery (cork), amongst the soil were some small maggot-like insects. To-day I repotted some *Adiantums*, and in one 8-inch pot I found thirty-four of the same kind of maggot, a few of which I send you. Will you oblige by saying what they are, and how to prevent breeding, and mode of capture?—WM. LEE.

\*\* The maggots you find at the roots of your Ferns are the grubs of the black Vine weevil (*Otiorhynchus sulcatus*). Besides destroying the roots of Ferns they attack those of *Primulas*, *Cyclamens* and various other soft-rooted plants. The beetles you find later in the season in your Ferns at night are the parent insects; they feed on the foliage of many kinds of plants, and are particularly fond of Vines. I do not know of any practical way of destroying the grubs but picking them out from among the roots. It is almost impossible to make insecticides reach them without injuring the plants. As regards destroying the beetles, you cannot do better than search for them with a light, as you have done. Laying the plants on their sides on a white sheet during the day is a useful thing to do, as the weevils sometimes drop off as soon as a light at night shines on them. If they fall into the pot among the stems of the fronds they are not easily seen, but on a white sheet they cannot escape notice.—G. S. S.

**Grubs infesting Maiden-hair Ferns**.—In reply to the enclosed from F. Thirlby, the grubs you find under the crowns of your Maiden-hair Ferns are those of the black Vine weevil (*Otiorhynchus sulcatus*), a common and most destructive pest. These grubs live at the roots of many kinds of plants, *Cyclamens*, *Primulas* and Ferns being their special favourites. From their posi-

TEA ROSE DUCHESSE D'AUERSTÄDT.

tion it is impossible to make any insecticide reach them with sufficient strength without injuring the plants, so that searching for the grubs at the roots is the only practicable way of getting rid of them. The weevils are also very injurious; they feed on the leaves and young shoots of various plants, Vines being very attractive to them. They are about three-eighths of an inch in length and entirely black in colour. The head is produced into a long snout, which bears a pair of longish antennae. They feed at night and are seldom seen during the day, as they hide themselves most carefully under some shelter. When a plant is found to be attacked by them it should be laid on its side if possible with a white sheet underneath it; then when it is dark it should be carefully searched with a strong light. The insects often fall when disturbed, and they may then be caught on the sheet. The plant should be suddenly tapped or shaken, in order to make them fall.—G. S. S.

## GARDEN FLORA.

### PLATE 1007.

#### THE CLIMBING DIJON TEAS.

(WITH A COLOURED PLATE OF DUCHESSE D'AUERSTADT.\*)

THE vigorous climbing Dijon Teas are appropriately named, because they all in a great measure possess the distinctive merits of that noble Rose. Those who would cover their walls with Roses of undoubted hardiness and have flowers for a long season will not be disappointed if they grow the best varieties in this section. Not only on walls, but elsewhere about the garden these Roses should be planted where there is no necessity to restrict them. A few of the more recent additions to this class appear to need the several benefits that follow from growing them upon a wall, but even these abundantly repay the cultivator who, having found out their requirements, endeavours to supply them. Although all the best of the Dijon Teas have been enumerated at different times, it will perhaps be a useful guide to some if their names are once more given and their distinctive or special merits briefly stated:—

**GLOIRE DE DIJON**, known to every lover of Roses, needs no praise. On walls, on fences in any aspect it flowers finely. It should also be planted in bold masses in the garden away from any structure.

**BOUQUET D'OR**, another most important kind, is one of the grandest Roses in our gardens. It blooms more abundantly than Gloire de Dijon, whilst its flowers are of better shape—in fact, it is the very best of this race, good always on walls, fences, or as a large mass in open beds and borders. It was figured in *THE GARDEN*, February 22, 1890.

**MME. BERARD**, a very handsome, full, well-formed Rose, is easily distinguished by its long red-barked, almost thornless shoots. It is a vigorous grower, rather subject to mildew against walls in a sunny aspect, but not so liable to this pest on fences. As a bush it also does well. Its flowers are pale salmon fringed with yellow, which deepens into a rose tint.

**EMILIE DUPUY**, another distinct kind, produces flowers of great substance. The bud is so hard as to give an impression that the flower can never come to perfection, but gradually it unfolds into a bloom of splendid form, the colour a clear pale fawn-yellow. Some have found a difficulty in distinguishing this Rose from Bouquet d'Or, but it is easy to do so. Emilie Dupuy invariably produces one flower on a lateral shoot, whilst Bouquet

d'Or gives clusters of three or more. This Rose was figured in *THE GARDEN* of May 10, 1890.

**DUCHESSE D'AUERSTADT**, now illustrated, and one of the more recent additions, does not quite reach the high standard of general merit that characterises all the preceding varieties. It has come rather short of the early estimate that was formed of its worth. Sent out in 1887, a summer of unusual brightness, the sun favoured the production of splendid flowers. It is said to be a seedling from Rêve d'Or, and possesses extraordinary vigour. The flowers shown in the accompanying plate were cut from large bushes growing in an open border. A wall with a sunny aspect will give the best results with flowers of the richest colour, yellow, deepening into nankeen in the centre. The petals are thick, and the flower one of great substance.

**HENRIETTE DE BEAUVEAU**, also sent out in 1887, is a satisfactory Rose on a wall with plenty of room to lay in its long rambling shoots. Its flowers, freely produced, are of a clear canary-yellow colour and very sweet-scented.

**MME. CHAUVRY**, which first appeared in 1886, is the result of a cross between Mme. Berard and W. A. Richardson. In its leafage, comparatively thornless shoots, form and fulness of flower it partakes closely of the character of the former parent, whilst its colour is a rich, deep apricot-yellow. When first sent out it flowered well in the open and upon walls, but it does not seem to have found much favour yet in gardens.

**KAISERIN FRIEDRICH** is one of the most recent additions deserving mention. It is said to be a cross between Gloire de Dijon and Perle des Jardins. It has the vigorous climbing habit and handsome foliage of the Dijon varieties, producing flowers of a pale fawn yellow, which especially in autumn have rosy suffusions of colour.

**MME. B. LEVET** and **MME. EUGENE VERDIER** may be taken together, as they agree in being decidedly shy bloomers, though lovely and distinct in shape and colour, the former clear lemon-yellow, the latter deep orange-yellow, both exquisitely sweet-scented.

A. H.

## THE WEEK'S WORK.

### THE KITCHEN GARDEN.

**EARLIEST TOMATOES.**—Plants for producing ripe fruit in May which were sown in January and duly shifted into 4½-inch pots will now be ready for removal into their fruiting pots. If the happy medium has been aimed at in regard to temperature, long-jointed, leggy plants will have been avoided, and the extremities of the leading growths will already be showing flower. In potting this early lot I always cut off several of the lowest leaves and sink the plant well into the pot. By this means additional roots are emitted from the stem, and the first clusters of fruit are brought nearer to the bottom of the trellis. Use 10-inch pots, drain well, and have good holding loam, adding road grit or mortar rubble as a corrective. Grow the plants as near the roof glass as possible, training to a wire trellis on a single stem, and keep all side shoots closely pinched. A temperature of 60° at night is very suitable, admitting air freely on all fine days, but avoiding cold currents, closing early to make the best of sun heat. Beware of animal manure in potting, as this induces rank, unfruitful growth, and a stimulant can always be applied when the crop is set. Avoid also freshly cut turf, as if this contains any wireworm they will probably tunnel up every stem and ruin the plants. Soil that has laid a twelvemonth should always be used. I do not approve of syringing overhead, nor yet of shutting up with too much atmospheric moisture. This encourages weak flower-trusses and makes way for disease. An inch of soil is quite sufficient for covering the roots with at first, slight top-dressings being given as new colonies of fibres show themselves. Early in the year artificial fertilisation is needful, no damping of floors being practised in

the forenoon, that the pollen may have a chance of drying. Plants raised from cuttings last autumn and which were potted on early in the new year are now yielding a useful lot of fruit. As soon as the limit of trellis room has been reached and a full crop set, give the last surface dressing of loam and farmyard manure. This will aid in swelling up fine fruit. Do not, however, apply it until the above-named stage is reached.

**MAIN CROP PARSNIPS.**—The present is the best time in the majority of gardens to get in the main crop of this nutritious vegetable. For an early row a week or two since I recommended the old Hollow Crowned variety. Now, however, the Student is to be preferred. A good depth of friable soil free from large stones must be chosen if symmetrical well-flavoured roots are required. Give plenty of room between the rows and tread very firmly both before drawing the drills and after the seed is sown. If the ground is not in good condition, do not dig in strong manure, but rather stir in some approved fertiliser and give additional broadcast supplies when in free growth.

**MUSHROOMS.**—As a rule it is not advisable to make up fresh beds in the majority of houses after this date, as by the time the spawn is in full operation the sun raises the temperature to such a degree that unsatisfactory growth coupled with wholesale attacks from grub generally ensue. In isolated houses, however, favoured with special shade and coolness, even April-formed beds sometimes prove fertile and lasting. Beds now in bearing should be encouraged to last their normal time by maintaining a cool moist atmosphere, using little or no fire-heat. Much more water will also be needed on the surface of the beds than heretofore, but this must still be applied in a luke-warm state and saturation must be guarded against. Sometimes apparently exhausted beds may be again brought into a more or less productive state by soaking them well through with warm water, into which a medium quantity of salt has been stirred.

**OPEN-AIR BEDS.**—Where an all-the-year-round supply is necessary, it is advisable to have a couple of good large beds in the open air; the first of these to be made up at the present time for May bearing, the second following six or seven weeks later on. In forming such beds position is of much importance. I do not advise a north aspect, as these beds must be made of good depth, and if gloomy, unless weather occurs in May and June, the heat is not maintained sufficiently to induce the spawn to run freely and the yield is consequently unsatisfactory. I have seen good crops from beds made beneath large trees, the foliage shading from the direct rays of the sun by the time shade is most needed. No fear need be entertained of drip, as if the beds are made in ridge form, which is the best, they can be well covered with Bracken or straw and wide boards nailed together and placed on either side, meeting at the top and making the whole waterproof. It is sometimes difficult to obtain sufficient horse droppings for such spacious beds, but dry Oak or Beech leaves may be added in the proportion of one part to four of the horse manure. Some good tuffy soil may also be incorporated. If the spawn is inserted when the heat stands at 90°, the bed may at once be soiled and covered down, as there is not much fear of any reaction, which sometimes occurs in beds under cover.

**CUCUMBERS.**—January-sown plants will now be coming on apace, and will soon supplement the winter fruiterers which are still bearing freely. If any extra early fruit is formed on the main stem or on the first laterals, it will be wise to remove it. If there is ample room for the plants, do not pinch too rigidly, but allow the growths to extend somewhat, reducing their numbers if too crowded. This will encourage the formation of a multitude of roots and lay a good foundation for free and continuous cropping. As each fresh colony of young roots appears surface the bed with good rough loam and road grit, adding a little artificial manure in the case of weakly

\* Drawn for *THE GARDEN* at Gravetye by H. G. Moon, July 14, 1894. Lithographed and printed by Guillaume Severeys.

plants, but withholding all stimulants where growth is strong enough. A night heat of 70° when mild weather prevails will be suitable, closing early and dewing the foliage over with tepid soft water. The floors also must be kept moist by sprinkling thrice daily. Where plenty of house room is at command another sowing may now be made for succession. I always grow Perpetual Bearer for first and second earlies, as it possesses every good quality which may be expected in a Cucumber. Much bottom-heat after this date will not be necessary when sowing, as if the pots are stood on Moss on warm kerbs or shelves and the soil kept on the dry side, the seedlings will appear in a few days. When sowing, leave a slight margin for earthing up later on; this will steady the plants and induce new roots.

J. CRAWFORD.

### FRUIT HOUSES.

**FRUITING PINES.**—If the advice given previously has been followed the early fruiting Queens will now be making good progress. During February little growth was made, the severe cold and lack of sun being unfavourable to the plants. The plants now throwing up their fruits freely will need encouragement in the way of liquid food and a moist atmosphere to induce robust growth. If the bottom-heat is supplied by hot water there will be no difficulty in maintaining a temperature of 85°, and it is well to shift the plants about as little as possible at this stage. I previously noted the importance of securing a steady bottom-heat at this season. Many plants will be in flower, and being later than usual will need plenty of assistance, but during the flowering period syringing overhead should entirely cease. After the plants are past the flowering stage more moisture is necessary. Many good growers do not damp overhead till the flowers are set. Should the bottom-heat get low lose no time in adding fresh warm material, doing the work carefully and quickly. The plants after this date will take regular supplies of weak, tepid, liquid manure or guano water, and the spaces between the plants may be occasionally damped over with the fertiliser. This charges the atmosphere with ammonia and promotes a luxuriant growth. The evaporating pans may also be filled at times with weak liquid manure. It is well now to keep the plants in a uniformly moist state, but avoid excess or saturating the soil. Large plants that have failed to fruit will need different treatment. It is advisable to stand them at the coolest part of the house, keeping them rather dry at the root till they push up their fruit. The house should be closed early, allowing the thermometer to rise, at the same time syringing freely, the night temperature being as near 70° as possible, with an increase of 5° to 10° during the day and air on. Keep a sharp look-out for drip in badly glazed pits, as this soon ruins a good fruit in its early stages. In dull weather it will be found best to damp only the floors and walls.

**SUCCESSION FRUITERS.**—The large plants of Smooth Cayenne, Rothschild and Jamaica will now be growing freely. To these should be added the late batches of Queen. Repotting of growing stock should now be general. If any of the plants are starved or in a sour condition, careful repotting will not prevent the plants fruiting, but they will require careful watering and regular warmth at the roots for a few weeks. Large plants at all loose should have some pieces of dry turfy loam packed round the collars and the surface made firm. Succession plants requiring a good shift, if at all dry at the root, should be gradually moistened with tepid water before repotting and the plants encouraged to grow freely. The compost, pots and clean drainage should be all prepared before the work commences, so as to get through the potting as expeditiously as possible. After potting give a liberal bottom-heat, say 85° to 90°, and the water used should be of the same temperature as the bottom-heat, but the plants must be kept on the dry side till new roots are made. In potting it is well to ram the soil as

firmly as possible, and with robust plants to mix a small quantity of bone meal and soot in the compost. Many growers use bones as drainage, but I prefer bone meal in the soil; the roots find it more quickly and get more benefit.

**YOUNG PLANTS.**—Many will this season have deferred potting up late suckers of last year and the general stock of what may be called the late successions. A few of these potted up early last season will be strong enough for a final shift. They may be treated as advised for succession fruiters and placed in that division, thus getting more generous treatment. The unfavourable weather having delayed potting, it is well to push on with the work now and to get a liberal quantity of heating materials for bottom-heat in readiness, if the small plants are grown in frames or pits not heated by hot water. Obtain the best fibrous loam possible and preserve it in a nice condition by placing under cover. Shake out all fine or dusty particles and use such additions as advised for larger plants (bone meal and soot), with abundance of clean drainage. Plants in 6-inch or 7-inch pots if strong and healthy will now require pots four sizes larger. In repotting remove old drainage and loose soil and spread the roots out at the base on the new material. Plunge in a bottom-heat of 85° to 90°, give a night temperature of 60° to 65°, and 5° to 7° higher by day, syringing walls and surfaces, but only water the plants sparingly till new root-growth is made. Small or late suckers may have a shift, and any plants sour or deficient of roots should be shaken out and repotted in small pots.

**EARLY FIGS IN POTS.**—The weather during the early part of the year was most unfavourable for early forcing, and the first crop will with some varieties be thin. The newer kinds, St. John's and Pingo de Mel, appear to set a first crop with more freedom than any varieties I have grown. Small plants in 10-inch and 12-inch pots carry a lot of fruit, and with care will ripen well. Plants in a small pot and with much leafage require a lot of food in the way of liquid manure, but few fruits resent excess of water so much as early pot Figs. If at all saturated, the fruits turn yellow just before the final swelling and drop. It is important to have free drainage and to use the liquid manure and water in a tepid state, soot water given in a clear state being a valuable fertiliser. As the ripening period approaches the syringe must be used with care, well damping all available parts of the trees, but not directly on the ripening fruits. These soon burst if ripe. The flavour of the fruit is much improved if left till the last moment. To get flavour it is important to give plenty of light, removing all superfluous growths and ventilating freely in warm weather, shutting up early to retain sun heat and charge the air with moisture. Plants that have not been top-dressed should receive attention, as the trees will repay for extra food which assists in forming a heavy second crop. The earliest pinched shoots will ere this be growing away freely and the small Figs swelling. These require liberal treatment. All later growths should be stopped as advised for earlier shoots at the fourth or fifth joint, and small, weak wood removed entirely. Suckers at the base must be removed, and as soon as the first fruits are gathered a temperature given similar to that for early Vines.

**SUCCESSION FIGS AND PLANTED-OUT TREES.**—It is not often necessary to thin out the first crop of fruit on planted-out trees. Last year the fruits set very thickly, doubtless owing to the favourable season of 1893 ripening the wood. Where thinning is necessary, no time should be lost in going over the trees. Stopping will be the most important work, and must be attended to well into July, when the second growths must be left to ripen. Trees that are at all weak should be fed, giving a good mulch to those cropping freely; others that are shy fruiters should get plenty of moisture, but it is not wise to feed, as Figs which fruit sparingly have a tendency to grossness. Trees with their roots restricted to a certain space crop better, and feeding may be readily adopted, giving dressings of turfy loam, with a

liberal quantity of manure and bone meal added. The temperature may now range from 60° to 65° at night, with an increase of 10° to 15° by day, syringing freely twice a day, closing early and damping all parts of the house. Should rust appear on the foliage, overhead syringing must be done with care. It is well to have the foliage dry by sunset and to admit a little air early in the day; this removes moisture, makes the leaves stouter, and the new growths less sappy. By treating permanent trees well there is a good second crop, and though the fruits will be smaller, there will be more of them and of first-rate flavour. Crowding the wood is the greatest evil at this stage, and those who want quality in the fruits will do well to admit plenty of light, removing shoots not required and avoiding a high night temperature.

**HARDY FIG TREES IN THE OPEN.**—These will in many gardens have been closely covered, and it is well to gradually uncover after severe frost. Many who did not cover their trees will this season have had them cut down to the soil, and in such cases it will be impossible to get fruit this season. The grower must endeavour to build up strong fruiting wood for another year. In the selection of wood it is well to bear in mind that strong sappy shoots do not furnish the fruit. The new growths must be well thinned and freely exposed. Trees that are only slightly injured should now be pruned, lightly cutting out dead wood and naked branches. By this means the centre of the trees is kept well furnished with young fruiting wood, and there is less loss in severe seasons. I do not advise laying in much sucker growth, but hard, firm shoots which spring from the leading branches. In training keep the trees close up to the walls. It is well to restrict the leaders to a certain space, as they bear little fruit when not kept in check. The Fig produces so much weed annually that there is little difficulty in laying in plenty of good wood close to the main stems, and as the fruits are produced on the points of last year's growth, sufficient of this should be nailed in to furnish a crop.

G. WYTHES.

### ORCHIDS.

#### SEASONABLE NOTES ON ORCHIDS.

WE are now commencing the growing season for Orchids, and increased supplies of moisture will be required both at the roots and in the atmosphere. The ventilation still requires the greatest care, as advised in previous notes. All shading should by this time be fixed, as the sun is now very powerful. This must not be let down except during the hottest part of bright days, raising it again about 2 o'clock at the latest, and closing the warm houses with plenty of moisture. Where cool Orchids are grown in a span-roofed structure running north and south, the shading must be right down until 3 o'clock or later according to the weather, keeping the day temperature as near 60° as possible. Among the many Orchids that require repotting or surfacing now will be the latest plants of *Laelia anceps*, also the spring-flowering *Dendrobis* as they go out of bloom. These latter should be kept in as small pots as possible, especially the deciduous group, as *D. Bensoniæ* and *D. crassinode*. After potting, water must be judiciously applied, or the young shoots will be apt to damp off. Sudden exposure to strong sunlight is also very injurious to these after being repotted, as however carefully done, it is to a certain extent harmful by checking the progress of the roots. *Lycastes*, *Zygopetalums*, *Oncidiums* of the *Marshallianum* type, and any plants in the cool house that are not in good order at the roots may now be attended to; also many *Cattleyas*, as *Trianeæ*, *Percivaliana*, and all the late autumn flowering

species. Where there are many, such as *Miltonia vexillaria*, *Masdevallias*, or any of the *Oncidiums* with long branching panicles, coming into flower, it may be found necessary to fumigate these lightly for a couple of evenings in succession in case of thrips, green-fly, or other insects being numerous. They should be arranged in one house, as many as practicable, and must be shaded early the following morning if bright, and if time can be found to do so, carefully sponged after the last fumigation. The state of growth must be the guide to watering, *Pleiones* or *Calanthes* newly potted requiring very little. *Cymbidiums* in flower or growing freely need abundance, and as the spikes appear in *Odontoglossum citrosmum*, the plants be well soaked in a pail or tank to moisten every part of the compost, thus plumping up the wasted-looking pseudo-bulbs and enabling them to produce good healthy spikes. As the atmospheric moisture is increased, greater care will be necessary in keeping the flowers, those of *Cattleya Skinneri*, *C. Mendeli*, and others being easily spotted. If there is no flowering house, all plants in blossom should be grouped in prominent positions in the respective houses and less water sprinkled upon the stages, floors, &c., near them. A little more shade is also a great advantage.

I have never had so little trouble with woodlice and small snails in the houses as during this spring, and this I attribute to the introduction of a few French frogs. They are frequently to be seen at night, more especially in and about the plants, where, owing to their greater size and weight, our English toads—useful as they are—could not get. Continue to maintain a sweet atmosphere in the houses by frequent cleaning of the pots, stages and floors, removing all decayed leaves, spent pseudo-bulbs or anything that tends to make the plants look untidy. Any *Cattleyas* or similar Orchids not repotted should, if necessary, be freshly tied up and new stakes given where required. A minimum temperature for the East India house will now be 60° at night, running up to 70° on dull days, 75° to 80° by sun heat. For the *Cattleyas* 55° at night is ample, 65° by day, allowing the temperature to rise gradually and ventilating freely on hot days. The cool house may range between 50° and 60° according to the outside temperature, not exceeding the latter figure excepting on very hot days. H. R.

**Cypripedium Zeus.**—This very pretty and distinct hybrid is now flowering in the collection of Mr. R. J. Measures at Cambridge Lodge, Camberwell. It is a cross between *C. callosum* and *C. ciliolare*. The flower is of fine proportions and prettily marked, the dorsal sepal large, white, veined in the centre with pale green and on each side with rose: the petals broad and gracefully drooping, spotted with blackish spots, and densely dotted at the base. The pouch resembles very much in shape that of *C. Curtisi*, but is not quite so deep in colour. The bloom is borne well up upon a long stem, which rises from nice clearly tessellated foliage.—W.

**Dendrobium Brymerianum.**—This fine species is deservedly popular and a favourite wherever grown. The beautifully fringed lip has a very striking and unusual appearance, and the bright golden colour is most attractive. *D. Brymerianum* is a medium grower, and has somewhat fusiform stems about 15 inches high, bearing upon the upper portions persistent green leaves. The roots are large and rather fleshy in texture, and the compost should for this reason be used in a rough and open condition, good lumps of charcoal being freely intermixed with the *Sphagnum* and peat. It should be grown in a hot moist house, and during this season must be plentifully supplied with water at the root. After the growth is

finished I find it rests better if kept rather drier than the evergreen section generally, but not sufficiently so to distress the plants. A minimum temperature of 50° is low enough for it during the winter, but 5° less will do no harm provided it is not accompanied by much atmospheric moisture. It usually blooms upon the two-year-old growths, and if well ripened in autumn the flowers are fairly plentifully produced in short racemes of about 3 inches each, chiefly towards the top of the pseudo-bulbs. Young plants raised from the growths that are often produced from the tops grow freely, and soon make flowering plants, as soon in fact as they attain a height of about 6 inches. A small growing variety of this Orchid sometimes appears among importations, but is quite worthless as a flowering plant, and only to be tolerated as a botanical curiosity on account of the flowers being self-fertilising, a fact proved by their fading and the ovary swelling before they are properly open. The type was introduced from Burmah in 1874, and named in compliment to Mr. W. Brymer, of Dorchester.—H. R.

**Dendrobium Wardianum** (Broome's variety).—A flower of this magnificent variety comes from Mr. Broome, of Llandudno. It is very large, of good form, and richly coloured. The sepals are bright rosy magenta on the outer surface, which distinctly shows through on the inner side, each having a distinct clear white margin, heavily tipped with crimson-magenta; the petals are broader than the sepals, pure white, and also tipped with crimson-magenta, whilst the fine large lip is recurved at the apex, and also has a large blotch of the crimson-magenta colour—a clear white zone running between that and the bright orange-yellow throat, the two dark maroon eye-like spots at the base being very prominent. This is certainly a grand variety, and is said to be more after the typical form, but more highly coloured.—W.

#### CATCLEYA ACLANDIE.

UNFORTUNATELY, this lovely little Orchid is not frequently seen in good condition, and although a little more difficult to grow than the larger habited species, it will, in skilful hands, be usually satisfactory. A frequent cause of failure with this kind is allowing the flowers to remain upon the plants too long, thus wasting their energies; and when, as often happens, the plants bloom twice in the year the evil is intensified. From a week to ten days is quite long enough to leave the flowers on the plants, and if then cut and placed in water they last fully as long. Many cultivators prefer the block system for *C. Aclandie*, and there is much to be said in its favour, as nothing can possibly surfeit the roots or cause them to decay prematurely. The plants must, however, have the best attention under this treatment and never be allowed to suffer from want of water, or they quickly become shrivelled and weakened. This is, perhaps, even more to be guarded against in winter than during the growing season, as the atmosphere is so much drier. I was reminded of this recently by a plant in a small collection in the neighbourhood. This had evidently been imported about two years and had made good progress on the block, the roots running from end to end of it showing how they had enjoyed the atmosphere provided for them while growing. The pseudo-bulbs were, however, in a sad state, being shrivelled almost to the vanishing point, and this entirely owing to the want of water, as the plant had flowered but once and the blossoms had not been allowed to remain on very long. With cultivation of this careless order the plant would have been much safer in a small basket or pan with peat and *Sphagnum*, but if a little thought had been exercised, it would have been different. The pseudo-bulbs need only have been kept plump by due attention to watering, and there would then have been strong, healthy buds pushing, instead of weak, flowerless, and puny growths. Thus it will be seen that it is not so much the receptacle in which the plants are grown as the treatment they receive that is essential to success. The

species in question delights in a warm, moist atmosphere and a light position while growing, more especially at the latter end of the season. If grown in pots or baskets, these, as indicated above, should be small, as it dislikes a large body of compost about its roots. It is a small-growing kind, not usually more than 5 inches high, the pseudo-bulbs slender, and bearing a pair of oval, deep green leaves. When compared with the size of the plant, the flowers are very large, frequently from 3½ inches to 4 inches across; the colour varies from dull green to brown on the sepals and petals, which are spotted and streaked with yellow and purple. The lip also varies in colour, is spreading in front, narrower at the base, and, unlike the majority of the genus, does not fold over the column. *C. Aclandie* is a native of Brazil, whence it was introduced in 1839. It usually flowers in June, but, as mentioned above, it sometimes produces a second lot of flowering growths.

R.

#### SMALL-GROWING VANDAS.

The genus *Vanda* includes some of the finest and most stately Orchids ever introduced, having not only remarkably beautiful flowers, but handsome evergreen leaves, and therefore very ornamental throughout the whole year. Being plants which come from a very hot quarter of the globe, they naturally require strong heat under cultivation, and this, with the large dimensions that some of the kinds attain, do not admit of their being generally grown. There are, however, some of very dwarf habit which should find a place in every collection. During recent years some beautiful additions have been made to these small growing kinds which succeed admirably in quite a cool temperature. For these dwarf *Vandas* baskets are preferable to either pots or cylinders, as it is very essential that they should have all the light possible; in fact, they require only to be shaded when the sun is very powerful and the foliage is in danger of being scorched. The baskets should be suspended close to the roof and about two-thirds filled with drainage, the remaining portion being living *Sphagnum Moss*, which should be renewed annually, or when not in a sweet condition. During the summer and growing season water should be freely supplied and the atmosphere kept well charged with moisture, at which season the temperature may rise to 80°, but during the winter much less moisture, both at the roots and in the atmosphere, will be required, the thermometer not being allowed to descend lower than about 55° or 60°, excepting for *V. Amesiana* and *V. Kimballiana*. These two kinds I have grown in quite a cool temperature, and they flower much better than when placed in heat. It was in 1819 that the first *Vanda* flowered in this country in the collection of Sir Joseph Banks. This was *V. Roxburghi*, upon which the genus was founded by Robert Brown.

**V. ROXBURGHII.**—This plant grows about 18 inches to 2 feet high, the stem being furnished with broad, curved, leathery leaves, each about 6 inches in length. The flowers, which are produced during the summer months, are borne upon ascending racemes, which usually carry from six to nine blossoms. The sepals and petals are pale green, with chequered lines of olive-brown, the outer surfaces being clear white; the lip deep violet-blue with small white side lobes. Among some of the plants sent home a variety which has the lip of a bright rosy red has appeared. This species is very plentiful in Bengal and other parts of India.

**V. CERULEA.**—A very valuable addition to this family, as the blooms are of the rare blue which is so seldom found in plants. This plant cannot compare with the large-growing blue kind (*V. cerulea*), but it is, nevertheless, an equally

desirable plant. It produces strap-shaped leaves upon an elongated stem, and usually flowers during the early summer months, the erect slender scape usually carrying over a dozen of these charming blossoms. The sepals and petals are of a pale mauve-blue, whilst the lip is rich violet. This little gem was first discovered in Upper Burmah in 1837, but was not introduced for thirty years later, when it was sent home from the Arracan Mountains, where it grows at considerably over 1000 feet elevation. There are several fine varieties of this plant.

**V. AMESIANA.**—This is also a native of Upper Burmah, and has only been introduced about six or seven years. It was first discovered by Mr. Boxall in the Shan States, where it grows upon the mountains at an altitude where hoar frosts appear during the resting season. The plant is of a stiff dwarf habit, the leaves, which are upwards of a foot in length, tapering to a point. The flowers are borne in large quantities upon erect stems, and have white sepals and petals flushed with delicate rose, whilst the lip is of a rich magenta. There is also a white variety, both of which are very desirable, as the flowers appear in the winter months.

**V. BENSONI.**—This is another small-growing kind which has been grown in our gardens for many years, and forms a pleasing companion to *V. cerulescens* and its varieties alluded to above. The sepals and petals are yellowish and reticulated with bright brown, and the lip is of a light rosy purple. It first flowered with Messrs. Veitch and Sons, of Chelsea, over twenty years ago, and as it is found in the warmest parts of Burmah a little warmer temperature will suit it best under cultivation.

**V. DENISONIANA.**—This is an exceedingly pretty little kind, which was discovered by Col. Benson growing on the Arracan Mountains at an elevation of over 2000 feet. The leaves are each from 6 inches to a foot in length, and the raceme is usually shorter than the foliage and few-flowered. These, however, are upwards of 3 inches in diameter, and very distinct from those of all other kinds, being of clear ivory white in the sepals and petals, the lip even purer white. A very charming variety of this beautiful *Vanda* appeared amongst an importation of Messrs. B. S. Williams, of Holloway, about ten years ago, and which was named *V. Denisoniana hebraica*, in which the sepals and petals are sulphur-yellow with transverse bars and spotted. This, however, appears to be a very rare plant.

**V. KIMBALLIANA.**—Another recent addition found by Mr. Boxall at the same time as *V. Amesiana*, and introduced by Messrs. Low and Co., of Clapton. It is one of the most beautiful of all the small growing kinds, and, like its companion, is especially adapted for amateurs who have not the convenience and strong heat necessary for many of the larger species. It is of very dwarf habit with narrow leaves, and produces a spike of from six to a dozen blooms, which are individually nearly 2 inches across. The sepals and petals are pure white, the latter prettily twisted, and the lip of a rich clear bright purple.

There are also a few other kinds which might be included in this list, but these alone would form a very lovely collection.

WM. HUGH GOWER.

**Dendrobium japonicum.**—This is a pretty little plant that one seldom meets with, and although it is not one of the most showy species in this family, it is decidedly worthy of attention and a welcome addition to our coolhouse kinds. The stems, which grow from 6 inches to 1 foot in length, are slender and deciduous; the flowers are each about  $1\frac{1}{2}$  inches in diameter, the sepals and petals white when first open, becoming flushed with age; the lip is recurved, also white, with a few purplish dots at the base. This plant has been in cultivation for about thirty-five years, having been sent from Japan to the Royal Gardens, Kew. It was, however, known many years previously, for we

find it described by Dr. Lindley in his "Genera and Species of Orchidaceous Plants" in 1831. A very pretty specimen of this dwarf-growing plant is now flowering with Messrs. J. Laing and Sons at Forest Hill.—W.

## TREES AND SHRUBS.

### SPIRÆA LINDLEYANA.

THERE is a small group of shrubby *Spiræas* remarkable for their pinnate leaves, and of these by far the best known as well as the largest is that here illustrated—*S. Lindleyana*—which will reach a height of from 12 feet to 15 feet, and even higher. It pushes up suckers freely, so that when occupying an isolated position it usually forms a broad pyramidal mass or clump well furnished with its beautiful pinnate leaves. From this circumstance it forms a really handsome object out of flower, but when laden with its large branching panicles of white flowers, as herein shown, its beauty is, of course,

*Spiræa Lindleyana.* Engraved for THE GARDEN from a photograph sent by Miss Bird, Esher.

greatly enhanced. This *Spiræa* is specially valuable from the fact that it is the last of the genus to unfold its blossoms, though some of the others may produce secondary blooms even after this is past. *S. Lindleyana* is, as a rule, at its best in August, though in some years it may commence to flower in July, and I have also noted it in good condition in September. Should the winter be mild the leaves are retained for long time. Though this *Spiræa* is seen at its best when standing singly, yet where associated with other shrubs and ample space allowed for its development, it forms a very imposing feature. Another pinnate-leaved species is the Siberian *S. sorbifolia*, which usually reaches a height of about 4 feet to 5 feet. It blooms earlier than *S. Lindleyana*, and is wanting in the grace and elegance of that species. In his monograph of the *Spiræas* M. Maximowicz places the pinnate-leaved species by themselves under the generic name of *Sorbaria*. T.

**Bambusa Metake and the frost.**—It is pleasing to find how well this Bamboo has stood the late wintry weather. We have here large clumps of it growing freely by the side of a small

lake. These do not exhibit the slightest sign of having passed through 28° of frost. Fortunately, the clumps in question were not exposed to keen, cutting winds, which are more injurious to Bamboos than severe frost. It would be difficult to find a more pleasing and suitable subject for waterside planting than this Bamboo, which grows luxuriantly in any ordinary garden soil.—E. M.

**Robinia hispida.**—The French journal *Le Jardin* for March 5 contains a most interesting article on "Shrubs for Forcing," and quotes a long list of flowering shrubs that were exhibited by Messrs. Moser, of Versailles, at the Concours Général Agricole de Paris, held in the month of February. Among those that are rarely seen so treated in this country occurs the name of *Robinia hispida*, which would be certainly very distinct from any of its associates. The only other leguminous plant whose name appears in the list in question is *Wistaria sinensis*, or *Glycine sinensis*, as our French neighbours often prefer to call it. According to Messrs. Moser, both the *Robinia* and the *Wistaria* give better results if they are grown in pots a year before they are forced than they do if lifted in the autumn, potted and taken under cover for forcing in the coming spring.

The Laburnum also generally does best if subjected to the same kind of treatment. The bulk of the exhibit consisted of Azaleas, Rhododendrons, Lilacs and Magnolias, as well as *Staphylea colchica*, *Andromeda japonica* and the pretty little *Erica carnea* or herbacea and its white variety. Messrs. Moser also contribute a list of subjects suitable for forcing other than those exhibited by them, but all those mentioned are used in this country for the same purpose, the most uncommon of the whole being *Xanthoceras sorbifolia*, whose spikes of white blossoms with their peculiar coppery blotch are very distinct from anything else.—H. P.

**Evergreen Euonymus.**—One of the most generally grown shrubs of an evergreen character that we have in our gardens is the Japanese *Euonymus*, of which immense numbers are sold every year by our nurserymen. Several causes combine to render it popular, as in the first place it can be easily and quickly propagated by means of cuttings; next, the young plants grow freely, and with a little attention it forms a neat bush, while owing to the dense mass of roots it can be lifted at almost any season of the year with little or no injury. Added to all this is the fact that it is a first-rate subject for planting in proximity to the sea, and one of the best Evergreens we have for towns and smoky districts. Just now in many

places, owing to the frost, its claim to be regarded as an Evergreen does not rank high, as most of the leaves are quite dead, while the shoots are killed back for some distance. The destruction is by no means uniform, as some plants have suffered much more than others, even when separated by but a few yards. This *Euonymus*, however, quickly recovers, so that plants which just now present a sorry spectacle will in many cases within a few months show little or no trace of the ordeal through which they have passed. As might be supposed, the variegated-leaved varieties have in most instances suffered a good deal more than the ordinary green-leaved form, while the little neat-growing variety *microphyllus* has been hard hit. The close habit of this, combined with its deep green foliage, renders it a very popular Evergreen for window boxes and similar purposes during mild winters, but an occasional severe one like this has been will kill great numbers of it, and very few will be seen for a year or two. The rambling growing *Euonymus radicans* with its variegated-leaved variety has not suffered nearly so much as its larger relative, for in the case of *E. radicans* there is in most instances but little damage done, and, except some browned leaves, the plants bear but little traces of the winter they have just passed through. A distinct variety of *E. radicans* known as *Carrieri* seems to be even less injured than the type.—T.

**Cunninghamia sinensis.**—This, better known perhaps as *Cunninghamia lanceolata*, is an exotic that has utterly failed to justify the expectations formed as to the position it was likely to occupy in English gardens, as some little time after its introduction in 1804 it was planted rather freely in many places that had the reputation in those days of attempting to naturalise novelties. When I took charge of the gardens here, some thirteen years ago, I found four specimens of this *Cunninghamia* in various parts of the pleasure grounds. Two of these were in such indifferent health, dead branches decidedly predominating, that their removal was at once effected, another was slightly better, but a *Deodar Cedar* had been planted too close, and a branch of the latter tree coming away rather more horizontally than usual had hopelessly crippled and disfigured the leader of the *Cunninghamia*; the remaining tree was and is a very fair specimen of its class. This for some years had not had very good treatment, a lot of big *ponticum Rhododendrons* being allowed to grow into it on two sides. These were cut hard away, and the tree is now fairly well furnished on all sides and is nearly 25 feet high. A drawback to the tree is the brown decaying appearance of the foliage, a result apparently the work of winter frosts. Cutting winds have a similar effect on the foliage, and the planter of the tree was evidently aware of this fact, for it is in a very sheltered spot. I have been led to furnish the foregoing particulars from the fact that inquiries are often made respecting this tree and the advice sometimes given to give it a place in the flower garden or pleasure ground, but from my experience with it here I cannot agree with this. I should never find room for another *Cunninghamia*. It is a pity that it is not satisfactory, as appearances would seem to indicate that, given a suitable climate, it would make a very handsome tree; the foliage not affected by the weather is of a bright pleasing green, and the general habit tends towards building up a well furnished specimen, at the same time lacking the excessive stiffness and formality that are characteristic of many of the coniferae.—E. BURRELL, *Claremont*.

**Death of Evergreens.**—It is sad to walk just now through some of our small towns and see all the little gardens in mourning owing to dead Evergreens. It shows well the thoughtless waste that goes on in continually planting in our country Evergreens which are quite unable to support hard weather away from sheltered places near the sea shore. The fact that they escape in mild winters makes them all the more ready for the frost when it does come. Some of our Evergreens that are common, like the Laurel and the Portugal

Laurel, grow so rapidly, are so easily raised in nurseries, and look so glossy, everybody plants them, but in any thoughtful way of planting, things that are periodically killed should not be planted. There are several things which are so hardy as not to perish in such cases, such as the Yew, Holly, several of the Pines besides the Scotch Pine, and Box, which is very beautiful when well grown. It is also a great mistake not to trust more to summer leafing trees, which are mostly much hardier than the Evergreens. Between the conifers and the common Evergreens there has hardly been a place left in gardens for the many beautiful things of Europe and America which are quite hardy, and which go to rest in winter as our Oaks and Birches do. In any case a fine live Cocks-pur Thorn is better than a dead Evergreen, and we are not sorry for the deaths of the millions of Evergreens so thoughtlessly planted. They cast a gloom and a monotony over pleasure grounds, which is death to the variety and beauty that are so easily attained if we do not give ourselves over to the nursery mixture of things with little merit save that of rapid growth, followed, however, in hard winters by a still more rapid death.—*Fidd.*

THE BEST OF THE PINE TRIBE.

A FEW tree-loving friends lately talked after dinner about the large number of useless conifers, such as the Wellingtonia, Araucaria and many other half-hardy things, which, however good in their own countries, are poor and useless in ours. After deploring the great waste of money and good ground caused by planting some of these trees and the resulting ugliness, we endeavoured to elicit opinions as to which among the many conifers introduced to this country were really worth planting. There were only about twenty thought good enough, from a woodland point of view, to be exempted from the general condemnation passed upon conifers. We enumerate them:—

- |   |   |
|---|---|
| 1. Silver Fir ( <i>Abies pectinata</i> )              | 11. <i>Thuopsis borealis</i>                        |
| 2. Corsican Pine ( <i>Pinus Laricio</i> )             | 12. <i>Cupressus Lawsoniana</i>                     |
| 3. Cedar of Lebanon ( <i>Cedrus Libani</i> )          | 13. <i>Taxodium distichum</i>                       |
| 4. White Pine ( <i>Pinus Strobus</i> )                | 14. The Pineaster ( <i>Pinus Pinaster</i> )         |
| 5. Swiss Pine ( <i>Pinus Combra</i> )                 | 15. Colorado Douglas Fir ( <i>Abies Douglasii</i> ) |
| 6. Larch  | 16. <i>Abies nobilis</i>                            |
| 7. Black Spruce ( <i>Picea nigra</i> )                | 17. Nordmann's Fir ( <i>Abies Nordmanniana</i> )    |
| 8. Austrian Pine                                      | 18. The Bhotan Pine ( <i>Pinus excelsa</i> )        |
| 9. The Rocky Mountain Spruce ( <i>Picea pungens</i> ) | 19. <i>Abies brachyphylla</i>                       |
| 10. <i>Picea concolor</i>                             | 20. <i>Pinus monticola</i>                          |
|   | 21. <i>Tsuga Mertensiana</i>                        |
|   | 22. <i>Thuja Lobbi</i>                              |
|   | 23. <i>Picea orientalis</i>                         |

A great many of the introduced Pine and Fir tribe do well in some parts and not in others. Some do best north, some south, some in valleys, some on hills, some on one soil and some on another. We omit the common Spruce, as it is such a miserable failure in many soils.

THE FORESTS OF THE WABASH VALLEY.

THE composition of the remarkable forests which, in spite of the terrible inroads that have been made in them during the last twenty-five years, still cover considerable portions of the region in Southern Illinois and Indiana watered by the Wabash River and its tributaries was first made known by a paper published in 1882 in the fifth volume of the "Proceedings of the United States National Museum" by Dr. Robert Ridgway, the ornithologist of the Smithsonian Institution.

Dr. Ridgway was born in Mount Carmel, on the banks of the Wabash River, nearly opposite the mouth of White River, and his early work brought him into familiar

intercourse with the trees of that region. By a piece of good fortune his investigations have, moreover, been supplemented by those of another naturalist—Dr. Jacob Schneck—who for many years has lived in Mount Carmel and has also been specially interested in trees. The result of this fortunate association has been that the forests in the neighbourhood of the mouth of White River have been more carefully studied than those in any other spot of equal interest west of the Alleghany Mountains.

In a second paper on the Wabash Silva, recently published in the seventeenth volume of the "Proceedings of the National Museum," Professor Ridgway shows that the number of indigenous arborescent species in the Wabash valley south of the mouth of White River is 107, or more than a quarter of all the arborescent species in North America north of Mexico; and even this number can be slightly increased, as one or two species of *Crataegus*, overlooked by Professor Ridgway, grow near Mount Carmel. Some idea of the surprising richness of the forest flora in this region can be obtained by an examination of Dr. Ridgway's list of trees growing on restricted areas. On a tract of 75 acres he found fifty-four species of trees, and another of 22 acres contained forty-three species. On a tract of 40 acres one mile south-east of Olney, in Richland County, Illinois, what the author modestly calls an imperfect survey of the woods shows thirty-six species. The nearest approach to such a concentration of tree species in a restricted area is in Central Yezo, where Professor Sargent found sixty-two species and varieties of trees growing in the immediate neighbourhood of Sapporo at practically one level above the sea. The height attained by these Wabash valley trees is as remarkable as the number of species in the forest. Individuals of forty-two species reach a height of 100 feet, and those of twenty-one species grow to the height of 130 feet. Individuals 150 feet high of thirteen of these species have been measured. A specimen of *Quercus texana*, called *Quercus coccinea* by Dr. Ridgway, the tallest of the Wabash Oaks, and perhaps the tallest Oak in North America, measured 180 feet and a Tulip tree 190 feet; a Pecan, the tallest Hickory, 175 feet; a Cottonwood (*Populus monilifera*), 170 feet; a Bur Oak (*Quercus macrocarpa*), 165 feet; while, in addition to the trees already mentioned, a Liquidambar and a Black Oak attained a height of 160 feet. The size of the trunks of some of these trees, measured at 3 feet above the surface of the ground, is hardly less remarkable than their height. A Sycamore (*Platanus occidentalis*) girthed 33½ feet, a Tulip tree 25 feet, a White Oak 22 feet, a Black Walnut 22 feet, a Black Oak 20 feet, and a Texas Oak 20 feet. In comparison with such trees, the inhabitants of Eastern forests, where trees 100 feet tall are extremely rare, appear like pigmies, and persons familiar only with forests of the Atlantic seaboard can form no idea of the magnificence of these trees.

This region is the home of some of our most beautiful and valuable trees. On the bottom-lands of the rivers the Pecan and the great western Hickory (*Hicoria laciniosa*) grow with all the Swamp White Oaks, the Pin Oak, the Texas Oak, and that remarkable form of the Spanish Oak, which, usually an upland tree, sends up on these bottom-lands a tall, beautiful shaft covered with pale bark, which might readily be mistaken for the trunk of one of the White Oaks. The attention is first called to this variety in Professor Ridgway's second paper, although it has long been known to southern lumbermen. Common in the Yazoo delta and in Eastern Arkansas, and not rare in

Northern Alabama and Western Florida, it is valued as a timber tree, and is said to produce wood equal to that of the White Oak. In the Wabash valley the southern Cypress (*Taxodium*), the Water Hickory, the Water Loenst, and the Planer Tree, all denizens of the south, find their northern homes, and there the rare Swamp Cottonwood grows to its largest size, and the Catalpa displays its greatest beauty. In these lowland forests great lianes festoon the trees, and Dr. Ridgway tells us of Grape Vines with stems more than 100 feet long and more than a foot in diameter, and of *Aristolochias*, Poison Ivies, and *Bignonias* nearly as large. No other American forest scene is more beautiful, and certainly no other forest of deciduous trees, for it must be remembered that in all this great collection of trees there is not a single species with evergreen leaves, is more interesting.—*Garden and Forest*.

## STOVE AND GREENHOUSE.

### THE CAPE PRIMROSES.

(STREPTOCARPI.)

THESE *Gesnera*-like plants are of quite recent introduction if we except *S. biflorus*, this having been raised a dozen years or so back. Presumably, *S. biflorus*, the parentage of which does not appear to be fully recorded, has had considerable influence in these later hybrids, which originated at Kew, and which hybrids have been taken in hand by Messrs. Veitch and Sons at Chelsea, the result being a still further advancement in the diversity of colours, as well as in the flowering of the plants themselves. Some ten years or so back I was struck with the utility of *S. biflorus* as a small decorative pot plant, and I took it in hand for that purpose with very satisfactory results. The style of its flowering is denoted in its name. This has been greatly improved upon, however, in the present-day hybrids as raised and grown at Chelsea; so much, in fact, as to make the plants extremely effective for months together, the same spike producing many flowers, whilst the production of spikes is more continuous also.

Many growers have taken the cultivation of these beautiful plants in hand with varied results. Where a partial failure has occurred it is in nearly every instance to be attributed to growing the plants in too much heat and moisture. This they do not require, nor will it be found so satisfactory when attempted. True, it is desirable, and, in fact, essential, to raise seedlings in warmth the same as one would *Gloxinias*; but as soon as these seedlings are once well established then the treatment should be on different lines. Compared with *Gesneras* and *Gloxinias*—to which the *Streptocarpus* is closely allied—less heat and moisture too are necessary, otherwise the constitution of the plants will be greatly impaired. Less shading, also, when once established will be productive of better results. The best plants I have seen were being grown in a mixed collection of flowering subjects in a cool greenhouse, the other occupants being tuberous *Begonias*, small *Geraniums*, *Petunias*, &c., during the month of July in the north of England. Another good lot of plants were finding a congenial sphere in a Peach house, the fruit from which had all been gathered, this fact denoting the treatment then accorded to such a house. In order to have the plants in flower early—say during April and May—a slight amount of warmth must be given, as in the case of the tuberous *Begonia*; but in doing this endeavour to select a posi-

tion with a fair amount of ventilation and near to the glass also, with no shade from other plants. These beautiful plants have given good results as window subjects, lasting in such positions a long time in flower. One other important fact to be borne in mind is that of not keeping the plants absolutely dry at the roots during the winter; this, too, will conduce to failure, being very weakening to the growth, for it must be borne in mind that although a somewhat fleshy stem is produced beneath the soil, it cannot be designated a tuber or bulb, hence it will not withstand drought in the same measure. There is a use to which these hybrid *Streptocarpi* may be turned, but of which not sufficient advantage has thus far been taken. It is that of planting out well-established plants as marginal lines to cool conservatory borders. At Kew they are grown thus with very marked success in the succulent house, but a cooler house would answer quite as well provided there be no great amount of shade. No large

in the colours to what there was only a few years back, the range of colour being greater, whilst in the markings there is a decided advance. In point of size also the same improvement is apparent. The accompanying illustration from a photograph shows the freedom of flowering now characterising these hybrids; the purity of colour in this instance is also very clear. *Streptocarpus Wendlandi* is an imported species of very remarkable growth, with an erect flower-spike bearing a number of flowers. Allusion is made to this species, as it is the most recent one to which a first-class certificate was awarded. It is totally distinct from the preceding hybrids. SOUTHRON.

**Lachenalias in baskets.**—For years I have grown *Lachenalia tricolor* in baskets with excellent results. I consider that in no other way do *Lachenalias* give such interesting results. Our plants from the time they commence to grow are suspended from the rafters of a three-quarter

*Streptocarpus hybrids.* Engraved for THE GARDEN from a photograph of plants growing in the garden of Mr. E. H. Lushington, Brockenhurst, Cobham.

quantity of soil is needed for this purpose, nor should it be of too rich a character, a more important feature being to keep it firm around the plants.

Where no stock at present exists, seed if sown at once will yield plants that will flower next autumn in small pots; these another season will be large enough for all practical purposes, for nothing beyond a 6-inch or 7-inch pot at the most is needed for this dwarf section. The seed germinates somewhat slowly compared with those of *Gloxinias*, but in abundance. The seedlings should be pricked off into pans as soon as they can be conveniently handled in a light and sandy soil. Later on this can again be done into shallow boxes, so as to save room. Another capital plan is to plant out in cold pits towards the end of May near the glass with a slight bottom-heat to encourage growth at first; in this way quite large plants can be had by the autumn, when potting up should be performed rather than storing in other ways. There is now a vast improvement

span-roofed Peach house, where the constantly opened ventilators afford abundance of air. By inserting the bulbs rather thickly the wires of the baskets are not visible, as in the photograph, p. 163. Ordinary Moss I always use. The bulbs are placed a few inches apart, the point of each being just within the Moss. As "W." says, it is not necessary to disturb the bulbs every year; liquid manure will suffice to promote a vigorous growth.—E. M.

**Stephanotis floribunda.**—When on a visit recently to the nurseries of Messrs. Fisher, Son and Sibray, Handsworth, Sheffield, I noticed a very fine plant of the above climber. The house it was growing in was comparatively cool, being used for growing *Azaleas*, greenhouse *Rhododendrons*, and plants of a like description. It was planted out, and covered a roof space of 500 square feet at the least. The plant looked very healthy, and a much greater space could have been covered if it had been available. I was informed large quantities of wood are cut out every year in order to keep the plant sufficiently thin. One great advantage in growing this plant cool is that mealy bug is not so troublesome as when

grown in strong heat. The latter pest does not trouble the Handsworth specimen, but it requires sponging now and then to remove the sooty deposit that finds its way into the house. The plant blooms well every year, being at its best in August. Perhaps some of your readers would kindly inform me of the space covered by the largest known specimen *Stephanotis floribunda*.—C. R.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

MARCH 26.

THE improvement so manifest at the earlier meeting in the month was on this occasion further enhanced as regards the number and variety of the exhibits as well as in the attendance of Fellows. Orchids had again by far the greater monopoly in point of numbers and rarity, *Dendrobiums* more particularly being in the ascendant. Most notable amongst this genus was the prince of the *D. nobile* type, viz., *D. nobile nobiliss*, of which a grand plant was exhibited in profuse flower, the finest example by far that has yet been seen of this grand form. Other *Dendrobes*, chiefly hybrids, were shown in profusion, nearly every one of which bore evidence of affinity to *D. nobile*. Some wonderful forms of *Odontoglossums* came from The Dell collection, being superb varieties and most notable examples of good culture. The chief point of attraction, perhaps, from the point of rarity and singular structure was to be found in *Bulbophyllum burfordense*, a decided botanical acquisition. Some fine forms of *Cattleya Trianae* were shown; so also were others of *C. speciosissima*. *Vandas* also made their appearance from Holloway, and quite a unique plant was to be seen in *Bollea Schrederiana*, from St. Albans, the Orchid committee signifying their approval by a first-class certificate, the only one awarded on this occasion.

At this meeting in March, Hyacinths, Tulips, and Narcissi are nearly always a leading feature, it being just the right season for Hyacinths and early Tulips, but, singular to say, trade groups of these as usually seen were entirely absent. None of the abnormal examples of the Hyacinth, as in former years, from bulbs several years of age, were shown. A mixed collection of bulbs and other spring flowers came from Syon, amongst which particular note should be made of the straw-coloured French Hyacinth, a valuable acquisition for cutting, and of sprays of *Acacia* so well grown in these gardens. As at the previous meeting, the *Amaryllids* from Chelsea were a feature, the coveted award being gained. At the present time the improvement that is most notable in these hybrids is the more rounded contour of the flowers, thus giving a better shape; a manifest improvement in depth of colour is also gaining ground. *Camellias* from Waltham Cross, *Caladiums* from Roupell Park, and *Clivias* from the well-known Holloway collection were all to be seen in good condition. Last, but not least, the early spring-flowering hardy plants (bulbous and alpine) were shown in charming variety. The fruit and vegetable committee had but little before them, the report of which exhibits will be found under that head.

#### Orchid Committee.

A first-class certificate was made to—

*BOLLEA SCHREDERIANA*, of which quite a large specimen was shown, bearing nine fine flowers of large size and wax-like substance, the sepals and petals being of a clouded white and of incurved form, but not so much so as in the *Anguloas*. The labellum showed a faint tint of purple, fading with age, the flowers averaging 4 inches across. This is a decided acquisition to its genera. From Messrs. Sander and Co.

Awards of merit were accorded to—

*ODONTOGLOSSUM LUTEO-PURPUREUM AMPLISSIMUM*.—A very robust growing form of this species, with an unusually stout bulb and sturdy erect spike bearing eleven flowers. The spots and blotches were of a dark oak colour, with a straw-coloured base and tips, the lip being broad, yellowish white, with a pale oak-coloured blotch. From Mr. Weetman, Little Heywood.

*DENDROBIUM CORDELIA* (hybrid *D. euosmum leucopterum* × *D. aureum*).—A singularly distinct and beautiful form of dwarf growth, into the blooms of which more of the golden colour of *D. aureum* has been imparted than usually obtains by such a cross. The sepals and petals are transparent, white, flushed around the edges with faint rosy pink, the lip being veined with velvety crimson on a golden ground, having a margin of creamy-white. From Messrs. J. Veitch and Sons.

*CATLEYA TRIANA* (Parkes' var.).—A very fine form of robust growth and large flowers, into the sepals and petals of which has been infused a greater depth of the pervading tint, the lip being broader and more elongated, with the lower portion of a deep crimson-purple, the upper portion having a rich shading of old gold colour. From Mr. W. C. Parkes, Llanberis Tower, Tooting.

*CYPRIPEDIUM OLEUS* (hybrid *C. bellatulum* × *C. ciliolare*). This is quite a gem amongst the dwarf forms, in this respect taking more after *C. bellatulum*, as it does also in a great measure in its form, whilst the colour of its other parent has greatly prevailed. The petals are broad, vinous purple, with dark purple spots in profusion, the dorsal sepal being of the same shade in lines, with a trace of green, and the lip of a deep bronzy-purple. From Mr. R. J. Measures' collection.

*DENDROBIUM DONNESLE*.—A very fine variety, which is best described as *D. formosum giganteum* in growth with the flowers of *D. Jamesianum*, but of larger size. The petals are very broad, these and the sepals being of the purest transparent white, the lip having the deep orange blotch. From Mr. Bradshaw, The Grange, Southgate.

*DENDROBIUM SCHNEIDERIANUM* (hybrid *D. Findlayanum* × *D. aureum*).—An Orchid which has been previously shown, but not in such good condition as on this occasion (the plant in question was raised by Mr. Holmes). It has the expanded lip so prominent in *D. Findlayanum*, the entire flower being larger also; the lip is of a deep golden tint, with crimson veins in the centre, the sepals and petals being white, with a pale purple flush. From Mr. E. Ashworth, Wilmslow, Cheshire.

*DENDROBIUM SPLENDIDISSIMUM ILLUSTRIS* (hybrid *D. Leechianum* × *D. nobile nobiliss*), which is undoubtedly one of the finest forms of *D. splendidissimum* yet seen, a deeper infusion of the purple of its last-named parent being very manifest; the flowers are of extra size, whilst the deep vinous purple blotch on the lip is larger also, it being margined with pale sulphur and tipped with light purple. The growth is very free. It is a worthy companion to Cypher's hybrid shown at the previous meeting. From Mr. W. R. Lee, Auden-shaw, Manchester.

Botanical certificates were awarded to the following Orchids:—

*BULBOPHYLLUM BURFORDENSE* (previously alluded to) has much the largest flower of its genus, being yellowish green in colour, with a number of white spots; the plant in question also received a cultural commendation. From Sir Trevor Lawrence's collection.

*BATEMANIA PERUVIANA*.—A small, dwarf-growing species, with a short, dense spike of flowers, greenish yellow, with darker markings. From Messrs. Sander and Co.

*SCHOMBURGKIA UNULATA*, labelled *S. crispa*; whereas this latter var. has a white lip, that of the plant shown having the identical colour of *S. undulata* (a clear violet-purple), the sepals and petals undulated (not curled) and of a brownish purple shade. From Sir Trevor Lawrence.

*ODONTOGLOSSUM CRINITUM SAPHIRATUM*.—A form with light-coloured flowers of small proportions, but very light and pretty. From the same source as the last.

Medals were awarded as follows:—

To Mr. E. Ashworth for the remarkable specimen of *Dendrobium nobile nobiliss*, to which allusion has been made; the plant in question bore 389 flowers, the longest growth measuring 3 feet 9 inches, showing cultural skill of the highest excellence. Taking into consideration the short time this superior form of *D. nobile* has been in cultivation, it speaks well for the vigour of the plant to have attained such a size; its mass of richly coloured flowers produced a grand effect. Award silver Banksian medal.

To Messrs. J. Veitch and Sons for a handsome and choice group consisting largely of their own hybrids, amongst which there were no less than five plants of *Cymbidium eburneo-Lowianum* in rare condition and vigour. Another fine hybrid was *Cypridium macrochilum* of the *Selenipedium* group (*C. longifolium* × *C. caudatum* Linden), the beautifully marked inner part of the lip being very noteworthy. *C. Brysa*, another distinct hybrid, showed its affinity to *C. Seleni candidulum*, but with larger flowers, flushed with pale rosy pink. Another noteworthy hybrid was *Odontoglossum excellens*, raised between *O. triumphans* and *O. Pescatorei*, thus proving, what was already surmised, that the imported *O. excellens* was a hybrid of natural origin. *Epidendrum Endresio-Wallisi* was also shown, and *Dendrobium Cybele nobiliss* (*D. nobile nobiliss* - *D. Findlayanum*), having the sepals and petals of the first-named parent, with the form of lip of the latter, a dark blotch taking the place of the golden one. *D. Murrhinianum* has the features of *D. Ainsworthi* in a great measure, not showing much of *D. Wardianum*, one of its parents. Of other species there was a fine form of *Cymbidium Lowianum*, with extra dark crimson on the lip; *Odontoglossum crispum*, a handsome and beautiful form, the broad sepals and petals being entirely suffused with rosy purple, the golden colour of the lip deeper than usual; *Celoglyne crispa hololeuca* (alba), a good plant with ten spikes of bloom; *Cypridium Druryi*, with its golden flowers and dark lines on the sepals and petals; *Miltonia cuneata*, an uncommon species with a creamy white lip and the sepals and petals of a dark bronzy tint with traces of pale gold; *Oncidium superbiens*, a distinct species of the *O. macranthum* type; *Odontoglossum triumphans*, with two good spikes, and *O. Wilckenum*, a well-marked form; also *Dendrobium atroviolaceum* (awarded silver Flora medal).

Messrs. Sander and Co. sent a very choice assortment, amongst which there was a profusion of *Dendrobes*, chiefly hybrids of the best quality. *D. Owenianum*, a fine hybrid, showing some of the features of *D. melanodiscus*; *D. Ainsworthi*, a large and very superior form, with pure white sepals and petals; *D. nobile Cooksoni*, so very distinct, with the dark purple of the lip imparted also to the petals; *D. Findlayanum*, a fine mass in profuse flower, the well-expanded lip showing to good effect; *D. nobile Amesiae*, with clear, transparent white sepals and petals, the lip a trifle small in comparison, but richly marked; and *D. nobile Sanderi*, conspicuous by the absence of the dark blotch on the lip. Other good forms of *D. nobile* were also shown here. *Eulophelia Elizabethae* was also staged, as well as *Lycaste Skinneri*, of which there were several richly coloured varieties; *Pescatorea Lehmanni*, of a deeper colour than usual; and *Angreum Sanderianum*, always attractive with its charming spikes of white blossoms. *Cattleya Trianae alba* was shown in a cut state; also *C. Schrederiana alba*, the latter having the golden markings on the lip of a darker shade. *Lycaste Lawrenceana*, a somewhat uncommon species, was also shown here, and last, but decidedly not least, there was a very fine form of *Cypridium Lawrenceanum* *Hyeatum*, the plant having one large bloom; the species is clearly to be seen in the contour of the

flower, but all the purple has vanished, leaving given place to the purest white and dark green veins in the dorsal sepal, a lighter shade of green, nearly self-coloured, in the petals and in the pouch also, which is of a lighter shade still. Award silver Flora medal.

Messrs. B. S. Williams and Son sent a good group in which there were several capital plants of *Vanda snavis* and *V. tricolor*, the latter in variety, each plant bearing on the average two spikes. A fine specimen of *Cymbidium eburneum* was included with some twenty-four flowers; *Calanthe Sanderiana*, several plants in fresh condition; a good example of *Cypripedium Morganii* bearing several blooms; *C. Ashburtonia-expansum*, a fine form of one of the earlier hybrids; and *C. Masterianum*, a distinct variety; also *Angraecum Sanderianum* (syn., *A. modestum*), as well as *Dendrobium nobile Wallichianum*, *D. Lecchianum*, and several very healthy plants of *C. Chamberlainianum* with well marked flowers. Award silver Banksian medal.

From Messrs. H. Low and Co. came a very pleasing group, amongst which were several plants of *Odontoglossum (Miltonia) Rozeli* and its white variety in the healthiest possible condition with a great profusion of flowers of large size; a better lot of plants could not be desired. Other good things comprised *Cypripedium Curtii*, dark in colour; also *C. ciliolare*, *Cattleya Trianae*, *Odontoglossum triumphans*, richly marked; *O. Edwardsi*, *Oncidium luridum* and *O. Papilio*, as well as *Dendrobium Barberianum*. Award silver Banksian medal.

Messrs. Lewis and Co. had a small group comprising *Cattleya Trianae* in good vars., *Ada aurantiaca*, *Cymbidium Lowianum* and *Cypripedium cilo-villosum*, a distinct hybrid, with *Dendrobium cupillipes*, a charming dwarf species with rich golden-yellow flowers in two shades, and *D. primulinum*, one not often seen now (silver Banksian medal). Mr. James Cypher, Cheltenham, sent a splendidly grown lot of plants of *Dendrobiums*, comprising *D. crassinode* with bulb-wreathed in flowers, one plant bearing flowers of deeper colour than usual; *D. nobile pendulum*, a good old species in fine condition and full of bloom; *D. nobile pulcherrimum*, with long sepals and petals, slightly tipped with pale purple, the blotch on the lip of a deep maroon shade; *D. Ainsworthii*, a capital example; *D. nobile nobiliss.*, a sturdy plant, the flowers very deep in colour; *D. Wardianum giganteum*, with flowers 5 in. across the broad petals, the colouring being specially bright; *D. Wardianum album*, *D. nobile Statterianum*, with large blooms also, which, by reason of their size, assumed a drooping form, and other varieties in a cut state, also a plant of *Epidendrum xanthinum*, with blooms clustered at the apex of the spike, bright golden yellow in colour. Award silver Banksian medal.

Baron Schroeder sent a small, but exceedingly choice collection of cut blooms, amongst which were grand spikes of *Odontoglossum luteo-purpureum* (sixteen flowers), very rich in colour and of extra size, and *O. hystrix* (fourteen flowers), both being the very finest varieties. Another splendid example was a four-branched spike wreathed in bloom of *O. Leeanum*, somewhat in the way of *O. Andersonianum*, but larger and finer, having golden sepals and petals spotted and blotched with dull chocolate, the flowers bearing a rich aromatic perfume. Of *Cattleyas* there were *C. speciosissima Schroederiana* of large size, with sepals and petals of the purest white, the lip also white with bright purple veins continued into the throat, the margin of the throat bright yellow; also *C. Baroness Schroeder*, a most beautiful variety, rich in colour and of unusual size, the sepals and petals rosy mauve, the lip broad and deeply fringed with deep golden markings. *C. speciosissima* in another fine variety was included, with a rosy purple flush on the sepals and petals, and the lip of bright colouring; *Lelia vitellina*, with bright orange sepals and petals, singularly beautiful, the lip being brighter. *Epidendrum dollense* (hybrid), of which a dense spike was shown, has small orange-scarlet flowers

very bright. *Lycaste Skinneri* was represented by a deeply coloured form (awarded silver Banksian medal).

From Mr. W. C. Walker came *Cymbidium* sp., after *C. eburneum*, but with larger and more expanded flowers. From Mr. Vanner, Camden Wood, Chislehurst, came *Cypripedium Rothschildianum* (Vanner's var.), distinct in colour, the ground colour being lighter and the veinings darker, thus affording a greater contrast; one spike bore three large blooms; *C. Vanneri* (*C. selligerum majus* × *C. Curtisi*), a distinct-looking hybrid, the petals of which bore very minute spots in great profusion. Mr. Cayley, Leigham Court Road, Streatham, sent two remarkably well-grown plants of *Phaius grandiflorus*, each of which was only three years old; one bore nine spikes and 183 flowers and buds, and the other eight spikes and 143 flowers and buds, both being very noteworthy examples. From Mr. De Barri Crawley, Rosefield, Sevenoaks, came *Odontoglossum Andersonianum album*, pure white with dark crimson spots, a lovely variety; also *O. Ruckerianum Juno*, with a deep rosy purple flush on the sepals and petals, and a good form of *O. Coradinei*. Mr. Bradshaw had a very distinct variety of *O. crispum*, with very pale oak-coloured blotches and spots. From Mr. Ashworth came *Dendrobium nobile Ashworthii*, with pure white sepals and petals very faintly tipped with light purple; also *D. nobile Ashworthii*, after *D. nobile nobiliss.*, but with a lighter centre, the growth tall.

Sir Trevor Lawrence sent *Dendrobium Tattonianum*, with minute, but pretty flowers; also *Eulophia Elizabethae*, with a splendid spike of twenty-two blossoms and buds. *Vanda coerulescens* was represented by a cut spike, the colour of the sepals and petals a light mazarine-blue, the lip being dark blue; this is a choice species. *Dendrobium erucetum* and *Cymbidium ensifolium* came from the same source. From Mr. Weetman came *Dendrobium Weetmannianum*, a distinct form of *D. nobile*, somewhat after *D. nobile Ballianum*, with the purple shade brighter and a creamy margin to the lip. *Odontoglossum hystrix* came from the same source (a fine variety).

#### Floral Committee.

There were not many exhibits before this committee, and, owing to the lateness of the season, no Daffodils appeared in competition for the special prizes.

Awards of merit were granted to the following:—

**CLIVIA MODEL.**—A magnificent variety, showing a marked advance upon older kinds; the truss very large and the flowers of fine size, with broad rounded petals, in colour a rich orange-yellow. Exhibited by Messrs. B. S. Williams and Son, Upper Holloway.

**ANAKYLLIS GORGEOUS.**—The name of this new kind truly describes its beauty. It has a perfect shaped flower of a dark rich self-crimson colour, brilliant in effect. Shown by Messrs. J. Veitch and Sons, Chelsea.

**STREPTOCARPUS GRATS.**—This, the result of a cross between *S. Dunni* and the now popular hybrid strain, is a very good kind. The leaves are long and broad, the flowers most profuse in thick clusters, borne on stout erect stalks and of a deep rosy purple colour. This also came from Messrs. J. Veitch and Sons.

**MIGNONETTE BUSH HILL WHITE.**—This is certainly one of the whitest varieties of Mignonette we have yet seen, but the flower-spikes were rather thin and the scent decidedly weak. Shown by Messrs. H. Low & Sons, Clapton.

Miscellaneous contributions were varied and interesting. Messrs. B. S. Williams and Son exhibited a group of *Clivias* made up of splendid kinds. The best, besides the one above mentioned, were *Surprise*, light orange-red, with large truss; *Scarlet Gem*, bright deep red; *Holloway Beauty*, soft orange-red; *Mme. Van Houtte*, light orange-red; and *Ambrise Verschallet*. Japanese *Camellias* of varied shades, the flowers less stiff and formal than those of the older types, were included in this exhibit, to which a silver Banksian medal

was awarded. A fine group of *Caladiums* staged by Messrs. J. Peed and Sons, of Norwood, received a silver Flora medal. The plants were well grown and the colours of the leaves remarkably bright. Some of the best were *John Peed*, rich red in the centre of the leaf, shading to green on the edge; *L'Automne*, greenish white, the leaf large and self-coloured, except a few light purple markings; *Charlemagne*, a variety having enormous leaves, those shown 18 inches long, 14 inches wide, the leaf veins deep red, this colour mixed with white running over the leaf surface with dark green at the edge; *Prince of Wales*, deep red veins, distinct light green in the outer parts of the leaf; *Ernest Caille* and *Triomphe de Comte*. *Strobilanthes Dyerianus*, a beautiful foliage plant, was also well shown in its characteristic rich colour. The group of *Cinerarias* from Messrs. J. James and Son, Farnham Royal, represented this flower in the greatest possible perfection. The plants were dwarf, their pots hidden by luxuriant leafage, crowned with trusses of splendid flowers, remarkable alike for their size and rich purity of colour, self decidedly predominating. A silver Flora medal was awarded. *Camellias* from Messrs. W. Paul and Son, of Waltham Cross, were very fine indeed, and the magnificent exhibit of this new neglected, unpopular flower fully deserved the silver-gilt Flora medal awarded to it. Plants in flower and cut specimens were shown, including all the best of the older kinds and many besides, comparatively new, in lovely and varied shades of colour.

Hardy flowers were well shown by Mr. T. S. Ware, of Tottenham, who had a large and very varied group. Daffodils in the best trumpet and star-flowered kinds, *Hepaticas*, single and double red, white and blue forms, *Primula cashmeriana*, *P. rosca*, *P. denticulata* and its variety *alba*, *Saxifraga Bursariana*, *S. luteo-purpurea*, *Iris reticulata*, *Trillium grandiflorum*, *Sanguinaria canadensis*, *Snowflakes*, and *Solomon's Seal* were noteworthy in this group, which received a silver Flora medal. Messrs. Barr and Son also exhibited hardy flowers in interesting variety. Daffodils, cut specimens in many varieties, *Anemone fulgens*, *Iris reticulata*, *Saxifraga oppositifolia* in several fine forms, *Scillas*, *Hepaticas*, the double *Ficaria ranunculoides*, and the new early flowering *Tulipa violacea* were the chief things. A silver Banksian medal was awarded. A similar award was given to an effective group of flowering and fine-foliaged stove and greenhouse plants, arranged by Mr. G. Wythes, gardener to the Right Hon. Earl Percy, Syon House, Brentford. A splendid group of cut specimens of *Beaumontia grandiflora* came from Mr. Pitt, gardener to Earl Cowper, Panshanger, Herts. *Azalea pontica alba*, with flowers pure white except a yellow stain on two petals; *Clerodendron splendens*, an uncommon, but very beautiful tender climbing plant, producing large, many-flowered trusses of deep orange-red flowers, and *Veltheimia viridifolia* came from the same exhibitor. A silver Banksian medal was granted. Mr. H. B. May, of Upper Edmonton, sent a group of early-flowering *Clematises*, showing how readily they can be forced into bloom. Such varieties as *Mrs. Quilter*, with flowers of medium size and freely produced, are most attractive, and the plants shown, though young, were wreathed in blossoms. A bronze Banksian medal was awarded. Mr. R. Backhouse, Sutton Court, Hereford, exhibited a star *Narcissus* named *Dr. Fell*, having perianth segments of a pale cream colour and a clear rich yellow cup of unusual breadth.

#### Fruit Committee.

The exhibits before this committee were few in number, though interesting, only one collection of fruit being staged and three of vegetables. From Mr. G. Wythes, Syon House Gardens, Brentford, came a dish of *St. John's Fig*, this variety being shown by the same exhibitor at the previous meeting, thus indicating its good qualities as a variety for forcing in pots. The fruits sent on this occasion were of good size, the flesh

white and juicy. The same exhibitor sent a very nice lot of early Asparagus grown in permanent beds, which are forced yearly. A cultural award was given to this exhibit. The grass was excellent for the time of year, showing the value of this method of forcing Asparagus. Mr. P. Davidson, Iwerne House Gardens, Blandford, sent a dish of Tomatoes named Veitch's Perfection, a seedling from Ham Green and Perfection, the fruits being ribbed and well flavoured, but not considered by the committee superior to Ham Green. Mr. H. Balderson, Corner Hall, Hemel Hempstead, sent a dish of two varieties of Onions, Ailsa Craig and Rousham Park, Ailsa Craig being huge bulbs, but much decayed. The exhibitor stated that he had many similarly affected; whereas smaller, but well-grown Rousham Park were quite sound with the same culture and storage.

## NOTES OF THE WEEK.

**The late spring.**—Last year the old double yellow Daffodil began to bloom in the Grass on February 11. This year the first bloom opened March 22.—J. H. W. THOMAS.

**Sopronitis grandiflora.**—We have received from Mr. T. Bonsall, Elmet Hall Gardens, Leeds, a splendid flower of this Orchid, rich in colour and very broad, measuring more than 2½ inches across.

**Spiræa astilboides floribunda.**—This is one of the best of herbaceous Spiræas, the long feathery panicles of pure white flowers being more graceful than those of either *S. japonica* or *S. multiflora* compacta. It rivals *S. astilboides*, but the panicles are not so thickly set with flowers.—E. M.

**Crocus Sieberi.**—In THE GARDEN for March 23 *Crocus Imperati* and *C. biflorus* are specially noticed. I think *C. Sieberi* may also be mentioned as a very worthy and early-flowering species for growing in the grass. It has been strikingly charming here during the past week.—M. A. R., *Liphook*.

**Erica carnea.**—The brightest flower of the present week is this pretty Heath in gardens where it has been planted in broad sheets and spreading masses. It is as hardy as our native Heaths and a precious early flower which opens in the first genial days and remains a perfect glow of colour for many weeks. It is surprising that we do not see more of it.

**Scilla sibirica multiflora.**—A very fine form of the Siberian *Scilla* now flowering came from the Dutch growers under the above name, but it appears identical with that shown at the Drill Hall on Tuesday by Messrs. Barr named *S. sibirica taurica*. It is a fine variety, much earlier than the type and more robust, producing in great abundance long strong spikes of flowers somewhat paler in colour.

**Manure for Grass fields.**—In reference to the inquiry of "Hayling" as to the best manure for Grass fields, I would recommend him to try malt dust. This is a strong nitrogenous manure and very cheap. Its effects are marvellous on grass crops, Potatoes, Strawberries, &c. Now is the time to sow it and its good effects will be quickly visible. I have just had in a ton for my tennis lawns and small paddock. Sowing it is dirty work and the best way is to scatter it about carefully with a shovel.—EDWARD FISON, *Ipswich*.

**Damage to trees.**—We gather from the papers the following results of the severe gale. At Sandringham about 2000 trees were blown down, some of them of special historic interest, whilst on the adjacent Castle Rising estate the destruction was even greater. Some large old Elms have fallen in Windsor Park, and at Warwick great havoc was wrought among the trees, some of the fine Lebanon Cedars in the Castle grounds being uprooted, and the main roads to Warwick blocked by fallen trees. Around Rugby School 17 great Elms were blown down in less than an hour. In the Peterborough district

many roads were impassable from fallen trees, and in Milton Park several hundred were uprooted. Around Sherwood Forest and on the fine estates adjoining considerable damage was done.

## OBITUARY.

**Mr. Thomas Worth.**—After a brief illness Mr. Thomas Worth, for many years past in the employment of the Liverpool Horticultural Co., and latterly of John Cowan and Co., of the Vineyard Nurseries, Garston, near Liverpool, died on Saturday, the 23rd inst., from influenza at the age of 31 years. Mr. Worth was a man of considerable promise. He was for some years in the employment of the late Mr. Enoch Harvey, and eventually became his Orchid grower. After some years he became Orchid grower to the Company, and for the past two years acted as traveller for Messrs. John Cowan and Co.

**Alexander Goodman More, M.A.**—We regret to record the death of the above well-known naturalist, which took place on March 22 at his residence, Leinster Road, Dublin. Mr. More was a native of Malvern, but had long resided in Dublin, he having formerly held the post of senior assistant, and eventually curator of the Dublin Natural History Museum, from which post he retired through ill-health some few years ago. His principal work is the "Cybele Hibernica," written in co-partnership with the late Dr. David Moore and published in 1866; and they also wrote a very interesting report on "The Climate, Flora, and Crops of Ireland," published (p. 165) in the report of the International R. H. S. Exhibition of 1866. Mr. More was one of the best living authorities on the British and Irish flora, and we believe had a new edition of the "Cybele" in hand at the time of his death. He was 64 years of age.

**Mr. William Dean.**—Lovers of the Pansy will learn with regret the death of Mr. William Dean at his residence, Sparkhill, Birmingham, on Saturday, the 23rd inst., somewhat suddenly, at the age of 70 years. Born at Southampton on July 8, 1825, his father being at the time foreman of the Hill nursery of Mr. W. Bridgewater Page, as soon as he left school he was taken into the office. In 1843 he went to Belfast as foreman to Messrs. Scott Bros., nurserymen, but after a short sojourn in the north he came to London and entered the nurseries of Messrs. E. G. Henderson and Son, St. John's Wood. About 1850 he started business at St. John's Wood, but after a few years the business was abandoned, and in 1853 he went to Slough under Mr. Charles Turner. Leaving there in 1857, he established a nursery at Shipley, near Bradford, York-shire, and about 1876 he came to London and took charge of the London branch of the Lawson Seed Company. When this was abandoned he went to Birmingham as manager of the Chad Valley nurseries of Mr. R. H. Vertigans, from thence to the Solihull nurseries of Mr. Thomas Hewitt, and later as manager to Messrs. A. Blizard and Co., Edge Lane Nursery, Solihull. From thence he removed to Dolphin Road, Sparkhill, Birmingham, and started as a florist, making a specialty of Pansies and Violas, where he died. He was the first to grow the Belgian or fancy Pansy in this country at Shipley. In 1862 Mr. Dean sent out new varieties of his own raising, and continued to do so for several years. While at Shipley he assisted in the editing of the three last volumes of "Gossip of the Garden," and when that work was discontinued at the end of 1863, he edited the "Florist's Guide" during its brief existence. Mr. Dean was one of the jurors at the International Horticultural Exhibition in 1866, of whom few still survive. He was assistant secretary to the Midland Counties Carnation Society, and in August last organised the successful Viola conference at Birmingham.

**The weather in West Herts.**—There has not been a single cold day for more than a fort-

night, and during the same period only two cold nights. On the 22nd the temperature in shade rose to 63°, which is the highest reading recorded here as yet during the present spring. At both 1 foot and 2 feet deep the temperature of the ground now stands at 44°. At the latter depth the temperature has never been higher this year, but at 1 foot deep it has fallen 4° since the 22nd. There has been lately a good record of bright sunshine, the average duration for the last five days amounting to 5½ hours a day. On the 24th the wind proved very boisterous, many of the gusts reaching the force of a whole gale. At 30 feet above the ground the mean velocity for the five hours ending 5 p.m. was 38 miles an hour, and the highest record for any hour 44 miles, between 2 and 3 p.m.—direction west. This is the highest velocity for any single hour that has been recorded here during the ten years over which my observations extend. In order to give some idea of the violence of some of the individual gusts, I may state that for a quarter of a minute the mean rate amounted to 60 miles an hour. *Scilla sibirica* came first into blossom in my garden on the 25th, which is six days later than its average date of first flowering in the previous eight years, and forty-five days later than last year.—E. M., *Berkhamsted*.

**Presentation to Mr. Wilson.**—A presentation was recently made by the Earl and Countess of Lindsey to Mr. Wilson, steward and head gardener at Uffington House, who is leaving after twenty-six years of service. The gift was a handsome watch and chain, which, when opened, showed the following inscription: "Presented to E. Wilson by the Earl and Countess of Lindsey as a token of sincere regard. March, 1895." Added to this was an elegant brass tripod lamp, also a gold scarf pin from the Ladies Bertie.

**Presentation to Mr. W. G. Head.**—A few months ago some friends of Mr. W. G. Head, judges and exhibitors at the Crystal Palace, formed themselves into a committee to raise a private fund with a view of making a presentation to Mr. Head in recognition of his work at the Crystal Palace. The presentation, which took the form of a purse of money, was made on the evening of Friday, the 22nd, at the Restaurant, Victoria Station. In the absence of Mr. William Marshall through illness the chair was taken by Mr. Richard Dean, the treasurer of the fund, who briefly sketched Mr. Head's career, commencing with his start at Arundel in 1853 under Mr. Geo. McEwen; thence to Shrubland Park, Ipswich, in 1856; from there to Drumlanrig in 1857, under Mr. McIntosh, where he remained four years. He then became gardener at Castle Dykes, Dumfries, but owing to ill-health returned to the south of England in 1863, and took a foreman's place at Abernant, South Wales, and later was foreman at Arundel under Mr. J. Wilson. In 1867 he was in the Chiswick Gardens of the Royal Horticultural Society, and from there went to Kew. In 1872 he went out to Calcutta and formed a new garden and nursery for the Agricultural Society of India, remaining there six years. He returned home in 1878, and soon after succeeded Mr. George Thomson in charge of the gardens and grounds at the Crystal Palace. The chairman eulogised Mr. Head's work at the Crystal Palace and his management of the various exhibitions, and concluded by handing Mr. Head the purse of money, with the hearty good wishes of all the subscribers.

**Fisher, Son and Sibray, Limited.**—This company was registered on the 21st inst., with a capital of £50,000, to take over the old-established business of nurserymen, seedsmen, and florists, carried on by the partners in Messrs. Fisher, Son, and Sibray, at Handsworth Nurseries, near Sheffield, Fitzalan Square, Sheffield, Church Street, Rotherham, and elsewhere.

**Names of plants.**—S. N. T.—1, *Eupatorium Wendlandi*; 2, *Alonsoa incisifolia*; 3, *Scalaeuella Kraussiana*; 4, *Franciscea calycina*; 5, *Franciscea macrantha*. E. Curtis. *Candelia cuneata*.—J. P. C.—Tree by *Altema arborea* (sens.)

# BURMESE LILIES.

## GRAND IMPORTATION JUST RECEIVED IN SPLENDID CONDITION,

COMPRISING

**L. Wallichianum superbum (sulphureum), I. nepalense. L. Lowi** (very rare), **L. Bakeri** (new, white flowers), &c, &c.

As these Lilies are found growing together, no attempt has been made to keep them separate, but from the collector's descriptions we have no doubt that all the above varieties will be found amongst them, and possibly others, especially from the smaller sizes.

Fine Bulbs, 8s. doz.; grand Bulbs (7 to 8 in.), 15s. doz.; very large Bulbs (9 to 10 in.), 2s. 6d. each, 24s. doz.

SPECIAL OFFER WITH FULL PARTICULARS JUST OUT.

## R. WALLACE & CO., COLCHESTER.

EXTRAORDINARY BARGAIN. Catalogue of Cuttings, Plants, and Bulbs. To Amateurs and Others.

### SHOW ZONAL PELARGONIUMS.

Rev. Bartram, Lord Salisbury, Comet, Cannell's Favourite, Parker's Favourite, Mrs. Barker, Rosy Morn, King of the Purples, Lady Tommyson, Maid of Wales, Mrs. French, Lauree, Mrs. Wildsmith, Abigail, Gloire Lyonnaise, Dr. Rotheru. One well-rooted cutting of the above sixteen varieties for 10s.; half, 5s., free by post. Cash with order.

CUCUMBER, TOMATO, and MELON plants for Sale, price on application. Seeds and plants of every description.

A. W. WARREN, Gloucester Nursery, Hampton, Middlesex.

### ROSES. ROSES.

THE BEST AND CHEAPEST IN THE WORLD. 12 acres of Roses. 100,000 grand plants to select from 50 choice Perpetuals for 21s. Purchaser's selection from 400 best varieties. Catalogue free. 21 choice standards or half standards for 21s. Purchaser's selection. The following are my selection, carriage free, cash with order: 50 choice dwarf Teas and Noisettes, 12s. 6d.; 12 choice Climbing, 7s.; 12 Hybrid Perpetuals, dwarfs, 7s.; 12 beautiful Teas and Noisettes, 9s.; 6 lovely yellow Roses, 5s.; 6 Maréchal Niel, 5s.; 6 Gloire de Dijon, 4s. 6d.; 6 choice Moss Roses, 4s.; 6 old Cabbage Roses, 4s.; 6 old-fashioned Roses, 4s.; 6 crimson Monthly Roses, 3s. 6d.; 6 pink Monthly Roses, 2s. 6d.; 6 white Monthly Roses, 3s. 6d.; 6 quick-growing Climbing Roses, 2s. 6d.; 12 Sweet Briars, 3s. My selection, cash with order. Thousands of Testimonials. Catalogues free.

JAMES WALTERS, Rose Grower, Exeter.

### V. Lemoine & Son's Catalogues of Novelties

Including Begonia elegantissima alba and other bedding and tuberous Begonias, Richardia Elliottiana, Crasula albiflora new sets of Abutilons, Fuchsias, Single and Double Zonal Pelargoniums, Pentstemons, Flaxo decussata, Gladioli, Mont breias, Double Clematis, Double Lilacs, and other plants, are Now Ready, and will be sent free to all applicants. Gladioli Lemoinei and Gladioli Nauceianus (First Prizes at the Paris and Chicago Universal Expositions) are not subject to disease under the climate of England. "I have never heard that they are attacked by the dread disease, or dwindle away in the mysterious manner, which is a characteristic of the gandavensis family."—T. C., THE GARDEN, Nov. 18, 1893.

For descriptions and prices apply to

V. LEMOINE & SON, NANCY, FRANCE.

2s. 6d. per doz. **LOOK! LOOK!!** 2s. 6d. per doz.

100,000 Plants must be cleared, viz., Achillea mongolica, Aconitum Napellus, Agrostemma atrosanguinea, Caltha palustris fl. pl., Campanula grandis alba, Chelone barbata, Chrysanthemum maximum, Doronicum Harpur-Crewe, Funkia Sieboldi, Helenium pumilum, Helianthus strumosus, Hemeocallis flava, Iris germanica, Pyrethrum in var., Rudbeckia Newmanni, Spiraea filipendula fl. pl., Stenactis speciosa major, Trollius europaeus, 2s. 6d. per doz.; 24 for 1s.; 100 for 15s. Lists free.

LOGAN & CO., Chad Valley, Birmingham

LOVELL'S YORKSHIRE STRAWBERRIES.—Autumn transplanted, 2s. 1s.; 100, 3s.; 500, 12s. 6d., carriage paid. Descriptive List free.—W. Lovell and Son, Strawberry Growers, Birtfield.

Catalogue of Cuttings, Plants, and Bulbs.

JOHN RICHARDS & CO.

(Late John Morse & Son)

Our Catalogue of the above will be forwarded free to any address. It contains all the new and choice varieties, Dahlias, Chrysanthemums, Verbenas, Fuchsias, Pelargoniums, Phlox, Geraniums (Zonal, Tricolor, Bronze, Silver and Ivy), Petunias, Heliotropes, Calceolarias, Tropaeolums, Pansies, Pentstemons, Bourdianas, Lantanas, Finks, Veronicas, and all kinds of bedding plants, Achimenes, Begonias (double and single), and Gloxinias; Bulbs.

The Nurseries, Fursley, Gloucestershire.

### CARNATIONS.

The best new and old varieties now ready for planting out in all the classes. 31 First-class Certificates in 1894 awarded to J. Douglas for Carnations. 1st prize Auriculas, show and alpine to name. Carnation and Picotee seed, saved from best named varieties, hand fertilised, 2s. to 3s. 6d. per packet. Auricula seed, only the best, 1s. 6d. to 2s. 6d. per packet. Fancy Primrose and Polyanthus, 1s. to 2s. 6d. per packet. Calceolaria seed (Douglas's best strain), 1s. 6d. to 2s. 6d. per packet. Silver Medal R.B.S., 1894. Cioraria (Douglas strain), 1s. to 2s. 6d. per packet, from 1st prize named varieties in 1893-4. R.B.S. Catalogue gratis and post free on application.—JAS. DOUGLAS, Great Bookham, Surrey.

### STUARTIA PENTAGYNA, fine specimens,

4ft. to 5ft. high, 7s. 6d. to 10s. 6d. each; Stuartia virginica, nice plants, 3s. 6d. to 5s. each; Acer polymorphum atrosanguineum, from seed, all raised from dark-leaved kinds, varying in colour, but all good, stout-branched plants, 9in. to 12in., 12in. to 15in., 15in. to 18in., 9s., 12s., 18s. per doz.—T. SMITH, Daisy Hill Nursery, Newry.

### CHINA ROSES.—Old semi-double scarlet,

fine plants, 4s. doz.; Cranioisi, deepest crimson, 6s. doz.; Old Blush, 4s. doz.; Climbing Cranioisi, very fine, 12s. doz.; Laurette Messing, coppery rose, 9s. doz.; Rival de Poestum, semi-double white, lovely, 8s. doz.; Souvenir de Lord Brougham, finest of all, 12s. doz.; Louis Philippe, bright and good, 4s. doz.; and many other sorts.—T. SMITH, Daisy Hill Nursery, Newry.

### LARGE Peach Trees to fill houses at once:

no delay.—R. GILBERT begs to intimate that he can supply the cream of varieties in standards, half-standards and dwarfs, warranted true to name and in vigorous health. Upwards of 800 ft. of walling devoted to their culture.—For particulars apply to R. GILBERT, High Park Gardens, Stamford.

### STRAWBERRY PLANTS a Speciality.—

If any of your readers require an abundant crop of Strawberries next year, let them write to R. GILBERT, Burghley, Stamford, and leave the selection in his hands for early, mid-season, and late varieties, and success is a certainty.

### CHRYSANTHEMUMS, early or outdoor

flowering indispensable for cut flowers in bloom from June until November; finest collection in the Kingdom (via press opinion); cuttings now ready; catalogues post free. C. SHAW, Florist, Sherwood, Nottingham.

### LAXTON'S SEEDS.—The new Catalogue,

enlarged, contains a very complete list of all good novelties and specialities of merit from every source, as well as a sound general list of standard sorts good and reliable; prices are reasonable; lists free.—LAXTON BROS., Seed Growers, Bedford

### MESSRS. BELL'S LIST.

New and Enlarged Edition (1072 pp.), with numerous Illustrations, demy 8vo, cloth, 9s., net.

JOHNSON'S GARDENER'S DICTIONARY. A New Edition, thoroughly Revised and considerably Enlarged. By C. H. WRIGHT, F.R.M.S., and D. DEWAR.

"We are glad to see the publishers of this valuable work again in the field with a new edition, thoroughly revised and considerably enlarged. It is without doubt one of the most reliable and important gardening dictionaries that has ever been published; in fact, as a dictionary and guide for gardeners, amateur or professional, its equal is not to be found in horticultural literature... forms a marvellous digest of matters horticultural, and a standard work for the guidance of all interested in the art and science of Gardening. It is beautifully printed, and the style in which it is turned out is highly creditable to the eminent publishers."—The Horticultural Times.

Fcap 8vo, flexible binding for the pocket, 7th Edition, Revised, with New Appendix, 4s. 6d.

THE BOTANIST'S POCKET-BOOK. By W. R. HAYWARD, containing, arranged in a tabulated form, the chief characteristics of British Plants

This volume is intended as a handy Pocket Companion for the Botanist in the field, and will enable him to identify on the spot the plants he may meet with in his researches.

BELL'S AGRICULTURAL SERIES. CROWN 8VO, EACH 2s. 6d.

PRACTICAL FRUIT CULTURE. A Treatise on Planting, Growing, Storage, &c., of Hardy Fruits for Market and Private Growers. By J. CHEAL, F.R.H.S.

"One of the very best agricultural manuals we have seen."—Field.

TILLAGE AND IMPLEMENTS. By WALTER J. MALDEN.

"A most practical little volume... Every farmer should read it, because it is just the sort of work to interest and instruct him."—Farmer and Stockbreeder.

SOILS AND THEIR PROPERTIES. By Dr. W. FREAM, B.Sc. Lond., F.L.S., F.G.S., F.S.S. With a Geological Map of Great Britain.

THE FARM AND THE DAIRY. By Prof. J. P. SHELDON.

"The best cheap English book upon dairying that we have ever seen."—Livestock Journal.

MANURES AND THEIR USES. By Dr. A. B. GRIFFITHS, F.R.S.E., F.C.S., late Principal of the School of Science, Lincoln.

"This little book may well take its place in an agricultural library as supplying knowledge which otherwise might need research through many scattered sources of information."—Nature.

THE DISEASES OF CROPS AND THEIR REMEDIES. By Dr. A. B. GRIFFITHS.

"Beyond praise for its clear and concise description of the plague old-fashioned countrymen regarded as a visitation only prayer and fasting could remove."—National Observer.

LONDON: GEORGE BELL & SONS, York Street, Covent Garden.

## FERNS A SPECIALITY.

We have an immense stock of all kinds of Ferns, Stove, Greenhouse, Filmy, Hardy Exotic, and British, including many very beautiful varieties rarely seen, but which ought to be more generally grown. Catalogue free on application.

W. & J. BIRKENHEAD, F.R.H.S. FERN NURSERIES, SALE, near MANCHESTER.

## Our Hardy Grown Roses.

DWARF, TEA and H.P.

UNINJURED BY FROST.

CATALOGUES ON APPLICATION.

COCKER & SONS, Aberdeen.

### BOOKS ON ROSES by Wm. Paul, F.L.S.

"The Rose Garden," ninth edition, royal 4to, 20 coloured plates and numerous wood engravings, 17s. 6d.; the same, imperial 8vo, without coloured plates, 8s. 9d. "Roses in Pots," seventh edition, illustrated, 2s. post free. "Roses and Rose Culture," seventh edition, illustrated, 1s. post free. "The best works on Roses are those by Mr. William Paul."—Journal of Horticulture.—WM. PAUL & SON, Waltham Cross, Herts.

### ROSES IN POTS.—A magnificent stock of

extra strong plants established in 8-inch pots, suitable for present forcing or greenhouse culture. Tea-scented and Noisette varieties (dwarf and climbing kinds), 20s. to 60s. per dozen; Hybrid Perpetuals, 24s. to 42s. per dozen.—WM. PAUL & SON, Waltham Cross, Herts.

### PLANTING SEASON.—Immense stocks of

Hardy Evergreen and Deciduous Trees and Shrubs of all kinds; all well transplanted and in excellent condition for removal. Rhododendrons off loan a speciality. Priced descriptive catalogue free by post.—WM. PAUL & SON, Waltham Cross, Herts.

### CHOICE CUT FLOWERS.—CHAS. E.

COOPER, Wholesale Florist, 33, Russell Street, Covent Garden, and 370, Flower Market, is open to receive consignments of choice cut flowers, foliage, &c., for sale on commission or buy for cash. For further particulars apply as above. Bankers: The National Bank, Charing Cross Branch. Telegrams: "Lapageria, London."

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ORCHIDS.

## THUNIAS.

THIS genus comprises several beautiful species, all of which are plants that enjoy a strong heat and plenty of moisture to grow them to perfection. Where these accommodations are at command, Thunias should be grown, for they are of exquisite beauty and make a bright display, the drooping racemes of bloom ranging in colour from white to bright purple. These plants enjoy a very pronounced period of rest after the flowering season, and thrive best when repotted annually. This should be done when the new growths begin to appear from the base of the old pseudo-bulbs, which generally occurs about the beginning or middle of March; therefore if repotting has not yet been done, I would advise it to be seen to at once. Good drainage is very necessary and the pots require to be about half filled with clean, broken pots, the remainder filled with a good porous compost of rough peat, fibrous loam and chopped Sphagnum Moss, with a good proportion of silver sand. Thunias are plants that may be easily propagated and root very freely; therefore nice specimens should be made up each spring. This may be done by placing several stems into a pot, according to the size, and which should be about 3 inches apart, firmly fixed by tying each bulb to a small stick. Water must be very sparingly applied until they become fairly established and the new growths well above the surface, when a liberal supply should be given throughout the summer and not be diminished until the foliage commences to change colour, when it should be gradually lessened until the plants are finally at rest. In the summer months whilst in strong, active growth an occasional application of weak liquid manure will be found very beneficial. When in the dormant state they should be placed in a light and dry place and water entirely withheld, and as soon as they are started at this season they must be placed near the glass in the East India house, for as much light as is available is necessary to ensure good results.

Thunias are natives of India, where they grow upon trees, and are widely distributed over the Himalayan Mountains, Moulmein and Lower Burma, usually at an altitude of from 1500 feet to 3000 feet. They are closely allied to Phajus, but even very distinct from that genus in having no pseudo-bulbs, and the blooms are produced upon drooping racemes about the months of June and July. The kinds below mentioned are all worthy of cultivation.

**T. ALBA**, a very useful kind, has been known for a number of years. It was introduced into this country about sixty years ago by Messrs. Loddiges, of Hackney. The sepals and petals are pure white, also the lip, the latter being beautifully veined with purple and yellow.

**T. BENSONI** is the most richly coloured in the family, having flowers some 3 inches to 4 inches in diameter, and of a beautiful bright magenta-purple colour. It is very free-flowering, and was discovered by Col. Benson some thirty years later than the preceding kind. It first flowered in the Royal Gardens, Kew.

**T. MARSHALLIANA**, a very pretty species, somewhat resembles *T. alba*. It has white sepals and petals, and the lip is white at the front, the

other portions pale yellow, veined with bright orange. It is, however, distinct, and a native of Moulmein. A form with a light yellow lip was named by the late Professor Reichenbach *P. Marshalliana ionophlebia*, but it is very scarce. These all grow about 3 feet in height, the last named being somewhat taller and more robust in habit, and all are well furnished with light green leaves. A grand addition to this group which must not be forgotten is the beautiful hybrid raised by Mr. Seden in Messrs. Veitch's nursery and also in the gardens of the late Mr. Tall, of Manchester, at the same time. This is named

**T. VEITCHIANA**, and was obtained by crossing *T. Marshalliana* with *T. Bensoni*. It produces fine flowers with white sepals and petals, flushed with deep rosy purple at the tips, the front lobe of the lip being bright purplish rose with fringed lines of orange on the disc, the side lobes white.

WM. HUGH GOWER.

**Platyclinis glumaces**, or, as it is more familiarly known in our gardens, *Dendrobium glumaceum*, is one of the most elegant little Orchids that produces its flowers during the early months of the year. I have recently noticed this doing remarkably well in several collections in the neighbourhood of London. It always appears to form a well shaped plant and flowers very freely; the long filiform pendulous raceme of white blooms has a graceful appearance and a very pleasing fragrance.—H. G.

**Cypripedium Druryi**.—This is one of the most distinct species we have, but, unfortunately, appears to be getting a scarce plant. The flowers are produced singly upon erect scapes, and measure about 3 inches in diameter. These are of clear yellow throughout, the lip having a more golden shade than the other segments, the black broad central band on the sepals and petals being very characteristic. This kind, unlike the majority of members in this family, does not vary in either size or colour. It is a native of the Travancore Mountains, India, and is at present well represented in The Firs collection at Sydenham. The blooms being so thick in texture keep in full beauty longer than those of other kinds of *Lady's Slippers*.—W.

**Cymbidium eburneum**.—This lovely species is one of the finest in the genus, and a few years ago was an exceedingly rare plant. At the present time, however, it is to be found in most collections, and always attracts admiration when in bloom. A flower of this comes from J. Pocock, but it is small in size. No doubt it will improve another season when the plant becomes better established. I recently noticed a fine form flowering in Mr. Dorman's collection at Laurie Park, Sydenham. It is about seventeen years ago since it was first flowered in this country, and is a native of the Khasya Hills.—W.

**Cypripedium Chamberlainianum (J. C. W.)**.—This pretty and distinct species was introduced quite recently by Mr. Sander, of St. Albans. It produces many flowers upon an upright stem, and is quite different in formation to any other kind yet in cultivation. It appears to be a continuous bloomer, for I have seen it at different places nearly the whole year round. The petals have a peculiar twist, one being curled one way and the other the reverse, a peculiar character not to be found in any other known kind. The principal merit of this species is its lovely bright rose-coloured pouch, which will no doubt be the means of producing more vivid colours in the lip of future hybrids. It is certainly worthy all your attention.—W. H.

**Dendrobium nobile and its varieties**.—At this season of the year when this useful species is in flower it is remarkable to see its extensive variations. *D. nobile* and *Odontoglossum crispum* are two Orchids grown in larger quantities than any others, especially for cut blooms, for which they are most admirably adapted. I have received several blooms of *D. nobile Cooksonianum*, but the best form I have seen this season is flower-

ing at Cambridge Lodge, Camberwell. The flowers there have the large maroon blotch on the petals, extending a long way down and of exceedingly bright colour. Another beautiful form of this comes from James Ingle for a name. This is a fixed sport from the typical plant, for it has appeared in several collections and occasionally turns up amongst importations of *D. nobile*. No doubt the deepest coloured form of this species is *D. nobile nobilium*, which is of rich amethyst-purple, slightly paler at the base of the segments and with a white zone surrounding the very deep-coloured blotch on the lip. The individual flowers are also larger than those of the type. There are many plants called by this name which are nothing but good coloured ordinary forms, the true variety being still very scarce. A nice plant is at present flowering in The Firs collection, Laurie Park, Sydenham, where this family of Orchids is made a speciality.—G.

**Cattleya Trianae**.—Flowers of this very useful spring-flowering *Cattleya* come from various correspondents. They vary considerably in colour and markings, the majority being very beautiful, but as there are already some most distinct named varieties, I do not think it advisable for every plant to receive a varietal name. This would only lead to a great deal of confusion. At the present time we have such an enormous quantity of this species in cultivation, that what one considers as a unique form may generally be found in several other collections. The flower from "J. C. W." marked "alba" has a decided tint of rose in the sepals and petals, and therefore cannot be called a pure white variety.—W. H. G.

## HARDY CYPRIPEIDIUMS.

THE essential details in the culture of hardy *Cypripediums* are moisture, shade, and a soil mainly composed of peat and leaf soil. Where it is intended to grow them in the open ground—and nowhere do they flourish so well and continue healthy so long—it is best that some special preparation be made for them. In the first place a suitable position must be chosen, and one sheltered from the north and east winds possessing the needful shade overhead will do well. The next step will be to excavate the soil 18 inches deep, or if the soil be light and well drained 12 inches deep will be sufficient. In the case of clayey soils, a few inches of rough crocks or clinkers will be necessary to form a drain, which is not needed with light soils which drain freely. The hole may now be filled in, using roughly chopped peat and half-decayed leaf soil in about equal parts, with the addition of some rough charcoal nuts and Sphagnum Moss if obtainable. In this mixture the plants invariably do well provided a sufficient supply of moisture is forthcoming in the growing season. This latter may be easily arranged by either utilising the overflow from a fountain or by conducting water to the bed in pipes. Surrounding the bed with a perforated pipe where the supply could be regulated would be a simple as also an efficient way of ensuring the requisite moisture, which in the growing season should be at semi-saturation point. In planting it is important that the roots be spread out horizontally and not thrust into a small and deep hole, for if treated thus they will assuredly rot. A very cursory glance at the tufts of *Cypripedium spectabile* will give some idea of the mode of rooting in this species, and this will constitute a good guide. Frequently many roots perish either during transit or by exposure prior to being packed, and are best cut away as close to the crown as possible. When placing the plants in position, let the hole be as wide as the extent of the roots; indeed this is the better way when planting large beds, carefully firming the soil and covering the crowns 2 inches deep.

*C. SPECTABILE* is at once the best and most vigorous species from an all-round standpoint, the sepals and petals white, with rose-coloured much-inflated pouch. In this species the colour varies somewhat, always, however, more or less rose tinted.

*C. PUBESCENS* has sepals and petals of yellowish brown with yellow lip. Very similar in respect of colour is the smaller-flowered and fragrant

*C. PARVIFLORUM*, of equal hardiness and simple requirements.

*C. CALCEOLUS* has sepals of a brownish hue and pale yellow labellum. This species is sometimes found growing in leamy soil, though it does not appear essential, as it grows quite well in the above-mentioned material and with less abundant supplies of moisture.

These are the more vigorous growers of this group, attaining a height of from 12 inches to 20 inches, and being usually procurable in good-sized plants, produce a good effect when grouped together in the open ground. The remaining species, by reason of their rarity and small size, are perhaps safer grown in pans in a cold frame till well established. These include the dwarf growing *acaule*, the lovely *guttatum* and *macranthum*, *occidentale*, and the rare *C. arietinum*, seldom seen in cultivation. *C. californicum* is a newer kind, growing when established 2 feet high and producing axillary blossoms, therefore one of the most distinct. E. J.

#### NOTES FROM THE ISLE OF WIGHT.

IN your impression of the 23rd ult. Mr. Miles writes, "Following Mr. Smith's advice, I will only say that here, with a zero frost, *Carpenteria californica* seems quite safe." I am sorry to say that Mr. Smith's advice on this head quite escaped me, and I have not seen it at all, so that I should feel much obliged to Mr. Miles if he would tell us more clearly what the measures were which he took and which served him so well. This is a point on which I feel a great deal of interest just now, and I should welcome enlightenment from any quarter from which it may come. A very fine specimen indeed of *Carpenteria californica* which has been in my garden for years has been terribly mauled by the frost. I think it is alive and will break out again in due time, but that is all I can say for it, and I shall be glad to have my anxiety allayed on this head. It was wrapped round and round with folds of an old herring net which I bought for the purpose, and which has answered well enough till this terrible season, but I cannot say that I am satisfied with it under existing circumstances. Nevertheless, in most years the idea has proved to be a good one. I am indebted for it to Miss Jekyll. The net, of course, has allowed free ventilation and has generally given sufficient covering. The late Sir Wm. Hutt was excessively fond of flowering shrubs, and he had a fine collection of them at Appley Towers. He was, for the most part, against any covering at all, and denied its usefulness. I have often had a conversation with him about this matter. Now what is the state of the case with those very shrubs? I have not had time to go over and look at them, but his nephew expects great losses will soon be apparent, and speaks very dolefully about it. Altogether, I think it is a rather difficult thing to know how to act for the best. If we could forecast the future at the beginning of the winter, the whole matter would be easy enough. The question now really is, what is the best average solution of a very great difficulty? I should have done a great deal more for my own shrubs than I esteemed to be necessary for them if I could have anticipated that we were going to have 23° of frost in the Isle of Wight. Such a thing was never dreamt of before by the oldest inhabitant. But while wrack and ruin are the burden of our song, it is always curious to notice some strange exceptions to it. I sent a blossom of *Narcissus monophyllus* to Mr. Barr last week which was taken from the open

ground, and which was, perhaps, the very last bulb in my garden which I could have supposed would perform in that way. *Poinciana Gillesii*, which is treated to a pot and kept in the temperate house at Kew, did not seem to mind the cold in the slightest degree, and is now in a very good condition. It had no covering at all and is completely uninjured. These things are strange, and we may have stranger still.

HENRY EWBANK.

P.S.—I should, perhaps, say that *Narcissus monophyllus* had a bit of glass over its head affixed to one of Mr. Wood's holders, but even then its survival and blossoming in that way are curious.

#### LIFTING LARGE TREES AND SHRUBS.

THE assistant secretary read the notes on "Lifting Large Trees and Shrubs" sent by Mr. Crasp, who was to have lectured on March 26. Mr. Crasp stated that many trees were too much crowded at planting, this often being done for shelter. The remedy usually adopted was to cut away growth, but much could be done by lifting to other sites and thus give space. New pleasure grounds and parks were often bare of trees, and to improve this, lifting large trees gave the owner a valuable effect at once, and he stated that large trees, no matter how old or large, could in the hands of experienced men be transplanted without injury and removed a long distance, thus avoiding cutting away. On many estates great improvements could be made by removal of large trees and the landscape improved. He ventured to state that the work of lifting was not such a costly matter as many supposed, and there was no question as to the work being a success. Conifers were specially suitable for lifting; also large Cedars; these could be lifted when from 20 feet to 50 feet in height. He mentioned the only species he had failures with was *Abies Pinsapo*. There was no difficulty in lifting trees twenty to one hundred years old, and he advised the work to be done in early autumn, September being the best season. There is greater chance, too, of new roots being formed at the time named, as the sap had practically done its work. The size of ball, even for large trees, need not be great, but the soil must be firm. If the ball be about 8 feet in diameter that is sufficient, and if at all loose the soil must be securely bound up with matting or a wooden frame to prevent injury to the roots. Dry soil would require much moisture, and before getting under the roots a trench 5 feet wide and 4 feet deep should be made. Mr. Crasp then referred at length to the system he adopted, the mechanical appliances necessary, the need of ample water at the roots, and spraying the tops of trees after removal.

The chairman (Mr. Cheal) gave some interesting remarks on the subject, naming various instances of old trees being lifted successfully.

#### AMARYLLIDS AT CHELSEA.

EVERY year at this season the house in Messrs. Veitch's Chelsea Nursery given up to the *Amaryllis* is a feast of colour, the many hundreds of spikes creating a display of one flower in its many forms that could not be seen in any other country. The exhibition, for such it may be appropriately described, shows not the slightest falling off from the splendid displays of previous years, and there is this important feature, too, that this year's plants are all seedlings, none, or at least very few old varieties being represented. The gradual weeding out of everything that does not attain a certain standard of perfection has resulted in every flower now to be seen in this nursery being almost faultless in form and colour. Mr. Heal has worked steadily and successfully towards eliminating the green in the flower and its starry form, and in the near future green will not be a colour to disfigure the *Amaryllis*, for such it does, as it is objectionable in association with many of

the shades of crimson and allied colours. Several of the finest novelties are selfs, one splendidly defined colour, and it is these rich self colours that are such a picture at Chelsea.

But the hybridist has gained many points. One gets now a strength in the plant unknown in the earlier days of the *Amaryllis*, bulbs bearing two sturdy spikes crowned with bold flowers delightful either for colour or symmetry, and there are many more light-toned varieties. We have often expressed the opinion that a pure white *Amaryllis* is in the near future, and certainly the varieties at Chelsea now in bloom point strongly to the accomplishment of this ideal, and such a flower will be of extreme beauty, welcome in many forms of decoration with suitable foliage plants for contrast. The display at Chelsea is an object lesson in showing what the hybridist may accomplish in moulding, so to say, a flower into a certain form and adding to the variety of colouring. An *Amaryllis* of not many years ago would look poor indeed against the splendid varieties that now grace the plant house, stately spikes bearing blooms of great breadth and charming colouring. The segments of some of the flowers we measured were nearly 5 inches across, and yet one could not accuse the raiser of getting coarseness into the blooms. The *Amaryllis* named Dr. Masters is an example of beautiful proportion in the flower, but this kind does not now stand alone in this respect, as an inspection of this year's exhibition will show. Many others are finer than this, the flowers conspicuous for symmetry and colour.

It seems that perfection has been already reached in this flower, but that is what we wrote some time ago, and yet as each April comes round one discovers an advance either in form or colour. This year the light-coloured varieties make a decided break amongst the forest of spikes of crimson and orange-scarlet kinds, and in every greenhouse or conservatory worthy of the name a good group of *Amaryllids* should be placed, the spikes being relieved with foliage plants of not too tall stature.

It seems unnecessary when the list of varieties grows to such a length each year to mention varieties, but the following must be recorded. Amongst the light-coloured kinds all of the following show a distinct advance: *Cupid* is very pretty, white, with a veining of scarlet, *Norma* being distinguished by crimson lines; whilst in a kind named *Brandon* we get an unusually fine flower, with very broad, robust segments, only the upper portion with the veining of crimson. *Idea* is almost colourless and a dainty flower which we can scarcely have too much of, and the same may be said of *Ilam*, another exquisite flower for purity. *Armoire* is very large, but not coarse, with a feathering of scarlet on the segments; *Panacea*, *Hilda*, *Caudonald* (very fine flower), *Crinia*, *Maer* (very charming), *Marmorata* and *Otley* being all splendid acquisitions to this section.

Amongst the dark-coloured *Amaryllids* many kinds of great beauty could be found, none more so, however, than one named *Macar*, the flower of superb form, not large, and of a rich quite self crimson, with a satiny lustre on the segments as if shot with a pellucid velvety suffusion of a more intense tone than the actual body colour. *Patna* is a bold flower, crimson-scarlet; *Anatino*, bright scarlet; and *Gorgeous*, of very large size, but without coarseness, the flower deep self crimson. We may also mention *Hadsor*, crimson; *Guthrie*, bold and brilliant orange-scarlet; *Carridon*, very large, the colour bright orange-scarlet; *Finedon*, one of the boldest flowers in the collection and crimson-red in colour; *Asta*, pure crimson-scarlet, a beautiful flower for symmetry and tone; *Roydon*, a glorious *Amaryllis* with broad segments, brilliant orange-scarlet in colour, and *Lucan*, of a similar shade. The flowers of the dark-coloured section present a bewildering variety of shade, so that it is difficult to describe them, but it is this colour variety that we cannot have too much of, especially when there is happily no tendency to get muddy purples, magentas, and other objectionable flowers, such as disfigure not a few other classes of plants

## STOVE AND GREENHOUSE.

## MARGUERITE CARNATIONS.

THESE CARNATIONS have now been in cultivation some few years, but they are not at the present time gaining in favour. For this there must be some cause, not necessarily the same in each particular instance, but none the less so. Being raised as a rule from seed rather than from cuttings, there is a predisposition to make a luxuriant growth, not altogether robust perhaps, but of rapid development and consequently sappy. This should be guarded against by not using too rich a compost from the very commencement. Under pot culture it will be better to employ chiefly loam and sand with a little leaf-soil if the former be at all of a heavy character. It will be better also to err on the side of small pots rather than the opposite extreme. Some of the best flowers I have seen were from plants in

a strong one in this strain. This no doubt arises from their parentage, this Carnation in all probability being related to *Dianthus chinensis* or the Indian Pink. Where it is not convenient or practicable to grow a stock of the other Carnations in pots, there the Marguerite Carnation will be the most useful. As in the case of all seedlings, there will be a percentage of singles which should at once be destroyed.

PLANTSMAN.

*Spiræa compacta multiflora*.—Despite the fact that the herbaceous plant so generally grown for forcing under the name of *Spiræa japonica* is not a *Spiræa* at all, yet it is so universally known as such that the general public will not recognise any name other than that it has so long borne. That at the heading of this note is a variety of the common kind, in which the inflorescence is borne in a denser and more compact manner than in the older form, but whether superior to it is doubtful. I prefer the lighter and more tapering spikes of the common kind, while others look upon the

as an admirable setting to them. It is of very easy culture, and all that is needed for forcing is to lift the clumps from the open ground and put them into pots in a cold frame, from whence as the spring advances they may be taken into the greenhouse, where a little group of good flowering examples is very bright and cheerful as well as uncommon.—H. P.

## CARNATION NOTES.

I AM much obliged to Mr. Douglas (p. 163) for answering my inquiry respecting the variety Duke of York. The great drawback with so many of the Tree Carnations is their unwillingness to flower freely in the dead of winter. December, January, and February are the three months in which these flowers are most useful to me. For this reason I have discarded several good varieties which do not open their flowers until March, house room being somewhat limited. Good winter-blooming yellow Carnations seem scarcest of any.

Pride of Penhurst is often quoted as belonging to this section, but with me it never did much till spring, and did not seem to care for any but the coolest treatment. I used to grow Andalusia, a very pale yellow fringed variety, but have now discarded it, as it is a poor grower and a shy flowerer—at least, that is my experience of it. Mr. Douglas mentions Mlle. Carle as being one of the freest whites. This I have grown for some years, but as quantity for cutting is my chief need I shall grow less of it in future, the new variety La Neige far exceeding it both in freeness of growth and free flowering. For every bloom of Mlle. Carle I get three or four of La Neige, each plant being simply laden with blooms and buds, which do not burst and are beautifully scented. I feel certain that when La Neige becomes more widely known it will be largely grown both for private and sale purposes. In regard to Miss Joliffe Improved, I am of the same opinion as Mr. Douglas, viz., that there is no difference between it and the original variety. I do not now label my plants of Miss Joliffe, and cannot distinguish the one from the other. To grow Tree Carnations well they ought not to be mixed with other subjects, but have a house or part of one to themselves. Many batches of what would otherwise be useful plants are ruined by too much heat in winter. I never care for a higher figure at night in the Carnation house than 45° in mild weather, and when by reason of frost more pipe-heat is needed, 40° will keep the plants safe. Slight fortnightly fumigations to prevent attacks from green-fly are best, as if once this pest gets into the points of the young shoots it is often most difficult to eradicate.

J. CRAWFORD.

## FLOWER GARDEN PESTS.

PERHAPS the smallest in size of our garden pests, but by no means the least in respect of the damage it does to plants, is the red spider. Its name is not very appropriate, as it is not a spider, but a mite. As, however, it spins a kind of loosely-made web on the undersides of the leaves, it is not to be surprised that it has received the popular name of red spider, particularly as its scientific one—*Tetranychus telarius*—does not convey much meaning to the ordinary gardener. This little creature is a most tiresome and destructive pest wherever it makes its presence felt. It is very indiscriminate in its choice of the plants it feeds upon and attacks those grown under glass as well as those grown in the open air. When this pest is present in large

Marguerite Carnations in a jar. Engraved for THE GARDEN from a photograph sent by Miss Barrowes, Moreton House, Buckingham.

quite small pots. Firm potting will also tend to better results, whilst no artificial feeding should be allowed until the plants are well advanced in the flowering stage. Another mode of culture is that of planting the seedlings out, but the same lines as regards soil and its firmness must be observed. If planted out the growth will be greater, whilst a more bushy habit will result. So far there is an advantage, but sufficient time must be allowed for fresh root action when lifted before cold weather again sets in, otherwise the results will not be good. In any case plenty of light is absolutely necessary to aid in maturing the growth. The seed should have been sown early in March, but it is not yet too late to do so. Do not, however, endeavour to make up for lost time by raising and growing the young plants in too much warmth. By the time the seedlings are pricked off a cold pit or house will afford sufficient protection for them. Although there is in some instances a perceptible fragrance, this much appreciated merit of the Carnation is not

newer form as the best. For many years there has been a golden veined variety of *S. japonica* in which the inflorescence is an exact counterpart of the newer *compacta multiflora*, so that this would seem to have originated from the variegated form. This last, I see, received a first-class certificate from the R.H.S. as long ago as 1869. The variety *compacta multiflora* has certainly been largely grown within the last two or three years.—H. P.

*Begonia manicata*.—"H. P." (p. 205) does well to call attention to this winter and spring flowering *Begonia*. Not only does it succeed under the conditions mentioned, but it grows freely and blossoms abundantly in an ordinary greenhouse. For this reason it is more valuable to many than it would be if always requiring a warm temperature.—E. M.

The spring Bitter Vetch for forcing.—This, which was illustrated on page 186, though thoroughly hardy, is very useful for flowering under glass for the embellishment of the greenhouse during the spring months, for the peculiarly coloured flowers are borne in great profusion, and the bright green freshly expanded leaves serve

numbers the leaves on which it feeds soon turn a sickly yellow colour and look as if they had been scorched, for the sap of the leaves is drawn off by myriads of these little mites, which congregate on the undersides of the leaves, where they spin a very delicate web, in which they live and multiply very rapidly. This web and the excrement of the red spider soon choke up the pores of the leaves. The latter deprived of their proper amount of sap and unable to obtain the carbon from the atmosphere which they need are soon in a sorry plight. Melons, Cucumbers, Vines, Hops, Kidney Beans, Roses, Strawberry plants, Orchids, Cacti, Ferns, Laurustinus, Lime and fruit trees are the special favourites of these pests. Red spider has a great dislike to moisture, and it is in dry seasons that plants suffer most from it. If, however, plants are not allowed to get too dry at the roots they will not suffer nearly so much as if they are. These little creatures breed with great rapidity, and it is well to take any plants which are attacked by them in hand at once. The red spider lays its eggs among the threads of its web; they are round, white, and, of course, very minute, when we remember that the full grown parent is hardly more than the sixtieth of an inch in length. They are hatched in about a week, and the young at once begin to feed. It may be a matter of surprise how such minute creatures can pierce the comparatively tough skins of leaves, but it must be remembered that they usually feed on the undersides of the leaves, which have more delicate skins than the upper ones, and that their mouths are furnished with a pair of mandibles, between which is a pointed sucker or beak. As I have already mentioned, their greatest enemy is dampness, either in the atmosphere or in the leaves. Situated as they are on the under sides of the leaves, which, owing to their drawing off their juices, curl more or less, they are not much affected by rain, and for this reason when wishing to destroy them by means of syringing, care should be taken to direct the insecticide against the under sides of the leaves. A great deal may be done in keeping the attacks of this pest in check by syringing with plain cold water, but if the attack be a bad one, one of the following mixtures should be used. Sulphur is one of the most efficient agents for killing it, but in its ordinary form it will not mix well with water, but should be treated according to the following manner: Boil together in 4 gallons of water 1 lb. of flowers of sulphur and 2 lbs. of fresh lime, add  $1\frac{1}{2}$  lbs. of soft soap, and before using, 3 gallons more of water, or mix 4 ozs. of sulphate of lime with 2 ozs. of soft soap, and when well mixed add 1 gallon of hot water. Tobacco water and soft soap is also a good insecticide for this pest. The red spider usually passes the winter under some shelter, often choosing stones, rubbish, &c., near the plants it infests, so that all such things should be carefully removed. It cannot be insisted on too often or too strongly that leaving rubbish, stones or anything about in gardens under or in which insects can shelter themselves is the most foolish thing to do, as under such circumstances it is impossible to keep a garden free from many kinds of pests. Gooseberry bushes which are attacked are often much benefited, particularly in warm, dry seasons, by a good mulching, but this mulching must not be allowed to remain under the bushes during the winter, as it may form a harbour for the red spider.

Roses may probably, with little fear of contradiction, be considered the favourite flower in gardens, and as such is perhaps cultivated more

than any other flower. The Rose is, however, unfortunately attacked by a great number of insects. In my last article I dealt with the aphides, which are their most hurtful enemies. The various kinds of Rose maggots also do an immense amount of mischief at times. These maggots destroy the foliage, which they not only utilise for food, but by curling the leaves up or by fastening two or three together, form a secure dwelling place in which they are safe from the attacks of many enemies. These caterpillars are remarkably active, as everyone knows who has attempted to catch them. Snugly ensconced in the shelter which they have prepared, when you open the leaf which contains them they wriggle out and drop before you have fairly caught sight of them. Some choose the Rose buds, which they destroy and entirely prevent from coming to perfection by eating holes into them. These insects are the caterpillars of several kinds of small moths which belong to the family Tortricidae. The moths are small, brownish or greyish insects, measuring from half an inch to 1 inch across the wings when fully extended. There are quite seven or eight species which feed on the leaves and shoots of Roses. There is not much to be done in the way of applying insecticides for getting rid of these insects, as from the way in which they shelter themselves it is very difficult to make any insecticide reach them; and from what I have just said, it is by no means easy to catch them alive. Pinching the rolled leaves or those that are spun together is the easiest way of disposing of these caterpillars if you can make sure that the caterpillar does not drop out during the operation, but perhaps the most certain plan is to hold a basket under the leaves or buds, so that when they are cut off they will fall into the basket, and the caterpillar will be caught if it tries to escape. The basket must be one out of which they cannot drop. The leaves and shoots cut off should be burnt or laid on a hard path and a roller passed over them. When the bushes are pruned in the spring the shoots which are cut off should be burnt, as there are often eggs laid upon them.

Besides the caterpillars of these moths there are some much larger ones which feed on the leaves of Roses, gnawing great notches at first in the edges of the leaves and eventually reducing them to mere skeletons. They do not attempt in any way to conceal themselves, but owing to their colour they are not easily recognised until you happen to notice one, when the others (for there are generally a considerable number on the same bush) will at once be seen. These caterpillars are the grubs of the Rose saw-fly (*Hylotoma rosarum*). When full grown they are about three-quarters of an inch in length. Their heads are yellow, their bodies are yellowish on the back, greenish at the sides and white below; both backs and sides are sprinkled with small shining black tubercles, which bear a few fine hairs. Soon after they are full grown they descend to the ground, and, burying themselves, each becomes a chrysalis within a cocoon. The insects of the first brood remain in this condition nearly two months. From those of the second brood the perfect insect does not emerge until the following spring. The most effective way of getting rid of this insect is to pick them off the bushes by hand, but syringing with the extract from 3 or 4 lbs. of quassia chips added to 2 lbs. of soft soap and mixed with 50 gallons of water, as recommended for green-fly, or the recipe of tobacco water and soft soap would no doubt be useful.

Another species (*Eriocampa rosea*), which is not a very troublesome pest, feeds on the upper

surface of the leaves much in the same way that the Pear slugworm does. And yet another species (*Blenocampa pusilla*) rolls up the leaves until each leaflet forms a little tube in which it lives. This species is by no means an abundant one, and I have never known an instance in which it was the cause of any real injury to the plants. The grubs are quite small and several live in the same leaf. Gathering the infested leaves and burning them would be the simplest and most effective remedy.

G. S. S.

#### FROST IN THE FLORIDA ORANGE GROVES.

WHILE we are deploring the effect of the long frost, a story of devastation comes from semi-tropical Florida before which our disasters, grievous as they are to us, sink into comparative insignificance, for it is a story of ruin, widespread and absolute. I had heard a report that the Orange groves had been badly damaged by frost, but had received no particulars until a friend's letter reached me the other morning. He has now been in Florida for nearly twenty years, and his groves have occasionally suffered during the "cold snaps," but the possibility of such a visitation as that of the past winter had never been contemplated even by the most pessimistic.

He wrote that everything had promised an exceptionally favourable season, that when the frost came things were looking better than he had ever known them. The Orange groves had extended year by year. Each year the quantity of vegetables grown for the New York market had been well-nigh doubled, and with each recurring winter a larger concourse of visitors flocked to the southern peninsula in search of sun and the warm sea breezes of the Gulf of Mexico. Then, in the early morning of December 29, after a noonday temperature in the shade of 77° on the preceding day, the thermometer fell to 14°, a drop of over 60°. Needless to say that thousands of acres of early vegetables were killed, as were the young plantations of Oranges, which were estimated to cover in the State of Florida an area of nearly 100,000 acres, while the bearing groves, on which a heavy crop of Oranges was approaching perfection, were denuded both of fruit and leaves. Florida's planters, being for the most part natives of our islands, did not fold their hands, but set to work in earnest to repair such damage as was reparable. The young trees were killed; time would show whether the old trees would recover or perish. In neither of these cases could anything be done, but there was still time to retrieve the loss of the vegetables, and these were therefore planted in larger quantities than before. During five weeks of rains and genial warmth these crops flourished amazingly and gave promise of a bountiful return, when once more, after a hot day, the wind in the night flew round to the north-west and the thermometer again fell to 14°.

On the subject of this second frost I quote from a letter which I have seen that bears out in almost every detail the experiences of my friend. "Contrary to expectations, the bearing groves threw out a splendid new growth, and in a month's time had put out their flowering spurs, showing in the majority of cases an immense bloom. On Thursday, February 7, at noon the thermometer stood at 70°; on Friday morning at 6 o'clock it stood at 14°. The trees were just coming round from a knock-down blow, and, without the protection of their leaves, suffered proportionately more. Grove land worth 1000 dollars an acre last week is not worth 1 dollar an acre to-day." Both the writer of this letter and my correspondent agree in saying that the effects of these disastrous frosts will mean depopulation of the State and ruin to many of the present dwellers in it. Planters who have resided in the State for a number of years and who have done well will be able to tide over the lean time coming, and, if they wish, to extend their holdings at a merely nominal cost; but for such

as have but lately started in the business of fruit and vegetable growing, and who have little or no capital to fall back upon, the prospect is black indeed. S. W. F.

## KITCHEN GARDEN.

### SUMMER LETTUCES.

To get a good salad in the summer months it is necessary to grow those varieties which stand hot weather, and for that purpose Cabbage Lettuces are best. They are also preferred by many for eating, the leaves being more tender and readily blanched. The Cos varieties are much grown by market growers for sale during the summer months, and those who supply the markets may question my assertion as to Cabbage varieties being best for summer use. My note, however, refers more to home culture. Salad during the hottest part of the year is most appreciated, and to get a good salad the best blanched Lettuces are required. Those who study quality in salads prefer kinds which give a large quantity of blanched leaves, crisp and sweet. A great deal depends upon the selection of varieties for summer use, and I find it best to grow two or three kinds. Those that will do best in hot dry seasons are most suitable for summer crops, but for spring I have a wider selection. Frequent sowings are necessary on different aspects, and above all in rich or well-manured soil to prevent plants failing or a scarcity at any time.

Lettuce during the summer often fails, drought and heat being the principal causes. In a moist, rich soil there are fewer failures, and with summer crops it should be borne in mind they are sooner over. Frequent sowings should be made in small quantities, selecting various positions of the garden according to the season. Many failures occur by thick sowing, others by transplanting, both to be avoided by sowing often and giving the plants room to develop. To get a regular supply of good Lettuce I advise sowings to be made fortnightly up to the middle of July, and if sown in good well-enriched land there will be abundant supplies at all times and of good quality. For early summer cropping I reserve a richly manured border under a wall facing east, and for July supplies a north border. For later crops at the end of July and through August it is a good plan to sow a single row between the Celery trenches. The plants delight in the well-worked soil and are of splendid quality for late summer use, as at that season there is less fear of collapse. I have seen north plantations fail, but much depends upon culture. If the soil is well manured and dug, with due attention to thinning and moisture, there is no fear of failure; but it is essential to have plenty of good solid manure not more than 6 inches under the surface to provide a rich root run.

As regards summer varieties, some kinds are less suitable than others, but in dry, sandy soils few varieties equal the one here illustrated.

The Drumhead Lettuce is a large type and certainly one of the best summer Lettuces grown. It is known under many other names, such as the Malta Lettuce. The Neapolitan is a form of it, and there is the Standwell and New York, doubtless selections of the Drumhead, and all good for summer use, being of sweet, crisp flavour and well adapted for soils in which others do not succeed. The Drumhead is a large grower, with the centre leaves well formed over the heart of the plants. When cut up for salad it is beautifully blanched and of a sweet taste, which many of the loose green Cabbage varieties lack. It is much grown in hot climates, hence its name, the Malta and Neapolitan. The Standwell referred to is closely allied to the Drumhead and has the same merits, being a long time before running to seed. There are two varieties, green and brown. I prefer the latter, it being more like the Drumhead in flavour. Other good kinds are Favourite and New York, the first somewhat like Drumhead in appearance, size and quality, the outside leaves being more curled. New York is a newer introduction, remarkable for its size, excellent quality, and the length of time it

*Drumhead Lettuce. From a photograph sent by Mr. Jas. Sharp, Finchden Cottage, Teeterden.*

stands without running to seed. It is solid, crisp, and of splendid flavour; indeed, if I were restricted to two summer varieties I should give New York and Drumhead the preference.

G. WYTHES.

**French Bean Newington Wonder.**—Although this Bean is seldom met with, it is one of the best for early work in pots or boxes. Indeed, there is, I think, very little to choose as regards cropping, earliness and quality between Newington Wonder and the well-known Osborn's Forcing. It is naturally dwarf, and does not run up spindly in dull dark weather like some sorts that are commonly forced early in the season. When first sent out it was grown extensively by the London market growers, a sure proof of its merits. According to my experience the best Beans for forcing are Newington Wonder, Osborn's, Syon House and Ne Plus Ultra. The last is perhaps more suitable for sowing from January onwards than earlier. Syon House is now ignored by many, but I have always found it serviceable.—J. C.

**Early Cauliflowers.**—I quite agree with Mr. Wythes that there is a decided gain in the time of cutting early Cauliflowers by sowing in the autumn. We hear a great deal about losses from the opponents of the system through the severe

winter and other causes, but this is entirely imaginary and not borne out by facts. I have got this season as good plants of Early Dwarf Erfurt and Walcheren for early planting as ever I had. The mistake is generally made in sowing too early, the first week in September being quite early enough. At no time must the plants be coddled. On the approach of the past severe weather the sides of the frame were banked up with litter and effectually protected on the top with litter and mats. Our plants never had daylight for a month. By uncovering gradually when the weather breaks the plants do not take the least harm. For summer use I rely on The Pearl and Walcheren. These are far less likely to button than Early London, which I note lately a correspondent recommended for summer use.—A. YOUNG.

**A profitable Kale.**—Of all green crops nothing seems to have stood the intense frost of the early part of the year so well as Asparagus Kale. A great proportion of the Scotch Kale has succumbed, but the Asparagus Kale to my surprise is safe almost to a plant. Offsets are now springing freely from the stems in all directions, and will furnish many tender dishes in a short time. If seed is sown in May, the plants put out on good firm land, and allowed plenty of room, they will grow strong and stocky, proving very useful late in the spring, when most of the other varieties are past. Indeed, if a good breadth is planted, plenty of tender delicious greens may be had till the earliest Cabbages come in. I do not think Asparagus Kale is known or grown so much as it deserves. J. CRAWFORD, *Coddington Hall, Newark.*

**Dwarf winter greens.**—Severe as has been the winter, it is pleasing to find that the dwarf winter greens have come through the trying ordeal the best. Asparagus Kale, Dwarf Green Curled Kale, and the dwarf plants of Cottager's Kale will do good service. Brussels Sprouts have been hard hit. On walking over our quarters after the snow had gone, I noticed that a few plants which had been bent over under the weight of snow, and so become quite covered, were quite fresh. Wood pigeons have done as much damage as the frost to our winter greens. Lately one or two correspondents have called attention to that excellent Cabbage Winnigstadt. I grow it as a winter Cabbage, sowing early in May.—A. YOUNG.

**Aids to early vegetable culture.**—I can quite bear out the remarks of Mr. Douglas (p. 184) as to the value of ground vineries, as they are termed, for forwarding such early vegetable crops as he mentions. For small gardens, where hotbeds and frames are an impossibility, there is nothing better for this purpose, and in larger gardens they are also valuable. The late Mr. D. Lumsden had great faith in protectors for forwarding early crops. He used long and narrow portable lights, each from 10 inches to 1 foot in width and 6 feet long. The sides were formed of two thin boards each about a foot in depth, and fixed together by cross-pieces. The tops inside were grooved. In these grooves were run sheets of glass. These were used for fixing over rows of early Lettuce, young Cauliflowers, French Beans, &c. The winter of 1879 was just as disastrous as this as regards green vegetables, and I remember these protectors were found of great value.—A. YOUNG.

**Small early Cauliflowers.**—Many now rely upon the small-heading dwarf varieties sown in January or the first week in February instead of sowing the somewhat larger sorts in autumn. Where this was done the seedlings will need attention as soon as the rough leaves are developed. If a frame elevated on a warm bed of leaves can be afforded, it will answer better than anything, the soil used being somewhat retentive. Where boxes are used, a few rough leaves will act as drainage, and thus the rooting depth be increased. As each handful of plants is removed from the seed pans, dust the roots and stems with flowers of sulphur; this will check the disease known as blacklegs. Plants in frames must be kept somewhat close for a week,

and then gradually aired until complete exposure is practicable. Those in the boxes should be placed in a warm greenhouse for a fortnight, and at the commencement of April placed in frames to be hardened off. Where a spare pit is at hand some may be pricked out into it, so that when large enough to remove to open quarters a percentage may be allowed to remain to produce some extra early heads.—J.

**Celery running to seed.**—At page 184 Mr. Douglas, in his notes on early vegetables, speaks of this running to seed when sown in boxes and raised in heat. For several years I have raised my early Celery in this way. I have only experienced this difficulty once in fifteen years, this being when the plants were allowed to remain in heat too long, and then pricked out into boxes, placing these in frames heated with manure. I sowed early enough, so that when the plants are well up they are removed into a cold house, and when strong enough pricked out into a cold frame till fit for removing into the trenches.—JOHN CROOK.

#### SCARCITY OF VEGETABLES.

IN the course of my rounds among amateurs and cottagers in Somersetshire I find a marked scarcity of vegetables other than Potatoes. Some few are able to vary the monotony with Carrots, Onions, and Parsnips, but far more are badly supplied with the two former, and owing to the frosts could not get at the latter. Turnips most of them grew, but had left them on the ground, only to be completely destroyed by frosts. Farmers had also apparently determined in their own mind that this was to have been a mild winter, and as a consequence large breadths of Swedish Turnips were left on the ground to be fed off at leisure. Of these the frosts have made a mess, and already the smell of decay is observable.

In the gardens all is desolation, scarcely a particle of green to be seen. Most of the Brussels Sprouts present the appearance of having been scorched to death; Borecole is only a few removes better, and Broccoli is completely destroyed. Old Cabbage stumps are all dead; young Cabbage plants if not killed are yet badly scorched, and if winter Spinach recovers from the effects of the frosts I shall be agreeably surprised. Leeks are very much damaged in places, but in some instances they have withstood the severe weather remarkably well. Celery, whether roughly protected or not, is as good as finished, the ridges being hard frozen through. When I have to speak of these occurrences, and which happen five nights in a week, the question is invariably asked, How could these difficulties have been obviated? It is a question not so difficult to answer as may at first sight appear. My contention is that we ought always to prepare for a severe winter. It may frequently happen that nothing approaching a very destructive frost happens when we are best prepared for it, but sooner or later we are caught napping, and then we wish we had made it a rule to always prepare for the worst. In the first place we ought to re-arrange our ideas as to what should be grown for winter and early spring use. Some of the most popular vegetables are really the least reliable, while others that deserve to stand higher in the estimation of the middle and working classes are not much grown, and that, too, in spite of their being thoroughly reliable. In the former class I would place Broccoli and Savoy. Every owner of a garden must have a few or many rows of Broccoli, but how often do they survive a sharp frost, or if they do survive, how many of them are eaten? More often than not whole beds of them are fit to cut at much about the same time. The variety that I

always advise those who have plenty of rough pits or fruit houses to grow most extensively is Veitch's Autumn Protecting, all the later plants being housed or stored in pits before severe frosts spoil them. It may be thought rank heresy to speak against Savoy Cabbage, but I hold them to be of less value than they are usually considered. Too often the bulk are unfit for use or are overgrown and bursting long before there is any real demand for them, and it is very rare that either Dwarf Green Curled and Drumhead are other than coarse, only the early Tom Thumb section and Dwarf Elm proving tender and mild in flavour. A severe frost ruins all that may be left at midwinter. Brussels Sprouts will stand a moderately severe frost as well as most vegetables, but when frosts are accompanied by biting easterly winds it seems to dry them up. Half-grown Borecole is all killed. Very strong stems well dotted with side shoots have survived in many places, and will yet do good service. If the Arctic Kales sent out by Sutton and Sons stand the strain on them this season as well as I have known them do severe frosts and cold winds in other winters, they ought to be grown everywhere. They are in two colours—purple and green—and belong to the same section as the ordinary Scotch or Green Curled. There are also two colours in the Asparagus Kale; both cook green. This, again, is a most reliable kind, and in some gardens I have been in are all there are alive. Presently they will push up fine succulent greens most freely, and the more they are gathered from the more they will spread and grow, the season extending to June. Those farmers who annually sow or plant large breadths of Thousand-headed Kale on the chance of their doing good service other than as cattle feed will have good cause, I should say, to congratulate themselves upon their perseverance. If within easy distance of a large town, and London in particular, they will be able to sell breadths of good produce at from £75 to £100 per acre. This has happened before and will again occasionally. Unfortunately we only eat Thousand-headed Kale when we cannot get anything else, and as a consequence very little of it is grown. What we want is something equally hardy and productive, but of superior quality when cooked. The Cottager's Kale is a step in the right direction, and since these notes were started I have come across a breadth in which at least one half the plants have stood the test remarkably well. With a return of milder weather these survivors will produce an abundance of greens that will be fully appreciated. This is not the first time by any means that Cottager's Kale has proved reliable, and those who have a fairly large household to supply ought always to grow a breadth of it. There may come a time when it would be acceptable in the dining-room occasionally as well as in the servants' hall, where it most often goes. Sprouting Broccoli, again, is not often seen in the dining-rooms of the wealthier classes, but it is by no means to be despised. Not infrequently it stands much better than the ordinary Broccoli, but I have seen none alive in my rounds. It is most unfortunate that so few comparatively appreciate the Leek. It is, as I have already pointed out, one of the most reliable winter vegetables we have, and I believe I am right in describing it as a delicately flavoured as well as very wholesome vegetable. Medicinal properties are also ascribed to it, and which are to a certain extent deserved.

Those who were sufficiently careful with some of the kinds of vegetables that can be stored or kept for winter use have long since realised what a boon these have proved or are proving.

Foremost among these I would place Runner Beans. Instead of letting these hang on the plants to spoil, they ought to be gathered as fast as fit for use, prepared for cooking, and then placed in large jars, each layer of sliced Beans being covered with a layer of salt. Stored in a cool, dry place, they keep admirably, and if well soaked in water twelve hours prior to cooking will taste nearly or quite as good as fresh gathered Beans. There is a great waste in that direction especially in years when Beans are exceptionally productive till very late in the season. Green Peas should also be stored rather than be allowed to spoil. Cottagers in many districts keep nearly all the Vegetable Marrows they grow for winter use, hanging them up in their kitchens. As a rule, though, they throw them away after they think they have kept them long enough. This time they are using them, and these stored Marrows are not bad eating. Farmers are a more short-sighted race than cottagers even. Many of them have tried the blanched tops of Swedish Turnips when these have been gathered from roots stored in heaps, and found them nearly equal to good Seakale, yet they never think of placing a quantity of roots in a cellar with a view to have early and numerous dishes of blanched shoots. This season very few of them have saved any of their roots, so that Swedish Turnips, commonly called "Swedes," cannot be bought to use as a vegetable, or for placing in cellars or other dark places to give blanched growths in quantity. We ought always to grow Seakale extensively. Even those who have few or no facilities for forcing, too, could yet forward Seakale in cellars, or even blanch the tops by heavily moulding over the crowns. Unblanched growths would be acceptable enough this season. Of other garden vegetables that ought to be more grown for winter use to form a dish occasionally or often, and not merely for flavouring soups, I would place Jerusalem Artichokes in the front. They are easily grown, quite hardy, or may be stored, and properly served would soon become popular where at present despised or not known. Chinese Artichokes again are very productive, easily kept, and good to eat. Onions ought to be largely served as a vegetable, and Carrots, Parsnips, and Turnips properly cooked are wholesome and good. All these with Salsafy and Scorzera for those who know what to do with them could always be stored in quantity, and when other vegetables are scarce would prove most acceptable. W. I.

**Sowing Broccoli too early.**—This is a matter of considerable importance, and one giving rise to comment each season as the time of sowing comes round. Quite recently I note that Mr. Crawford advises early sowing of such sorts as Baekhouse's, Snow's and Cooling's because they require a long season of growth. Possibly this may be quite true in Mr. Crawford's case, but in the southern and western counties such early sowing is unnecessary, particularly so in the case of Snow's Winter White. I used to sow this with others late in March and in April, but never had a useful crop until the sowing was deferred till May. I am cutting useful heads from plants lifted just previous to the first spell of sharp weather and laid in in a border in a house from which frost was excluded, and with such a dearth of green vegetables these are extremely valuable. Let outdoors they would have quickly succumbed, and the variety is one that always requires similar treatment, and the chances of obtaining matured heads is extremely doubtful, due as it is in early or midwinter. It is not usually convenient to have vacant ground at the time that Broccoli sown early would need to be either temporarily or permanently planted; and left crowded in the seed bed to await convenience

at once deprives them of the chance of making a stout starchy growth. Those who have been in the habit of sowing their Broccoli in March should this year make a point of making an additional one in April, and of Snow's variety in May, and the results will no doubt favour a repetition of the practice in future seasons—at least in the warmer counties. As I have not practised in the north I cannot say what the effects of late sowing in Broccoli might be, but perhaps some of your correspondents would favour us with their experience on that point. More than ordinary precaution against bird and insect pests need be taken when seeds are sown thus late, because the loss of these cannot well be made good by further sowing, unless it be under glass, and this is not advisable only in extreme cases.—W. S., *Wills*.

**Summer Cauliflowers.**—There will be such a very great and general scarcity of late Broccoli this summer through the late severe winter killing large breadths outright, that the value of the earliest summer Cauliflowers will be almost untold, and there will be a desire and, indeed, a necessity on the part of all vegetable growers to forward this crop so as to have it at the earliest possible date. It is not many years since the Early London was a standard sort and grown by almost everyone for early work, but of late so many varieties have been introduced that are both earlier and better, that its usefulness is becoming less appreciated year by year. Perhaps one of the best known of the select early Cauliflowers is Veitoh's Dwarf Foreing, as this has been in cultivation for some years, and if I was confined to one sort only for summer work this would claim first place. I grew this last year alongside Early London, and its superiority was not only found in its turning in more quickly, but in remaining fit for use so much longer than did the old one. It takes up less space, too, which in an extra early kind is of much value. Hand-lights, boxes and pots will all have to be requisitioned for hastening on the growth, coupled with shelter from threatening frost and cold winds, and those who have chosen one or more of the best early selections may, if the weather should soon become genial, make good to some extent the loss of the Broccoli crop. From pots they sooner become established than when planted out from boxes, unless they are allowed abundant space, so that the soil and roots can be lifted out in good sized squares. The plants should in any case receive no check.—W. S., *Road Ashton*.

**Globe Artichokes.**—The past winter has been a trying one for these plants, especially in low, wet districts where the soil is heavy and retentive. I have always found it a good plan in such situations to cover the ground about the roots with about a foot of fresh leaves in the autumn before frost sets in. At the first approach of severe weather the roots are covered with Braeken or other litter, which secures them against the most intense frost, and this is not removed till the weather is favourable in March. Where such covering has been applied it should now be removed, and the ground between the plants forked over to admit the light and sun to warm the soil. Young suckers will soon make their appearance, and when these are about 6 inches or 8 inches high the soil should be removed from round the plants in order that they may be taken off with a heel. To grow good Artichokes the ground must be well tilled: therefore the plot on which it is intended to plant the suckers should be previously trenched and liberally manured. I plant in rows 4 feet apart, allowing a distance of 3 feet between the plants. Three suckers are used to form a clump, and these are planted in a triangular manner 6 inches apart; in this manner more crowns are produced the first season. Though Artichokes may occupy the same ground for several years, I prefer to allow them to remain only two, for by planting a portion each season larger heads can be had in addition to a much longer supply; for whereas the old roots will produce an early crop, those planted in April, if due care be taken to water them till established, will continue to throw up flower-stalks

till quite late in the autumn. Last season I was able to cut some good heads as late as the middle of December. The plants are gross feeders, and on light land will need plenty of support while growing in the shape of liquid manure.—H. C. P.

**Turnips.**—If a little care is taken in preparing the site, a sowing of Turnips may now be made even in unfavourable gardens. Although the roots prefer a cool, moist bottom in mid-summer, yet at this date a south or west border is best, also a fairly light, warm soil. Some time ago I advised the preparation for this sowing by turning up and incorporating with the soil burnt refuse, sweepings of drives, and some rough leaf-mould, and in preference to spit manure the use of guano or fowls' manure. If, however, the ground has now to be prepared, the latter had better be withheld, or damage may be apprehended. Early Milan and White Dutch may be sown in equal quantities in shallow drills 1 foot apart, well firming the surface afterwards, and covering with fish netting to protect from birds. If when the seedlings show themselves any trace of Turnip fly appears, dust at once with wood ashes; indeed, an occasional sprinkling as a preventive is best. Where the hint was taken last month and Early Milan sown in a frame on a slight hotbed, growth will now be rapid. If any more thinning is needed let it be done without delay, as Turnips left too closely together very soon become leggy and fall about in all directions. If loose, press the seedlings into the soil gently with the finger and thumb. Keep moist by tepid waterings, administered on fine days. As soon as the bulbs are fairly formed give a good watering either with diluted farmyard water or guano water. Fly must also be watched for assiduously, as even in frames it will sometimes attack the crop. This sowing will afford capital Turnips very early, the flavour being good by reason of growth never being checked, as are sometimes early outdoor lots.—J.

**Late Queen Broccoli.**—The arctic weather that we have experienced this year has caused such a scarcity of vegetables in the kitchen garden as many of us never remember before: even curled Kale is killed, and all Broccoli, with the exception of one variety, viz., Late Queen, is destroyed. The sort named has withstood the great frost with comparatively little damage; the edges of the leaves are browned a little, but the centres are uninjured, and fully 90 per cent. will produce heads at the proper season. In another garden not far away there has been a greater loss amongst Late Queen, only about 50 per cent. remaining safe. In that case the grower did not sow until the end of April, as he does not believe in sowing earlier. Mine were sown by the middle of March, and I think that is the reason why the plants have stood so well, as the position is not sheltered and not so favourable in that respect as that of the grower referred to. No doubt the early sowing gives the plants a longer season of growth, which is better matured, and thus able to pass through greater cold safely than plants raised later. I have sown Late Queen in February when the soil was in excellent condition with satisfactory results, these never turning in before the usual time. It is possible that we may have an equally severe winter again, and I would suggest sowing the above variety now or immediately the soil is ready and transplanting, not less than 20 inches apart each way, as soon as the plants are large enough into fairly rich and firm soil.—W. G., *Ross, Hereford*.

**Sowing Peas and Beans.**—When should I sow Duke of Albany Pea and Mammoth Long-pod Broad Bean to come in on July 25?—F. P. K.  
\*.\* This question would be less difficult to answer if one could foretell the weather, which is the important factor. Another point deserving of attention is that Duke of Albany Pea is much sooner over than some kinds. It crops freely, but only lasts a short season. Most of the crop can be cleared in a fortnight, there being no succession of pods, as in Ne Plus Ultra. My advice to secure Peas for the date named is to sow twice, say the second week in April and again ten days

or a fortnight later. In this way if the weather is favourable those from the first sowing will be past their best, but the pods from the second sowing will be in perfection, and you will have two strings to your bow. So much depends upon position, soil, and culture, that precise dates cannot be given. Most growers, however, at that season allow twelve weeks with quick-podding varieties. If the soil is dry more time is required at the start, and for Peas to be at their best at the time named, there should be ample food at the roots with plenty of moisture. Two sowings of the Mammoth Long-pod Bean should be made. The plants are not over so quickly as those of Duke of Albany Pea, but the Beans soon get black, and if required for exhibition must be young, but fully grown. I would advise sowing this crop on a north border or on a cool site. Growth is rapid, and in dry soils the plants are soon infested with black fly, which checks growth. By making two sowings there is less chance of failure. The first should be made about the same time as advised for Peas generally, and should the season be favourable the second lot will be best. One lot may be sown on a warmer border, and there will be no fear of failure, as should the weather be hot the lot sown in April will provide the supply. In a warm garden the crop would come to maturity in about ten weeks from the time of sowing.—GROWER.

**Pea Dsisy.**—This sterling variety merits all that is said in its favour by Mr. Wythes (p. 185). I have sown it both in frames and outside, and for the former purpose it is a grand acquisition, as it forces admirably, and bears its large pods of deliciously-flavoured Peas in profusion. The fact of its originating from a cross between Stratagem and Culverwell's Giant Marrow, the produce re-crossed again with Stratagem, and also receiving the award of merit from the Royal Horticultural Society on at least two occasions, at once stamps it as one of the best Peas ever introduced.—W. G. C.

**A good winter Turnip.**—Many growers sow a quarter rather late to provide Turnip greens, and in mild winters rely upon small roots for spring supplies. The severe weather will have upset many calculations as regards the spring supply of green vegetables, and but few Turnips will be left to provide roots or green tops. With me all the Turnips have perished except the Chirk Castle Black Stone, the roots of which at this date (the middle of March) are sound and the tops quite green, the new growth pushing up freely. I have always prized this variety for winter use, but shall do so more now, as the tops next month will be invaluable. I think the hard black skin this variety possesses must protect it largely, as the bulbs are quite sound. I earthed up the rows late, as I find this a great protection. Some may object to the colour of the root of Chirk Castle Turnip, but when boiled the flesh is white and the quality excellent.—S. H. B.

**Notes on runner Beans.**—This vegetable is almost indispensable in most gardens, as it is not only delicious and highly productive, but serves admirably as a screen to hide any unsightly objects, or to prevent certain quarters of the garden being too much in view. For a number of years I have thus employed runner Beans—in fact, all the Beans that I require for the use of the family are so grown; and I believe each year the produce improves from sowing annually in the same places that are liberally manured for each crop. If the Beans are not too crowded and neatly staked, I question if anything else will act so well as a screen, or give such an ornamental appearance. There is now a great variety of Scarlet Runners of excellent merit, and for light, hot sandy soils I have found none to surpass Ne Plus Ultra. If immense pods are desired, Carter's Elephant or Carter's Jubilee Runners will meet the wishes of anyone, as both freely produce pods of great length, very straight, deep green in colour, and remarkably tender. The Czar is another very large sort that I have grown ever since its introduction, but this year it

will be superseded. If possible room should be found for the new climbing French Bean, as it is a fine acquisition. Treated in the same manner as Scarlet Runners, it will bear enormous crops of pods, and will continue cropping for a long season. Provided no pods are allowed to become old and form seed, daily supplies of tender Beans can be picked until frost cuts the plants down. Those gardeners who have to provide French Beans in quantity early and late in the season will find this variety a great boon.—W. G. C.

**Tomato Duke of York.**—I was glad to see Mr. G. Wythes' brief note on this new Tomato, and, with him, believe it will get popular. Last year I had a few plants sent me by a friend for trial, and they produced a very heavy crop of handsome fruit. So satisfactory was the variety for home consumption and also for market, that I am growing it much more extensively this year, and it will replace both Perfection and Ham Green. I may add that all my Tomatoes are planted in soil that has been thrown into heaps at the roadside by the roadmen when cleaning up the roads. In addition to decayed vegetable matter, this road soil contains some lime from the limestone used in metalling the roads, and Tomatoes seem to thoroughly enjoy this compost, as they make very short-jointed wood, with a profusion of fruit of a fine flavour. After the soil has been watered several times it becomes very firm, and this may account for the sturdy and prolific character of the plants. In the discussion on Mr. Collette's paper on "Diseases of Tomatoes" Mr. Douglas is reported to have stated that he never had disease in his Tomato houses. This he attributed to making the soil firm, never using any artificial manures, and maintaining a dry atmosphere during growth. Regarding the firm soil and dry atmosphere, I fully agree with Mr. Douglas, but my experience is the opposite as regards manures, as I have found natural manures promote disease, and artificial ones the reverse. If Mr. Douglas would oblige by stating how he manures, it would interest many readers.—W. G. C.

## CHRYSANTHEMUMS.

### CULTURAL NOTES ON CHRYSANTHEMUMS.

No time should be lost in transferring the plants from the cutting pots to larger ones directly the former are full of roots. No greater harm can happen to plants than allowing the roots to become matted together. The object should be to keep the plants steadily growing from the time roots are formed to the time when the blooms are developing. The advantage of inserting the cuttings singly in small pots will be apparent when the first potting takes place. Instead of their feeling a check by the removal of the soil from their roots, as is the case when several cuttings are placed in one pot, the singly potted cuttings are transferred to larger pots without the least check to their growth. For the first potting a large shift is not necessary, pots  $3\frac{1}{2}$  inches in diameter being large enough. From these the plants go into others  $5\frac{1}{2}$  inches, and finally into 9-inch ones. Experience has shown that it is a mistake to employ large pots for single plants. Not only do they occupy unnecessary space, but the plants cannot be so liberally fed as when in pots of the size named. Chrysanthemum roots have such a tendency to run straight to the outside of the soil, that when pots too large are employed in the early stages of growth the inner part of the soil in the pots is not nearly fully occupied. The compost for the first potting should be carefully prepared. Loam is the principal ingredient in the compost for potting at any stage. The condition of this must be closely studied. While loam will in some cases be fairly rich, that from other districts may be exceedingly poor in quality. Such material as the latter re-

quires supplementing with manure of some kind. If the plants are potted in this material without the addition of manure, the growth will be weakly and devoid of vigour.

If the stems of the plants do not swell freely in their infancy, they cannot do so freely afterwards. My experience is that Chrysanthemums cannot grow too freely from the commencement. To two parts of poor loam add one part of well-rotted horse manure, one part of leaf-soil, silver sand and crushed charcoal, according to the nature of the loam. If the soil is not in any way impregnated with lime or chalk, add pounded oyster shells liberally. For convenience in potting rub the soil through a half-inch sieve. About three crocks carefully laid at the bottom of each pot with the rougher parts of the compost over them will suffice for drainage. If the soil is moist, as it should be when used, no water will be required for two or three days, when a good soaking should be given. Return the plants to the shelf close to the glass in a cool house where frost is excluded. Here the plants should remain until the roots run through the soil to the sides of the pots when a cold frame stood in a sheltered sunny spot will suit them best. Care should be taken to stand the plants on a thick layer of coal ashes, with the double object of raising the plants close to the glass and providing efficient drainage.

E. MOLYNEUX.

### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum La Pelle Blonde.**—Where varieties with fragrant flowers are in request, and they are encouraged by some societies, this incurved kind is worthy of attention. The blush-white blooms are pleasing.

**Chrysanthemum Miss Cannell.**—It may not be generally known that this pure white, single-flowered Chrysanthemum is very fragrant, and where prizes are offered for blooms possessing scent, it is a good sort to cultivate.—E. M.

**Chrysanthemum M. Gruyer.**—This Japanese variety was introduced to commerce in 1874 by M. Calvat, and is at once a great improvement upon Vice-President Audignier. The colour of the flower is light rose, shaded and tipped white. The habit is dwarf, a point in its favour. The blooms are of full size.—E. M.

**Chrysanthemum Rev. W. E. Dewfrey.**—This single-flowered variety possesses more colour than the bulk of kinds in this section, and for that reason is worthy a place in ever so limited a collection of this section. The individual blooms are deep crimson, freely produced, and valuable for decoration either in a cut state or growing upon the plants.—E. M.

## GARDEN FLORA.

### PLATE 1008

#### SENECIO LAXIFOLIUS.

(WITH A COLOURED PLATE. \*)

This is one of the numerous shrubby composites which constitute so prominent a feature in the flora of New Zealand. It is a native of the Southern Island, and was first collected on the Nelson Mountains by Mr. H. H. Travers. From this locality it extends to the Canterbury Alps at elevations varying from 2500 feet to 5000 feet. It was originally described by Mr. J. Buchanan in the "Transactions of the New Zealand Institute," November, 1869. It is a woody, much-branched shrub of neat habit, the leaves being of a greyish colour above and covered beneath with a yellowish white down, as are also the young branches and petioles. The inflorescence is a loose corymb, the flower-heads being about 1 inch across

\* Drawn for THE GARDEN by Miss Tisdale in Mr. Gumbleton's garden at Belgrove, Queenstown, Ireland. Lithographed and printed by Guillaume Severeys.

and the ray florets golden yellow. The name *laxifolius* may have been given at first in mistake for *laxiflorus*, which would certainly be more appropriate to the open corymbs borne on slender peduncles than the present one is to the foliage. With regard to the affinities of the species, it was stated by Mr. Buchanan to be nearly related to *S. Monroii*, but according to Sir Joseph Hooker it is much more closely allied to *S. Greyi*, a species which he described in "The Flora of New Zealand" upwards of forty years ago. From *S. Greyi* it differs slightly in habit, but chiefly in its smaller leaves; in other respects it is so near to that species, that it may be considered a geographical form belonging to the Southern Island; whilst *S. Greyi* itself is confined to the Northern Island.

It was originally introduced to Kew, and is now grown there. A plant, however, on the rockery has succumbed during the past winter. It is probably better adapted to the climate of the south-western counties and the south of Ireland. It is one of the many rare plants which grow in Mr. Gumbleton's garden near Cork, and it is from his plant that the accompanying plate and that of the last volume of the *Botanical Magazine* have been prepared.—W. J. B.

— This pretty free-blooming and perfectly hardy New Zealand shrub came to me between two and three years ago from the Royal Gardens, Kew, under the name of *S. Greyi*. When it bloomed with me in the open border last summer I sent the flowers to Kew, where they had not yet seen them, and on examination and comparison with the specimens in the herbarium it was pronounced to be *S. laxifolius*. It appears from the letterpress attached to the plate in the *Botanical Magazine*, No. 7378 (which was also prepared from my specimen), that it is very near to *S. Greyi*, which it may be said to represent in the Southern Island of New Zealand, as it (*S. Greyi*) is only found in the Northern. It forms a low-growing tufty bush, and blooms freely in quite a small state on the tips of nearly every strong shoot. As it stood the severest frost I ever remember here when the thermometer fell to 3, or 29° of frost, on January 4-5, 1894, without receiving any injury therefrom and without any protection save that afforded by a light covering of snow, it may be pronounced to be perfectly hardy.—W. E. GUMBLETON.

**The yellow Aconite.**—There are few places where the yellow Aconite is seen in such perfection as at Coleby Hall, near Lincoln. The borders everywhere are one mass of yellow, every foot of ground covered. On bright days when millions of flowers are open the sight is gorgeous and not easily forgotten, especially at this dull time of the year when hardy flowers are far from plentiful.—J. R.

**Erica codonodes and the recent frost.**—When observing the enormous number of ornamental shrubs which have been either killed or disfigured by the recent severe weather, it is pleasing to come across shrubs that have not only escaped, but are looking green and bright and even flowering at this time of the year. Such a shrub is *Erica codonodes*, which is now in full bloom in an exposed position at Messrs. R. Veitch and Son's branch nursery at Exminster, Devon. Neither large nor small plants have suffered in the least, while close beside them *Pernettya mucronata* and other shrubs are cut to the ground. Another handsome Evergreen in the same nursery is *Choisya ternata*, which has been very little injured. Just a few of the outside leaves are nipped by the severe cold, but the flower-buds are uninjured and look very promising.—F. W. M.

SENECIO LAZARIFOLIUS

## THE WEEK'S WORK.

## FRUIT HOUSES.

**POT VINES FOR NEXT YEAR.**—Most growers doubtless are in a position to purchase their fruiting canes from large growers who make a speciality of producing canes for hard forcing, and thus save time and secure a good crop. Others are not so fortunate, and my remarks apply to those who are obliged to grow their own canes, often under considerable difficulties as regards space and labour to devote to the work. I still follow the well-known practice of potting on what are termed cut-backs, or last season struck Vines, and repotting now should be finished if the canes are intended for forcing early. Some growers pot direct into the fruiting pots, others give two pottings—one in February or March, another the middle of April, but so much depends upon the size of the plants. If they are strong and were potted last season into 8-inch pots, they will now shift readily into the fruiting size. If, on the other hand, they are at all small, it is well to give two pottings. As most growers are aware, the Vine in a young state does not root freely till the shoots are somewhat advanced in growth, so that it is well to repot after growth is well advanced just at the time they commence to push out new roots. This commences when the new shoots are from 4 inches to 6 inches long. When repotting at this stage the compost should be of a suitable temperature, the pots clean, well drained, and the work done quickly in a warm house so as to avoid cold draughts, potting firmly, and leaving a good space at the top to hold water. I never advise the use of decayed manure in the final potting, as food may be supplied in quantities as required from the surface. On the other hand, I do not advise a poor soil. Good turfy loam that has been stacked some months with such additions as Thomson's Vine manure and bone meal will make a good mixture and promote a short-jointed growth. Some good growers advise bones as drainage, but I prefer to use them in a fine state in the soil, as if given too much water at any time before the pots are full of roots the soil soon gets sour. After potting, if a little bottom heat can be given, it is well for the plants, but not imperative. Careful watering at the start is essential and a light place near the glass. Syringe twice daily, giving a temperature of 65° to 70° by day with a free circulation of air to promote a sturdy growth, and 5° to 10° lower temperature at night, according to the weather. Ample supplies of food will be needed when the pots are full of roots and top growth robust.

**VINES PLANTED OUT.**—Much the same practice as that detailed above applies to Vines planted in a narrow or restricted border, and this mode of culture is better in many respects, as those with limited space or labour may with advantage get early Grapes at less trouble than with pot culture. I find it most advantageous, but it may be thought, why grow cut-backs when young Vines struck in one season may be fruited the next either in pots or in small borders? The truth is, we do not get sufficient sun to ripen the wood—in fact our seasons are too uncertain, and I find much better results are obtained from Vines struck one year and planted out or potted on the next. The planting-out system is good where there are small pits or low houses, as with the latter many more plants can be grown. It is not necessary to give the canes all the space. We grow pot Figs and such plants as require the same temperature as well. The compost advised for pot Vines is the same, and a root space of 18 inches to 2 feet is given, but the latter may be wider or deeper according to the means of the cultivator, and it is equally necessary to have plenty of drainage. By planting out now with what may be termed planting canes, growth is rapid, and there is no difficulty in getting firm wood by the end of the summer months. The planting differs from potting in this respect, the old soil is shaken away and the roots spread out carefully; hence the necessity of

doing the work before the Vines have made much growth, and to prevent a check it is well to start the young plants in a medium temperature to get strong breaks, as then it is an easy matter to give the newly-planted Vines more warmth. From Vines planted early in April there is no difficulty in getting ripe fruit in a little more than twelve months from date of planting, and such Vines may be cropped more freely, as they colour better with more root space. In planting it is well to have a firm bed, ramming the soil as the work proceeds and giving the roots a little finer material than the main body of the bed of the soil. Young cultivators may require more information as to the advantages of bottom heat, and if possible to apply the same. It is a great gain both at the planting and again when starting the Vines for early forcing. Such heat is not required in the summer or when a free growth is secured—indeed does more harm than good, as with a small border the roots dry readily. Those who have not the means to give warmth at the time named will find they obtain equally as good results, though it may take a little longer time.

**MELONS IN POTS.**—Early plants require abundant food at each watering, and manure may be given in a liquid state, or as a surface dressing in the form of a fertiliser. Pot plants, being restricted to a small space, require more food and should not be allowed to get dry, as with the lower roots in a dry state swelling ceases, with the result the fruits lack both size and flavour. Syringing the crop will now be an important part of culture. The plants revel in heat and moisture; given these two latter, red spider will be absent, there will be less fear of cracking, and the growth being free there is less disease. Temperatures may now range high, the night being 70° and 10° higher by day, with air on the top ventilators, allowing a rise to 90° at closing time. There should be no fall in the bottom heat; this should be at least 80°; and if the bed is kept moist there will be less need of heavy syringing, as there will be constant vapour and a healthy growth. In recommending syringing or watering of these plants the grower must take into account the structure in which the plants are grown, as close, small or sunken houses do not dry so quickly as large exposed ones. When damping down it is well to do it thoroughly, but lightly; there is no need to cause the water to run down to the roots, a slight dewing over being sufficient. Pot-grown Melons may be had of superior flavour to those grown on manure, as there is a greater command of the roots. There should be no delay in supporting heavy fruits and it is not necessary to describe any plan, as most growers adopt the means they consider best, but the less pressure there is on the fruits the better. In pot plants there is less pinching of lateral growth than with others, but it is equally important to pinch out all laterals after the fruits are swelling freely, as such growths rob the fruit. Top-dressing will be necessary, and such aids as decayed manure soil and bone-meal may be freely given, leaving the collar of the plants as free as possible. In case the surface of the pots is covered, rough pieces of loam may be used at the outside or round the rims to hold the new soil. It will readily be seen when the fruits stop swelling, and at that period it is well to water sparingly with pure tepid water only, as at that time flavour must be considered. More air will be necessary, but it is not wise to reduce supplies too quickly, as a Melon ripened in this way is rarely first-rate.

**SUCCESSION AND FRAME MELONS.**—With more sun-heat there will be no difficulty in getting a free growth, and no matter in what way the plants are grown, good results may now be expected. Successions may be grown as cordons or in the old form with two or three main shoots from one plant, but I do not see any gain except in saving of plants at the start or in the case of any variety one is anxious to fill a large space with. Many good growers advocate poor, very hard soil and little food at the start. I do not think it necessary in the case of all varieties. Some, I admit, that grow much to leaf and are bad setters

may require starving, but I think a sound or heavy soil with such aids as wood ashes and a sprinkling of bone-meal or fertiliser gives the plants a start. Many fruits are not worth eating by being grown on a mass of decayed manure. With restricted root space there is no fear of the collapse of plants where plenty of heat can be given. With plants grown on the extension plan the points must be pinched when a few inches above the trellis and two or four shoots trained over it, these shoots later on pinched, when lateral growth will push out, showing plenty of female flowers. The grower should endeavour to get as many set at one time as possible to prevent one or two stray or early fruits taking the lead, only to be removed and cause a delay of ten days or more. I have a great liking for the cordon system; there is less difficulty in setting at one time. It is a certain way to obtain an early set, and though more plants are required, the cost is so small it need scarcely be mentioned. For this method sturdy growers should be selected and planted at 15 inches to 18 inches apart, the growths restricted to one till the plants reach well up the trellis, when they should be stopped, and the first two fruits set which show on the laterals. Less soil is required by cordon plants. I have secured very good fruits in 6 inch pots plunged in soil or fibre. Such plants require a lot of food, but there is no trouble with canker and the crop is quickly cleared. Melons in frames are much grown during the summer months by those who cannot devote a house to their culture and excellent fruits have been obtained with very little means at command. Some years ago I grew a lot of fruits in frames that had raised early Potatoes without bottom-heat of any kind, but the soil was made firm and the plants were close to the light. I also found it advantageous to place slates or tiles if there was much manure directly under the plants to prevent rooting through into the manure, the evil with frame Melons being gross growth and difficulties of setting. Many could grow good Melons during the summer without bottom-heat by planting strong sturdy plants and by careful attention to watering. Now is a good time to prepare plants for this purpose, and they are best raised in frames or near the glass from the start. For frame culture such kinds as Blenheim Orange, Gulton Orange, Beauty of Syon, and Hero of Lockinge have a good sturdy habit. By sowing now there will be strong plants at the end of the month, and they will be ready to plant at a time we get long days with plenty of sun-heat. The frames should be covered at night to maintain an even night temperature, and it is not well to have the foliage wet at night. Damping and watering should be done early in the afternoon, closing with plenty of sun-heat. Beds for bottom-heat should be prepared, using plenty of Oak or Beech leaves in the stable manure, the material prepared by turning and placing in heaps in readiness for use, and in making the bed the more solid it can be made the more gentle will be the heat. Soil should be placed in hillocks as the heat declines a few days before planting.

G. WYTHES.

## KITCHEN GARDEN.

**SPINACH.**—Earlier in the year I advised sowing this vegetable between the rows of dwarf early Peas on sunny borders. The same plan has frequently to be adopted between rows of later Peas owing to scarcity of ground. Where, however, ground is plentiful, it will be best from the present time to the end of the season to sow on separate plots. Tall branching sorts of Peas so shade Spinach that not only is growth drawn and weakly, but the quality likewise suffers proportionately. Allow 15 inches between the rows and thin out freely, as if left thick the leaves do not attain to half their normal size and the crop runs to seed much sooner; 9 inches from plant to plant is a good distance. The Victoria is an improvement on the ordinary round variety, at least for sowing now and for the next three months. If an east border can be reserved for sowings during June and July so much the

better, as at that date this crop does much better with less sun and more moisture. All growing crops of this vegetable will be improved by an occasional sprinkling of guano between the rows.

**FORCING ASPARAGUS.**—If any more roots grown specially for the purpose, or those from old beds which are to be done away with, have yet to be forced, this will now be an easy matter. Where frames on hotbeds have been employed for earlier batches, they may, as each lot is cleared out, be refilled with fresh roots without any renewal of the fermenting material, as closed lights and increased sun heat will soon start the crowns into growth. I find leaf-mould as good as anything for covering with, the fibrous rootlets working into it with great freedom. Planting completed, give a good soaking with warm water to settle the material, and keep the lights closed till growth commences, when plenty of air must be admitted to strengthen and flavour it. When an inch high, a watering with diluted farmyard liquid, this being repeated in a week's time, will be most helpful. This, however, should always be followed by another of clear water as a cleansing agent. If there are more roots than can be at one time accommodated in the frame covering the hotbed, place them in an ordinary cool frame, keeping it close for a time. Here they will come on very gradually, but still in advance of the earliest outside beds. Where permanent beds, constructed especially for forcing and heated by manure linings, are still in cutting, care must be taken that the litter placed over the crowns is not too dense, as owing to more favourable weather and increased heat the grass will be liable to run up weakly. If the beds are nicely covered it will suffice. Where outdoor beds have not yet been seen to the manure should at once be raked off, the surface pricked carefully over, a dressing of salt applied for the eradication of worms and slugs, this being followed by another of some approved fertiliser. On very light sandy soils it is a capital plan to cover the surface at the end of April with spent Mushroom manure. This conserves the moisture and keeps the roots in a cool and equal temperature. In carrying out the work care is needed, or the fork may destroy many of the earliest growths. Any new beds intended for planting in April may well have the surface stirred several times to dry and sweeten it.

**EARLY VEGETABLE MARROWS.**—In February I advised sowing a few seeds of an early variety to produce plants for yielding a few early Marrows in May and June. Ours are now in 6-inch pots and have been removed to an intermediate house, placed near the roof glass. I generally grow a few in pots 12 inches in diameter, and train the growths to a wire trellis close to the front lights of a span-roofed Peach house. This latter position is necessary, as unless the plants have a free circulation of fresh, dry air blowing through and around them when in flower, the pollen does not dry and a crop cannot be secured. If potted in good sound loam no stimulant will be required until the Marrows are swelling, when it may be given at every alternate watering. Pinching and regular thinning out of the foliage will likewise be necessary. The remainder of the plants are planted into a frame on a gentle warm bed of Oak leaves, with a foot of good friable soil free from animal manure. When planted they are kept somewhat close for a few days, afterwards admitting air in strict accordance with the weather. Too much moisture either at the roots or by the use of the syringe is not advisable, as early Marrows are very prone to canker and mildew, particularly in dull, sunless weather. Many err in allowing too much lateral growth, this being the greatest evil in Marrow culture, as not only are the plants weakened, but small, puny blossoms are formed which seldom set. I usually sow the second lot during the first week in April. These are grown in comfortable quarters and finally planted out in the frame from which the earliest Potatoes are taken. Moore's Cream, Sutton's Vegetable Marrow and Penny-byd are all excellent where the smaller varieties are preferred. Long White and Green Bush are amongst the most profitable of

the larger sorts. The Custard Marrows are better adapted for sowing later on, to be grown under cooler conditions as the summer advances. In sowing the seed use small pots, placing two seeds in each and finally reducing to the strongest plant. A temperature of 60° is suitable, and 55° after growth has commenced.

**PLANTING EARLY SEAKALE.**—In southern districts where Seakale is expected early in November a few rows of prepared thongs may now be planted, the main batches following about the middle of April. Some time ago I advised the preparation of a sunny plot for this special lot and the exclusion of strong manure, which, especially in rainy seasons, induces a prolonged growth and late maturity. If the divisions have been laid in warm, sandy soil and have had frame protection, new growth will have commenced. On this account careful handling will be necessary, as the least touch will snap the brittle shoots. A calm day is best for planting the sets, as draught soon injures the new fibres which have formed while the cuttings have been lying in soil. The best mode of planting is to use a blunt-pointed dibber, making a mark on the same, so that all the holes may be of the same depth. Sink the crowns just below the surface and finally cover each with half an inch of leaf mould. This will shield the growths from frost until somewhat hardened. If possible allow 2 feet between each row and 18 inches or 20 inches from set to set. In levelling the ground afterwards use a fork, as raking the surface is apt to damage the new growths. If forward enough, reduce the growths to three on each set before planting.

**EARLIEST CELERY.**—Forward boxes or pans sown early in February will now be in a fit state to prick out. Nothing answers better than a frame elevated on a shallow bed of leaves. All that is requisite is just a gentle warmth at the roots until the plants are established. Make the soil firm, water the day previous to planting, and keep the young seedlings covered with damp Moss while the work is proceeding, so that the fibrous roots do not suffer. For Sandringham and similar dwarf varieties a little less space between the plants than that usually allowed to main-crop kinds will suffice. A little leaf-mould incorporated with the soil will induce the formation of plenty of roots and ensure the plants lifting with a good ball at planting time. If ordinary boxes are used, they should on the completion of pricking out be removed to a warm sunny greenhouse or similar structure, where after fresh roots have been made abundance of air can be given. From this place they may at the commencement of May be removed to sheltered nooks and corners in the open air and protected a little at night when frosty.

**MAIN CROP.**—I never advise sowing this in heat. An ordinary frame facing south and in a sheltered position is the best. Employ good loamy soil and pass the same through a rough riddle to remove large lumps and stones. Let the seed-bed slope gently to the sun, sow thinly, firming the surface with the back of a spade, sprinkle with tepid water and keep the lights closed and cover with double mats at night. Under this treatment the seedlings will soon appear, when a little air must be admitted, increasing it as growth proceeds. Thinning must be done as soon as possible, as nothing tends to spoil Celery so much as crowding the plants. Celery brought on in this cool way seldom runs to seed prematurely and stands removal to the trenches without exhibiting any signs of distress. As regards varieties, it is well not to confine oneself to one or even two. If the season is indifferent and bolting takes place in autumn, the cultivator is placed in a dilemma. Early Rose, Standard-bearer, and Leicester Red, the latter a grand sort that stands a wet winter without decaying, also Wright's Grove Red, may all be grown with confidence, while as a white sort to dig in November and December Wright's Grove White is hard to beat. That capital old Celery Ivery's Nonsuch Pink is still one of the very best. Where Celeric is valued in the kitchen, it may now be sown under the same conditions as ordinary Celery, or

during the first or second week in April beneath hand-lights in fine soil on a sunny border.

**FORWARDING FRENCH BEANS.**—A batch of Syon House and Ne Plus Ultra may now be sown in 4½-inch pots in good holding soil and placed in a warm greenhouse temperature until germinated, when an ordinary frame will suit them best. These if exposed in all favourable weather and carefully watered will have a hardy constitution, and be suitable for transferring to a warm, sheltered corner of the kitchen garden about the third week in April. Of course, they will then need protection, especially at night, and if a rough framework can be erected over the plot and covered with mats or canvas at night, no fear of injury need be entertained. About five Beans should be left in each pot. When planting draw out good wide drills and of the same depth as the balls. Do not single the plants out, but merely part the balls gently and press the soil firmly round the roots. In addition to the night protection, Fir or Laurel boughs must be placed here and there for shelter.

**PLANTING BROAD BEANS.**—If the advice given in February was adopted and sufficient seed of the Early Mazagan sown in pots or boxes, they will have had sufficient time for hardening off, and may now be planted out in warm soil and duly screened as advised for French Beans. Plant sufficiently deep to prevent them from swaying to and fro, and if the soil is at all dry, water gently home. These will afford many profitable pickings before those sown in the open ground come into bearing.

**HORSERADISH.**—New plantations may now be made on deeply trenched, highly enriched ground. Pieces 8 inches or 9 inches long should be dibbled in 15 inches apart, the crowns being left just level with the soil.

**MINT.**—Where the forced supplies are becoming exhausted and that in the open beds is not yet fit for picking, a few clumps may be taken up and placed on the border of a cool Peach house, surrounding them with soil. In this situation Mint will quickly grow and a break in the supply be avoided.

**MUSTARD AND CRESS** may now be sown under hand-lights in warm borders. If several of these are used, inside sowings may now cease.

J. CRAWFORD.

## GARDEN SKETCHES.

### CHAPTER X.

With an eye made quiet by the power  
Of harmony and the deep power of joy  
We see into the life of things.

WORDSWORTH.

**SEPTEMBER 3.**—Now comes the robin's sweet autumn song. I believe the redbreast really sings all through the summer-time, but that in these calm autumn days, when the song of other birds has ceased, we notice it the more; and somehow there always seems a tone of sadness in the little tender flute-like notes as they break through the tranquil air. They seem to tell us that light and warmth, that leaves and blossoms are receding from us, and no longer tripping onward with the vernal hours. But the rich sense of fulness and completion is ever present in the autumn air, and this makes the robin's song at once precious, and yet sad to us. We have had our joy, even if it be now departing, and we gather up the fragrant sunlit hours to lie embalmed in our hearts, and be drawn forth on many a darkened day, for the beautiful alone is imperishable, and having once had birth, though no longer visible, yet lives on for ever in the soul.

One of the prettiest morning sights is the circling flight of pigeons above an old farmstead seen in the valley. Again and again, with an upward sweep, they pass above the dark Fir

trees with the sunshine caught on their outspread wings. A flash, and they are invisible, as they turn in flight, and with a downward curve seem almost to touch the old roof-top, but instead, aloft they soar again, wheeling round and round, till in a moment they drop together, tired out with the joy of motion. The swallows are already preparing for their southern flight. They are congregating together, sitting along the eaves of the dwelling-house, and then rushing together through the air with loud twitterings. On the chimney-tops sit the starlings, since their young are reared and their "labour of love" is ended for the year, and down the hollow space of a sunny morning comes a sweet, low sound, that mingles with one's last waking dream. The little rippling notes are very touching, not clear or joyous, but "tender and true," sweet contentment with a simple lot: like the bird itself, unnoticeable except when brought near, when the lovely iridescent hue becomes visible on its burnished breast. The hedgerows are now rich in fruitage. Sprays of the wild Rose trees covered with scarlet hews are mingled with the glistening Blackberries, fruits for the birds and for the children, bound together in the thorny hedge, while the tall uncut branches of the Thorn hold the store-house of ruddy berries in safe keeping for cheerless winter days, when the frost-bound earth yields nothing to the hungry seeking beaks.

SEPTEMBER 21.—In the rock garden *Pentstemon cordifolius* is at present one of the finest bits of colour. Its long trailing branches, covered with deep crimson flowers, are spread out on either side. Some are lying across the blue grass tufts of *Dianthus* and some have fallen among the low-growing *Campanulas* that are sending up fresh blossoms; but wherever they have tossed themselves to, they seem equally beautiful. The dry, hot summer has suited this plant to perfection; last season, being damp and much cooler, it did not flower at all. Another good dry weather plant is *Zauschneria californica*. Its blossoms are bright scarlet, small, but borne in great profusion. Its sucker-like roots increase rapidly, pushing out on every side, and the plant soon becomes a large tuft. It can be readily divided at any season. *Plumbago Larpente* is in a sunny nook, with cool peat mould at its root. This is its most beautiful stage when the foliage changes with shortening days to a deep crimson hue, while the sapphire flowers are still in perfection. The winter *Jessamine*, forced on by the warmth, has blossoms ere the leaves have fallen. This *Jessamine* and the *Schizostylis coccinea* flowering together make a fine autumn group. The lack of moisture has stunted the *Schizostylis*, for though in bloom its flowers are small. Two beautiful-tinted foliage plants—*Shortia galacifolia* and *Galax aphylla*—are now at their best. The latter has leaves of claret colour. It is planted in leaf mould and loam in a deep rock fissure, so that although in the sunniest aspects its roots have been kept cool and moist during the summer heat. *Shortia galacifolia* is in a shaded position, with peat and leaf mould mixed in the soil. It, too, has its roots under a stone, while the leaves form a crimson rosette, but as yet it has not bloomed with me. In both of these American plants the foliage is persistent. *Hypericum repens* is still in blossom, and the changeful foliage as it passes to red and russet-brown makes it even prettier in autumn than in spring.

The golden passing away of Solomon's Seal makes a pretty group in a shaded corner, along with the *Osmunda Fern* that is putting on its russet robe. Among these we have just

been planting *Daffodils* in clumps that will awake earlier, and roots of the *Star of Bethlehem* (*Ornithogalum umbellatum*) have been added to give a silver gleam as the *Daffodils* fade. After many failures, *Daphne cneorum* is at last contented with me. Planted deeply in peaty soil and some pieces of rock set around the base of the stem, its roots have been kept cool during the drought, and thus it has been able to form plenty of fresh shoots each ready for its rosy crown of blossom in spring-time. Once well started, the spreading growth can be layered all round, and the plant thus assisted to carpet the ground with its fragrant garlands of blossom. The *Shield Saxifrage* (*S. peltata*) has withered away without its usual autumn glow, but the *Megaseas* have borne the sunshine unharmed, and the border of them around the *Periwinkle* bank is full of bronze and crimson leafage. A clump of *Pulmonaria officinalis* torn to pieces in June, and planted under the shade of evergreens, has completely covered the ground with its large, silvery blotched leaves. It is too coarse growing for a choice border, but any wild bit of ground that it can take possession of is just the place for it, and very welcome are the clusters of pink blossom that begin to peep out with the first warm days of January. *Mignonette*, the flower of the desert, has been especially fine this summer. Nothing can be more delightful than the fragrance with which it now lades the still autumn air, and is wafted across the lawn with every passing breath of wind. It is needful to make a sowing in June as well as early spring, as it soon becomes exhausted through seed-bearing, and the later sowing comes in sweet and fresh for autumn days.

In the walled garden *Solanum jasminoides*, though cut down by winter frosts to within a foot of the ground, has re-climbed the wall and flung itself over to the other side, bringing with it trails of white clustered blossoms. This is usually a greenhouse plant, but, given a warm dry position, it seems quite contented out of doors. The *Myrtles* have suffered much from lack of moisture. They have simply refused to grow and are just in the same condition as in spring, but *Coronilla glauca* has become rampant and also flung out long arms of blossom. The *Magnolia* on the hottest spot of the wall has made good growth. These *Lily* trees that come to us from east and west, from China and Japan, from North America, and also from the Himalayas are impatient of removal, and take a long time to recover any root-disturbance. The best time for transplanting is in spring, just as growth begins. When moved in autumn, the fleshy roots if injured will lie rotting in the ground all winter. No garden sufficiently favourable in situation should be without one of these glorious trees, where the *Lilies* of the pool seem to have been uplifted from their peaceful home, where they could wake and sleep on the tranquil bosom of the shimmering water, to be set henceforth amid the warm and glossy leaves as perfume cups to scent the passing gale.

SEPTEMBER 29.—To-day friends have been with me who have recently come to live in a new house with surrounding land, asking how they should commence laying out the grounds and forming a garden. Now to those who are fortunate enough to have the planning of a garden for themselves, I would say let them not think that there are any hard-and-fast rules as to beds and borders, and laying out walks and terraces, and plots of Grass, and planting ornamental shrubs. The first thing in forming a garden is to take a general outlook, and see what the situation most readily and easily lends itself to, and then to set to work and do whatever seems fittest and best in keeping with the

extent of the grounds and with the dwelling-house itself, and what afterwards will give least trouble to keep in order. One general harmonious idea perceived without effort, and yet rendered interesting from the variety of detail, which gradually becomes evident to the eye, is what I think we should try to aim at. Walks are frequently so meandering, and flowers either so mixed or scattered, that the one precious thing a garden should ever have to offer us, rest for mind and spirit, is wanting. If it be possible, let us have in our garden a cool and shady walk for summer's hottest days and meditative hours; such a walk as in winter will afford us shelter from the cold blast, and where we will ever find the earliest *Primrose* of the year. An extent of well-kept Grass, be it large or be it small, should be always present in a garden, were it only for its delicious fragrance during summer-time when freshly mown, not to speak of the cool velvet carpet it forms to tread upon. Many narrow walks are a weariness, for of all places it is just in them that weeds most heartily rejoice, and much labour is wasted keeping them in order. And now as to the placing and arranging of plants. "Art in the garden" may appear to some a false phrase. They think that Nature is supreme, and that the less she is interfered with the better. In a sense this is no doubt true, and Nature when left to herself is ever beautiful, and nothing we can do can approach the magic touch by which she decks the hills and dales, clothing the mountain side with the sturdy Oak or dark Pine tree forest, and casting a mantle of purple around the more rugged heights, where only the close-glowing *Heather* can withstand the rude winter storms, while through the valleys soft pasturage runs and creeps into verdant plains.

Yes! Nature left alone works with a master hand, and if we would do any good work in the garden we must read in her grand, open book and listen to her teaching in the woods and dells and by the streamlet's bank. There she sows and plants; in the garden it is we who plant and sow. Therein lies the great difference, and here it is that "art" steps in and enters by the garden gate. For what is all art but the sense of and intense feeling for the beautiful, which, having passed through the human mind and receiving from the soul the divine or immortal touch, desires to create itself afresh by expression what may, in other words, be called the finer adjustment of speech or delineation to that which answers within? Now the true artist, when painting from Nature, does not sit down and copy every leaf on the tree before him and paint things just as they are, for art is never imitation. No; he becomes imbued with the beauty of the scene, and then he endeavours as best he can to tell us his sense of that beauty and not mere facts about Nature; and just in proportion to the truth of his portrayal of that sense does he become a good artist, and what he omits, or, rather, what he refrains from painting and merely suggests, will be a most important part of his picture: for this critical faculty of choice or selection is one of the subtlest in art. And herein I think is the explanation of the old Greek adage, that "the half is more than the whole" so contrary to the mathematical axiom that "the whole is greater than its part." A poet with this Greek feeling has sung to us the same thought—"Heard songs are sweet, but those unheard are sweeter still."

But what has all this to say to gardening may be naturally asked. Well, as the scattered flowers by the mossy bank, the woodland way, the hillside slope or rocky gorge, are pictures ready for the painter's brush, for the poet's song,

or the soft dreams of music, so, too, should our gardens be full of pictures, and our flowers placed and arranged in the most beautiful way we can imagine. One reason why the bedding-out system is now giving way to the finer growing and grouping of hardy plants is that it was so uninteresting. Every garden was a copy, more or less, of its neighbour. No garden expressed its owner's individual love for plants, either in choice of different flowers or in modes of growing or arranging them.

But the greatest defect of all in the bedding-out system was that you could see it all at once. Bed after bed of colour, row after row of different hue, all spread before the eye at the same moment, nothing withheld, nothing reserved.

Now, given a good border of old-fashioned flowers sufficiently wide for grouping and sufficiently long for variety, the surprises and change of flower pictures as one passes along, step by step, are truly astonishing; and the most delightful part is, that these flower pictures alter in form and colour every few weeks of the year, and that there is not a day in winter even, save when the ground is frozen or clad with snow, that one cannot gather a bunch of blossoms fair to see. The charm in a border like this is its mystery and expectancy; you cannot see it all at once. Many of its prettiest groupings are hidden for the moment and you come upon them slowly, only seeing at first far-off glints as you pass along.

To plant such a border effectually one ought to study Nature's grouping, and notice how when left alone the flowers form little colonies. This arises from the original plant shedding its seed around, so that fresh young plants are always rising up round the parents, which after a little time gradually exhaust the soil and perish, leaving their progeny moving slowly onwards. So we will find that a good bold group or two of one kind of plant will look much better than repeating the flower constantly at intervals throughout the garden. L. A. L.

(To be continued.)

## FLOWER GARDEN.

### ROCKETS.

THE accompanying illustration is a pretty reminder that the sweet old Rocket, a flower most of us have known from our earliest days, still has its admirers, although it is all too scarce in gardens generally. The time when Rockets bloom is a lovely one, for the early summer flowers are gay in great variety. Then especially are the simple roadside cottage plots so bright and sweet, when Rockets spring out from carpets of Pinks and Pansies and lift up their tall spikes to meet the drooping clusters of the Monthly or Maiden's Blush Rose. Happily this flower is much loved by cottagers and it will linger long among them, but in larger gardens we seek it in vain—it is neglected. This neglect arises not from lack of appreciation of its beauty and fragrance, but because, although in every respect a hardy plant, it does not go on growing and flowering year after year. It wants a little special attention, and this to be given at the right time. If left to grow and extend as most hardy things do, it resents such treatment and soon disappears. It should not be included among the true perennials, as it cannot be treated like them, and yet there are many pretty ways in which it could be grown. The essential thing is to always have young plants. Although occasionally a group may stand a second season, the safe way is to

always have a batch of young plants. These may be raised from cuttings, which root readily even in the open ground if shaded from bright sun, whilst another excellent method of keeping up a stock is to take up and divide the plants as soon as they have ceased to bloom, replanting them in another spot. In a well-managed garden there should be a reserve plot where stocks of this and kindred flowers requiring similar treatment might be raised. With such an aid much could be done to reduce the number of tender plants still put out in gardens and show the best flowers of each season in the most perfect way. There are several distinct forms of the double Rocket varying in colour from pure white to lilac, all of them pretty, sweetly scented, and worthy of the best care and culture.

**Arnebia echioides** (the Prophet Flower).—This interesting perennial may now be increased

Border with old double Rockets. Engraved for THE GARDEN from a photograph sent by Mr. S. W. Fitzherbert, Lanscombe House, Torquay.

by those desirous of adding to their present stock. In average winters by the end of February the plant has again started into growth. Like many of the rarer perennials, this cannot always be divided to advantage, so that in this instance root cuttings are best resorted to. It is true also that the plant comes from seed, but in seasons like that of 1894 seeds were not abundant; indeed, at the best of times the capsules only contain one seed each. These seeds are very hard and germinate slowly, so that it is best to employ both methods where a stock is desired. The chief advantage of root cuttings in such a case is that plants are more quickly obtained, as the growth of these root pieces may be hastened by placing them in a close warm greenhouse with a temperature of 50° or 60°. Lift one strong clump from the ground and secure as many roots as can be spared. Having cut into short lengths, place them around the inside of some medium-

sized pots and fill in the soil. The root cuttings should be buried their full length, leaving the upper surface uncovered. A good way of staying evaporation is to plunge the cutting pot in one two sizes larger, fill round with sand or cocoa-nut fibre, and cover with a piece of glass. Under these conditions growth will issue from the apex in a few weeks.—E. J.

**Primula obconica.**—I enclose with this note flowers of this Primula in which you will see a great difference. One, the smallest flowered, is the true type and the other two are variations, in which the flowers are much larger, and some of them show a dark carmine shaded eye which helps to make them attractive. Some time ago an idea was expressed in your pages that this Primula was being improved, and, on the face of it, it looks so, but I think we shall not get much further in this way, for though we always get a good proportion of these larger and more highly coloured flowers from each batch of seedlings, we cannot depend upon them, and there is little or no advance on the best flowers of former years. This is unfortunate, as they are just as free-flowering as the type and more attractive, but I find them very shy seed-bearers, and invariably have to go back to a plant that has borne flowers of the typical size and colour for most of the seed.—J. C. TALLACK.

**Daffodils in the Grass.**—The warm sunny days of last month brought the Daffodils up rapidly, and on the 25th the Tenby variety was blooming abundantly, tall and handsome as before. Two special tufts were mentioned last year as producing sixteen flowers each, the result of two bulbs planted eight years previously. This year one has eighteen flowers, the other sixteen. The Scotch Daffodil had a few flowers out at the same date, also *Narcissus nanus* and *N. minor*.

**Alstroemeria seed.**—About a year ago I sowed some seven or eight seeds of the above, which I had kept for several years past in an ordinary paper packet. A few weeks later several seedlings appeared, and, as I imagined, each seed had grown. In December, 1894, when sharing the plants with a neighbour I found that while the larger plants had grown and produced large fleshy tubers several inches long, three of the seeds had only just broken into growth. These latter, strangely enough, were singularly alike in the growth they had made, each with its tiny shoot only about a quarter of an inch long and a root quite half an inch in length. Thus in the first instance the seedlings appeared as quickly as could have been expected from new seeds, while the latter remained dormant for many months. Some seeds are by no means impaired in vitality by keeping them, and will germinate as quickly after ten years as though quite new. But to ensure this I think one

condition is necessary, namely, a comparatively air-tight vessel or package and uniform temperature.—E. J.

### CROCUSES AT LONG DITTON.

THE forms of *Crocus aureus* and *C. vernus* are the familiar kinds one sees in most gardens, but many other species embracing pretty shades of colour deserve extended cultivation. At the present time (March 13) they are a pretty feature in Messrs. Barr's nursery at Long Ditton, where the collection is a very large one. Owing to the prolonged frost having kept the winter-blooming species at rest, those which in an average winter open their flowers in January are now blooming along with those whose season is the present. *C. imperati*, for example, often flowers at midwinter, but is only now in full beauty. It is a most distinct Crocus when closed or open, the closed flowers being beautifully

feathered externally with dark purple, and when open in the sun they are of a clear mauve or lilac shade. *C. biflorus* varies in several pretty ways, and one most distinct form of it, called *estriatus*, has a fawn-coloured base, but when expanded is of a pale lavender hue. Another form of *biflorus*, named *Weldeni*, is deeply feathered with purple externally through the lower half of the flower and white when open. *C. biflorus Pestalozze*, an Italian form and the smallest of this lot, is wonderfully free blooming, each bulb throwing up a cluster of several flowers, which, though so minute, have a charming effect. In colour they are creamy white. *C. Balanæ* is a striking species, the buds when they first appear being of a deep maroon hue, shading to bronzy yellow as they expand. *C. Tommasinianus* in great quantity was wonderfully profuse in blossom, and a long bed of it alone produced a fine effect. The flowers are large, of a deep purple-blue externally, shading to the palest mauve as they expand. A kind so free and beautiful as this ought to be plentiful in our gardens. *C. chrysanthus*, a yellow-flowered species, shows much variation, and several most distinct forms have been selected, one with a large clear yellow flower exquisitely scented, others curiously feathered and stained with brown externally, whilst one named *albidus* is a pure cream-white with a few feathered markings at its base. The stigma of the flower in these varieties is almost scarlet. *C. Suterianus*, clear rich yellow; *C. stellaris*, bright yellow, with feathered lines of dark brown; and *C. Olivieri*, deep orange-yellow, with short rounded petals, are all distinct and desirable species.

Many of these Crocuses might be easily naturalised about our gardens, and being wild forms would show less deterioration than the named garden forms of *C. vernus*, which sometimes get weak when left to themselves. Little groups in choice spots, especially in the rock garden, would greatly add to the interest and beauty of the early days of spring. A. H.

#### FLOWER GARDEN NOTES.

**PROPAGATING.**—When penning the notes on propagating that appeared on page 198 I did not know that the recommendation to make a careful inspection of the stock, with the view to find substitutes for any portion of the same that might happen to be scarce, would be very applicable this year. In many places where provision for the accommodation of a large quantity of tender bedding stuff is not of the best heavy losses are chronicled, and the experience is not uncommon to find only a very few plants left of some particular variety of which a large quantity was required. Under such circumstances the gardener is fortunate who is able to fall back on a good batch of such herbaceous plants as are suitable for the formal garden, but, failing these, no time should be lost in seed sowing. It is full late for this work, but if a little heat is available, *Petunias*, *Verbenas*, *Phlox Drummondii*, *Golden Pyrethrum* and *Lobelias* will not be long coming up, and a little extra attention must be given to push them on as fast as possible from the seed-pans. The Sweet Tobacco again will come up and develop quickly into good plants if these are pricked out of the seed-pans as soon as they can be handled. Tuberous *Begonias* are likely to be in great request, and if a batch of seed was sown as advised in January, the seedlings will by this time be nice little plants, with the corms rapidly swelling. They will make a nice display in mixed beds if the certain dissimilarity in colour, height and habit inevitable in seedlings is not objected to. If a good stock of bedding *Tropeolums* is to hand, they can be propagated freely (good plants being very quickly obtained) to take the place of scarlet *Pelargoniums*. Much may also be effected with the best and most enduring of the annuals that can presently be sown out of doors where they are to remain, such as *Linum grandiflorum*, *Tagetes*, the new *Linaria* and the white and purple *Malope*. Here alone are five different shades of

colour that can be relied on to last well through the summer. A season like the present, when the loss of tender bedding stuff is causing considerable anxiety, should act as a strong incentive towards the increased cultivation of hardy plants. Given plenty of *Pinks*, *Carnations*, tufted *Pansies*, *Pentstemons*, *Pyrethrums*, *Antirrhinums*, *Spiræas*, herbaceous *Lobelias* and the best of the annuals, a garden can be made very bright without the trouble of filling houses and pits for eight or nine months with so-called bedding plants.

**CARNATIONS.**—These have come safely through the winter and are now fairly on the move; a few old plants left over from last year have succumbed, but in the case of young plants no loss has to be chronicled. I notice a statement made recently, in answer to a query as to which can be styled true border Carnations, that there was no distinction: all might be fairly classed as such. I do not quite follow the conclusion; it is certain that there is a wide difference in varieties both in constitution, in general habit, and in the freedom with which flower is produced, and only those that can be classed A 1 in this respect should, to my thinking, come under the heading of true border sorts. I know of a few novelties acquired occasionally, some by no means came up to these requirements: they were a long way behind the old standard varieties that have always given satisfaction. A feeling of envy is engendered at the contemplation of the photograph in THE GARDEN (March 23). A bed of this size and thoroughly well furnished must be very beautiful. It seems that individual blooms of *Ketton Rose* last longer than those of most varieties, but this may be due to the retention of the perfect flower right through to the decaying stage owing to the total absence of splitting. This variety is a little longer getting established than some of the more fleshy succulent sorts, and, together with *Countess of Paris*, is put down about a fortnight earlier than the main batch. Where *Carnation* beds are not already mulched, they will be all the better for a coating of spent *Mushroom* or peat moss manure, especially if a bright sun with drying winds is likely to prevail.

**WINDOW AND BALCONY BOXES.**—If materials for these are ready, they may be planted at any time, especially if an early display is expected and a certain amount of hardening off is required. *Cobæa scandens* sown in warmth in January is the very best climbing plant that can be grown, and may be planted at the back of boxes for that purpose. The free-flowering *Fuchsias*, *Heliotrope*, *Begonia semperflorens*, and *Chelsea Gem Pelargonium* are good plants for filling up the remainder of the box with, and as trailers use the Ivy-leaved *Pelargoniums*, the blue and white trailing *Campanula*, and *Ball of Fire Tropæolum*. Somewhat similar plants can be used for window boxes, and in addition *Petunias* that rank among the very best window box plants. If the variegation introduced in the *Pelargonium* is somewhat stiff and formal, a substitute may be found in the shape of the fine bright-foliaged *Eulalia japonica variegata*, that is one of the plants that can be put in almost any position, and that will form an admirable companion to the *Fuchsias*, *Begonias*, and *Heliotrope*. Plants intended for vases may be pushed along so as to secure good stocky stuff by the time it is safe to plant. I think the practice of using one class of plants for each vase except perhaps something at the extreme edge as a trailer is to be recommended. Thus *Fuchsias* of drooping habit, as *Mrs. Marshall*, *Beauty of Summer* and *Wave of Life*, make beautiful vase plants. Main shoots may be supported to make a full centre and then the plants allowed to grow as they like. So, too, if Ivy-leaf *Pelargoniums* are used a few stiff *Pea* twigs can be inserted that the plants may run up to a foot or rather more in height, when they may be left to their own devices, with the exception that as they ramble a little stopping may be necessary if the plants are likely to get ragged. Where things of more formal habit or upright growth, as *Pelargoniums* or *Marguerites*, are used outside, plants as trailers are absolutely essential, and those recommended for similar positions in

window and balcony boxes can be used, the green and golden forms of the well-known *Creeping Jenny* being also capital trailers. In the list of subjects of drooping habit recommended above I omitted to mention tuberous *Begonias*. Seedlings discarded from the beds because of this habit can always, provided they are free and vigorous, be saved for vase work, the very pendulous form, which is an objection in the one case, being a pleasing and welcome feature in the other.

**HARDY SHRUBS.**—In answer to Mr. Smith's stipulation that perfectly hardy as opposed to crippled shrubs should be prominently named as having come safely through the February of 1895, I may mention in addition to the common *Holly* the *Minorea Box* and *Osmanthus ilicifolius*. I fear, however, in a season like the present one can hardly help referring to many plants that have suffered from the fact that in many cases one has hardly ever experienced anything of the kind before. Many trees, the conifers especially, are so disfigured, that it is a question if they will ever recover. E. BURRELL.

Claremont.

**Iris sindjarensis.**—This, one of the newer additions to the *Iris* family, is clearly allied to *I. caucasica*, having the same characteristic growth and foliage. It is an early flowerer, the first flowers expanding only a little later than those of *I. reticulata*. In colour they are deep blue, shading to pale sky blue, and possess a delicate scent.

**Jacks.**—These are large-growing, robust, single *Carnations* hawked by the costermongers under this name, and finding a ready sale because of their gross and robust appearance. When they bloom they are, of course, disappointing, but they fill up the garden and they are cheap. A few days ago I saw at Feltham a piece of 50,000 *Jacks*, and it was computed that at least 38,000 of them were dead. Planted out as seedlings last summer in somewhat richly manured ground, they made a most robust growth, and by Christmas were soft and sappy, showing the presence in the leaves of the spot, a brown fungoid-like growth that destroys the foliage. Then came the intense frost, with the result above named. Many of the 12,000 presumed to be alive are so injured that they are not saleable. But the enormous demand for *Jacks* is shown by the fact that one grower alone grows quite 50,000.—R. D.

**Iris susiana.**—"R. D.'s" experiences (p. 209) with the above are not exceptional, special treatment being required for the successful culture of the *Cushion* (*Oncocyclus*) section of *Irises*, to which division *I. susiana* belongs. After flowering a period of absolute rest is necessary, which in this country during an ordinary summer it is impossible to ensure without artificial means. I have grown *Iris susiana* and flowered it fairly well in mounds of soil raised a few inches above the ground level. The soil, a sandy loam, was made quite firm and the rhizome planted an inch below the surface. After flowering had ceased, bell-glasses were placed over the plants until the commencement of October. These prevented any direct rain from coming in contact with the plants, and the mound being raised about 6 inches above the rest of the bed kept the soil about the roots from becoming waterlogged even in heavy rains, though doubtless at such times some amount of moisture rose from beneath. In 1888, after the dry summer of the preceding year, these *Irises* flowered very well; in other seasons they flowered fairly, thus showing that a dry state of the surrounding and underlying soil is necessary. The roots are perfectly hardy, and during the winter months do not need protection except from stagnant moisture, and this is prevented by the elevation at which they are planted. "R. D." must not expect success at the first, for all the *Cushion Irises* are very impatient of root-disturbance and may probably refuse to bloom the first year. I have never grown these *Irises* in pots, but there is no reason why "R. D." should not continue to try this method of culture, remem-

bering that he must roast the rhizomes during the summer and give plenty of water, it being understood that the drainage is good, while growth is taking place.—S. W. F.

## ORCHARD AND FRUIT GARDEN

### HARDY FRUIT PROSPECTS.

In this district things look anything but cheerful for an abundant fruit season. Strawberry plants are very bad indeed, as during the early part of February when we were having such cold nights the sun was bright during the daytime, which soon melted the little snow that fell, leaving the plants exposed to the full rigour of the winter's blasts. The consequence is there is not a green leaf left on many of the varieties, and some of them appear to be killed entirely. Although we have had a week of spring-like weather they do not show the least signs of life. The only plants that present anything like a respectable appearance are those which were planted out of small pots last August, and though the leaves of these are for the most part killed, the crowns seem plump and are swelling, thus showing the more vigorous the plants the better they were able to resist the cold. Plants, too, on warm borders that had only stood one winter seem to have succumbed to the severity of the weather. Such varieties as Anna de Rothschild, A. F. Barron, Scarlet Queen, and many of the newer kinds seem to have suffered the most. It will be interesting to learn how others have fared in this respect. At no time had we in this district more than 2 inches of snow, and that soon melted in the bright sun even though it was freezing in the shade. Some plants of Loxford Hall Seedling on a north border seem to have withstood the frost far better than those on the south borders and in the open quarters, as these were covered with snow till the thaw set in. Doubtless most things will have suffered more in the south than they have done in the midlands and farther north on account of the small quantity of snow that fell in the southern districts and the bright sun experienced during the daytime. Raspberries in the open quarters seem to have all their buds killed, especially on strong canes that were not thoroughly ripened. We have had this occur before when scarcely a bud on those in sunny positions made a start, the canes having to be cut back to induce them to push from the bottom buds, while those on a north border have grown away freely. It seems to me that the constant freezing and thawing have more effect on plants than a long-continued spell of frost. I have often noticed that vegetables on a south border have suffered more than those on the other side of the wall, for while the one remained during the continuation of the frost below freezing point, the other through the action of the sun became thawed every day. This season has been no exception in that respect, for a patch of Turnips in the open quarters was all killed, while those on a north border have withstood the frost remarkably well. In the north the weather is certainly not so hot so early in the season, for during the last few days the thermometer in the day has reached nearly 80° in the sun, while in the valley it has run down to near freezing point most nights. Such weather must have a telling effect on plant life. Reverting again to fruit, Gooseberry bushes have suffered much from the attack of small birds, which are very numerous in this district. Many are quite denuded of their buds and will have to make a fresh growth from the old

wood. It seems curious, but while the severe weather lasted they did not attempt to touch them; it is only since the frost went that they have made such sad havoc. Plums and Damsons have suffered much in the same way, scarce a flower-bud being left. Pears so far are looking well, but I fear both Apricots and Cherries have suffered somewhat through the severity of the weather, particularly the former, for on cold heavy land such as ours the trees make strong wood, which does not always become perfectly ripened, and when severe weather sets in the gross shoots are often killed. Figs that were not covered present a pitiable sight, for the young wood is entirely killed, so that a season's growth will have to be made before they recover themselves. H. C. P.

*Busted Park, Sussex.*

### APPLE WARNER'S SEEDLING.

THIS is a really good kind and one that should be grown in all gardens where late cooking varieties of the best quality are required. The value

*Apple Warner's Seedling. From a photograph sent by Mr. Norman Blake, Bedford.*

of late cooking Apples is often overlooked, and for private gardens, if some late kinds were substituted for those that come fit for use in the autumn, it would be a great gain, as we have a wealth of fruit at the season named and but a limited number in April or later. Although it may be thought we have abundance of imported fruits, I do not hesitate to affirm there are none equal in cooking qualities to the one named. The subject of this note must not be confounded with that excellent variety Warner's King, a kind which has got quite a dozen synonyms, showing at a glance how popular it is. I am not suffi-

ciently acquainted with its history to know whether the same raiser introduced Warner's Seedling also. Probably he did, as the growth of the two are much alike; but the one is an autumn fruit, being at its best in October and November; whereas the seedling keeps well late in the spring and is of splendid cooking quality. Indeed, Mr. Warner gives the seedling first place for quality and keeping over other kinds. This fruit first came under my notice at the great Apple congress held at Chiswick in October, 1883, Mr. Warner, of Broomfield, Chelmsford, showing this variety, which was much noted by fruit growers as a valuable culinary fruit, and being grown on poor loam on a wet, clay subsoil showed its free-growing qualities. The fruit in question was gathered too early to test its quality, as late Apples should be allowed to remain on the trees as long as possible. The fruits are large, of good shape, greenish yellow at this season, but in autumn when gathered of a much darker shade of green and slightly flushed with red, hard and solid, with a brisk flavour. They retain their acid flavour well into spring. The trees bear well in any form, excellent results having been obtained by grafting them on healthy stocks which produce worthless kinds. As the season of grafting is close at hand, those who require late fruits should give this a trial, as it is a splendid cropper. So far I have not seen the least sign of canker or disease in either bush or standard trees.

As regards cropping qualities, this variety much resembles Bramley's Seedling, and is equally meritorious, but Bramley's is quite distinct, being flatter in shape and having more colour. I name Bramley's Seedling, as I have seen it shown as Warner's, and *vice versa*, and the mistake is readily made with kinds similar in size, quality, and keeping properties. The better-known Warner's King, or, as it is often called, Nelson's Glory and in many counties D. T. Fish, is probably one of the most popular kitchen Apples grown. It is a great favourite with exhibitors, and at the Chiswick conference noted above was staged in 150 collections, the fruits in many cases being very fine. I feel sure that the newer seedling will prove equally valuable when its good keeping properties are considered, as, like Warner's King, it is equally prolific, does well in most soils and situations, and, taking into consideration its freedom from disease or canker, I should place it among the most useful kitchen Apples. Although we have so many varieties, there are none more worthy of a place even in a limited selection than the above.

G. WYTHES.

**Colour in Apples.**—My experience coincides with that of "E. M." as to the influence of iron in the soil on the colour of Apples. Our soil here has a large natural supply, and even the greenest varieties put on a little colour, but another factor not mentioned by "E. M." is wind. In 1891 we had much wind in this part, and the colour of all Apples was much deeper than usual. Such varieties as Bramley's Seedling, Ecklinville Seedling, Stirling Castle, and others were beautifully tinged with red—in fact, more highly coloured than in the hot, bright, sunny season of 1893. The stock also exercises an influence on the colour of the fruit. The most remarkable instance of this that I ever saw was at the Guildhall show held in London some years ago. While judging some nurserymen's collections of fruit, my colleagues and I came upon a basket of Apples named Warner's King of a lovely red colour which was so rich, that if it had not been for the size and true Warner's King shape we should have put it down as wrongly named. After the show was opened I sought out the exhibitor

(Mr. J. Watkins, Pomona Nurseries, Hereford) and inquired the cause of the extraordinary colour. The answer was, that having some trees of Red Bietingheimer that failed to crop well, he cut the head off and grafted with Warner's King with the result stated. The expert fruit grower, Mr. Crump, Madresfield Court Gardens, turns out something like 2000 trees per year for Lord Beauchamp's tenants, and he informed me a year or two ago that he selected pips from the most coloured Apples for raising stocks. Those who have seen the well-grown trees he turns out and the produce they yield will agree with me that no more highly coloured fruit is grown in this country, and as proving the influence of the stock, the same finely coloured fruit is produced on trees sent out to his lordship's tenants in different counties.—W. G. C.

**Pear Beurre d'Arenberg.**—I was glad to see the illustration at page 111 of that very excellent winter Pear Beurre d'Arenberg. At Holme Lacy the trees that succeeded the best were worked on the Pear stock and grown against a south wall. It was, therefore, something of a surprise to me to read in the descriptive note at page 111 that this Pear succeeds well whether worked on the Pear or Quince stock. What is other growers' experience with this Pear on the Quince stock? My experience is decidedly against it. Is it also a Pear for standard culture? It might bear freely, but the fruit would be very small, unless in exceptionally favourable districts. At Holme Lacy the fruits grew individually larger than generally seen. I remember the late Mr. Haycock was much impressed with them, and asked me to let him have some grafts. Against an east wall, although the tree fruited freely, the fruit never ripened, also being small.—A. YOUNG.

#### SEEDLING APRICOTS.

THE branches on seedling Apricots certainly do not commence dying away so soon as on trees raised from buds or grafts. At the same time there is a slight disadvantage in depending on seedlings, because they are a year or two longer in coming into bearing, and the only way to make the trees fruit early is to lift them every year and replant again in rather poor soil. This unfortunately prevents them making a strong growth, but one has to bear with this to secure an early fruiting tree. I do not wish to make it appear that as the trees get older some of the branches do not die away mysteriously as on grafted trees. What I wish to show is that seedlings hold out longer, and after they get well established they fruit as freely and retain a greater vigour than grafted plants. At the present time I have a fruiting tree of the sort known as Large Early. This tree is seven years old, and the branches reach to a height of 16 feet on a wall with a south aspect. A more vigorous or productive example no one could wish for, as at present there is not the slightest indication of any of the branches dying away. From previous experience in this direction I should not like to say that such a thing will not take place as the tree gets older.

Having dealt with seedling Apricots in two gardens where the character of the soil is quite opposite, one being badly drained, with a heavy subsoil, the other a fairly heavy loam 2 feet in depth resting on a bed of gravel, I feel quite convinced that the latter soil is best suited to the Apricot, as the plants fruit earlier, the leaves are larger and of a deeper green. To raise the plants I place the stones singly in 5-inch pots early in the spring and bring on the plants in a greenhouse temperature, planting them out close to a warm wall in July. At the end of the autumn the young plants are 18 inches to 2 feet high. In the spring I cut them down to within 9 inches of the

ground; the next year I select five of the best-placed shoots to form the groundwork of the tree. At the end of the second year's growth the trees are replanted. After this I never prune more than is necessary to secure sufficient growth to fill up the wall space, as I am satisfied the less Apricot trees are cut about the better. There is this difference, however, between seedling and grafted trees, that the former do better when root-pruned, and will even then make wonderfully vigorous growth when they are grown in a favourable soil. The Moor Park variety is the last I should think of increasing in this or any other way. At the same time I have found that seedling plants remain longer healthy than when they are obtained in the ordinary way. I have had budded plants lose nearly all their branches the first year after planting, but seedlings invariably go on much longer. The Moor Park is certainly the most disappointing in that way. So far as my experience has gone, the Peach Apricot and Large Early are the most reliable sorts to raise from seed.

J. C. CLARKE.

#### GRAFTING ORCHARD FRUIT TREES.

THE grafting season having again arrived, it may possibly be of interest, and also profitable to orchard owners, to remind them of the folly and waste of allowing young, vigorous, but worthless trees to keep on cumbering the ground, when they might be made to produce good crops of excellent fruit in a few years by grafting them with select sorts. There are thousands of poor useless Apple, Pear, and Plum trees that never bear a decent crop of fruit, and probably never will if permitted to go on as at present, and it is decidedly to the interests of the owner and the nation that all such trees be made to bear good fruit and prove a profitable investment to the planter or his heirs. In almost every part of the country a reliable man can be engaged to graft trees at a fixed wage per day, or so much each graft. In this district the rule is to pay a penny for each graft inserted. Grafting is such easy and simple work, that any man of ordinary intelligence can soon learn how to do it. Many practical men advise sawing off the limbs some little time prior to inserting the grafts, asserting that success is more assured thereby. This theory, I believe, is not founded on actual fact, as I have for years sawn limbs off, and grafted at once with scions cut at the same time from other trees near, rarely having a graft die. If grafting wax is employed, the work is performed more expeditiously, but, failing that, any good clay, mixed with about one-third of horse droppings, well mixing the whole together, will answer almost equally as well. Some tie Moss over the clay to prevent cracking in hot weather, but if the clay has been properly prepared, there is little danger of that occurring. The following are good Apples for grafting on standard trees, and may be depended upon to produce heavy crops of fruit valuable for home consumption or market. Kitchen: Bismarck, Bramley's Seedling, Warner's King, Beauty of Kent, Mère de Ménage, Winter Hawthornden, Striped Beaufin, New Bess Pool, Tower of Glamis, Maltster, Allen's Everlasting, Wormsley Pippin, Egremont Russet, Duke of Devonshire, and Lord Burghley.

There are hundreds of young Pear trees that only produce fruit for perry making that might with advantage be grafted with such varieties as Doyenné du Comice, Louise Bonne de Jersey, Beurre Hardy, Marie Louise d'Uccle, Souvenir du Congrès, Beurre Diel, Beurre d'Amanlis, Clapp's Favourite, Conseiller de la Cour, Gilgil, Catillac, and Verulam. The three last varieties are excellent for stewing, and as that useful class of Pears is becoming more in demand annually, it will pay to bestow more attention to it. In some places that fine late Plum, Pond's Seedling, makes splendid trees, but fails to bear freely. In such cases the heads should be sawn off and Belle

de Louvain put on; some trees worked in that way have never missed cropping profusely for some years. Other excellent Plums for standard trees are Monarch, Grand Duke, Cox's Emperor, Czar, and White Magnum Bonum. Occasional warnings have been given by experienced men as to the danger of having too many Victoria Plums in the country. This is, I think, true, but the varieties named will not clash with that prolific variety, being either a little earlier or later, frequently realising a higher price in the market for that reason.—W. G. C., in *Field*.

## WOODS AND FORESTS.

### WASTE IN TIMBER.

THE subject of waste in timber has been brought forcibly before me during my walks through large areas of woodland in various parts of the country during the summer months. At a time when rents are low, and some even at the vanishing point, it does seem strange that valuable timber is allowed to reach maturity, decay and die, when it might be converted into money. It is useless to advocate the teaching of forestry, to ask for Government grants, to open museums of forestry, and to compare our systems with those of France and Germany when landowners show themselves so indifferent to their own interests.

If farmers allowed their crops to grow and waste upon the ground they would be considered madmen, but year by year trees pass maturity, decay and die all around us without comment.

When large and beautiful Oaks die, which in themselves individually form a feature in the landscape, there is some excuse, for in decay and death there is a grandeur which we are sorry to part with, but this aesthetic view disappears when dealing with trees collectively. I have endeavoured to find a reason for this widespread loss, but have failed to find any but indifference or neglect, for there is no owner, however limited his interest may be in his estate, who may not fell and dispose of ripe timber. If the right does not exist directly, it may be obtained.

I have had occasion often to draw attention to this, and have never failed in carrying my point, to the welfare of the estate both directly and indirectly.

Take one example out of many. On a large estate not a hundred miles from London I have recently seen a Beech wood growing on a slope, the lower fringe upon the chalk outcrop. The trees upon this fringe were high and straight and contained on an average from 40 feet to 50 cubic feet of timber each. Many of these were dead, all not dead were dying, made evident by the yellow foliage in the month of July. In this one wood the loss could not have been less than £300, and the indirect loss arising from the overcrowding of others was also great. I could give numberless similar instances. It should not be forgotten that this direct money loss to the individual is but a trifling part of a national loss arising from a lack of reproduction. A dead tree is valueless, but it occupies as much space as a growing one, and the ground is idle and unproductive. The estate from which I have taken my illustration is an impecunious one, which makes the matter even more extraordinary.

If the teaching of commercial forestry could reach those who own the woodlands of the country, and in whose hands rests the welfare of the country in this respect, many of the financial difficulties under which such owners suffer would pass away. Our woodlands may be made to pay, and large areas now derelict and waste may be planted with a certainty of success, provided, of course, that such planting is done wisely. But it is manifest that this can only be achieved by reaping the produce when ripe.

This waste cannot be denied, because it is one

of those evils which cannot be hidden; therefore, who is to blame, the indifferent owner or the negligent agent?—CHAS. E. CURTIS, in *Times*.

**Prospects of forestry.**—It is a gratifying sign of the times that forestry, and even tree nomenclature, are being taken up by contemporaries whose arboricultural excursions never before extended beyond the "timber" wharves, and whose entire botanical vocabulary was limited to "hardwoods" and "Pine deals and battens." It used to be a standing joke, in fact, that the editor believed that the said deals and battens had an origin similar to that of bricks. This was altered when a real arboricultural society got at him and hauled him off to Scotch woods, where he was undeceived, and for the first time discovered the difference between a Scotch Fir and a Spruce. His own pages will show also that on that particular occasion an enterprising vendor of forest trees got hold of him, took him to his nursery, and persuaded him into the belief that the superiority of his trees consisted in the fact that their growth was matured, not by good culture and a good climate, but by the frequent storms of snow and sleet to which they were exposed. A Scotch paper made fun of this original "vegetable physiology;" but behold, is it not written in "Deals and Battens?" He is now under the tutelage of a recent and enthusiastic convert from Brown, who has got him as far as "A B." When he gets to "D," let us hope that he will cease to display the *Abies Douglasi* as "Douglas Pine" or *Pinus Douglasi*, and bring his lists of "Pines" and "Firs" into some degree of reasonable conformity with his botany.—TIMBER.

## NOTES OF THE WEEK.

***Asclepias curassavica*.**—Some fine sprays of this old stove plant bearing large clusters of red and yellow flowers have come to us from Mr. E. H. Woodall, St. Nicholas House, Scarborough. It is a pretty old plant now rarely seen.

**Plants in Shropshire.**—A note from my district (mid-Shropshire, East), as far as plants and trees are concerned, will perhaps interest others as much as their reports, if located, have interested me. Frost down to zero has injured all our so-called hardy evergreen trees except Box, *Skimmia japonica*, and the delightful *Osmanthus ilicifolius*, all four well exposed, but absolutely unharmed.—R. B.

**Bamboos and the frost.**—"E. M." is to be envied. My experience is very different. The intense frost and keen winds experienced in Berkshire have played havoc with my Bamboos, which hitherto had done fairly well in a partially sheltered border. Metake, perhaps, has not suffered so much as some (*e.g.*, *viridiglaucescens*, *violascens*, *Henonis* and *Scriptoria*). Brown, withered and scorched, they are anything but ornamental plants. Save one or two, they have escaped being killed, and that is all, and I am in doubt whether the canes should be left or cut down, in the hope of fresh canes being thrown up.—F. C., *Erleigh, Reading*.

**A good early pot Melon.**—Early Melons are much appreciated as they come in when there is a lack of choice fruits. I have found these early fruits are often better than those raised under more favourable conditions as to sowing and rapid growth of the plants. I have for some years advised pot culture for early fruits, and one can obtain good flavour with little difficulty when the root space is curtailed. For first cutting in May Ganton Orange is a splendid early variety. This was raised by Mr. Allan, and was given a first-class certificate on May 17, 1892, thus showing its earliness. There is no other variety I have grown more suitable for pot culture. The plant is of robust habit, sets freely, and the quality is all that one may desire. The fruits are deep scarlet, nearly round, slightly netted, and with a clear

golden skin and good depth of flesh for the size of fruits, there being a very small seed space.—G. WYTHES.

**Apple d'Arcy Spice.**—A friend brought us in from the country the other day half-a-dozen d'Arcy Spice from a tree he purchased of us. We think they are rather better specimens than those we sent you, so enclose you two of them. They are somewhat shrivelled from being kept too much exposed to the air, a common fault in storing.—SALTMARSH AND SON.

\* \* Shrivelled, but delicately flavoured and juicy Apples. Probably they would be not nearly so much shrivelled if they were kept in a cool, dark cellar. We think this excellent Apple deserving of much more attention, and we hope that Messrs. Saltmarsh will try it on various stocks, so as to get the most vigorous growth and the highest fertility.—ED.

**Orchids from Abergavenny.**—We have received from Mr. G. C. Williams, The Gardens, Trewyn, Pandy, near Abergavenny, a charming boxful of Orchids, showing that they are well grown in this garden, whilst the flowers represent excellent varieties in not a few instances. *Dendrobium Pierardi* is represented by a fine variety, and also the charming *D. Devonianum*. One of the best forms we have seen of *Odontoglossum Halli* was that of the flower sent, large and unusually rich in colour. *Oncidium Marshallianum*, the brilliantly coloured and large flowered *Mesopididium vulcanium grandiflorum*, a very fine form, *Oncidium Kramerii*, very rich in colour, and *Cypripedium caudatum* were also worthy of mention.

**Strawberry Auguste Nicaise.**—This variety cannot be recommended for flavour, as it is far behind British Queen in this respect, but is equally as good as many others. In these days of severe competition size and appearance are strong points, and a fine dish of Strawberries in April or May is always appreciated. To show the value of the above there is no difficulty when these fruits are sent to market in securing double the price for them. It may be urged that one cannot get the same number of fruits from the plants as with other kinds, but with ample attention to early runners and potting a much greater weight can be obtained if slow forcing and ample food be given, also a cool house when the fruits are ripe. The plants do not winter so well as some kinds and well repay for shelter under glass. In the open they lose all their foliage, and unless the pots are full of roots only finish two or three large fruits. Treated well there is no difficulty in finishing six to ten large fruits.—G. W. S.

**Magnolia Campbelli.**—This lovely Sikkim *Magnolia* is now in full flower for the first time, although it has been planted here for many years and reached the height of 25 feet. It is planted in a nook sheltered from the north and east winds. The flowers, like those of other *Magnolias*, are terminal, the points of all main branches and every side twig being crowned with one large, slightly sweet-scented flower, which is from 6 inches to 8 inches in diameter. The colour of the outside of the flower is dark rose or crimson and lighter inside, with petals of great substance. I attribute its free flowering to the abnormally dry summer here of 1894. I say here because most other parts of the British Isles were suffering from too much rain, whilst all crops here were suffering from the want of it.—W. O., *Fota, Cork*.

\* \* It was a great pleasure for us to see this beautiful flower and real novelty, a large bud and splendid expanded flower, like one of M. Latour-Marliac's great *Nymphaeas*, a beautiful soft rose colour.—ED.

**The Mezereon and its varieties.**—These are very beautiful just now in the Coombe Wood nurseries of Messrs. Veitch and Sons. It is a pity that such hardy and delightful dwarf shrubs are not more grown in gardens, even the common kind being little seen, and then more often in cottage gardens, where in the early spring days its purple-pink flowers fill the air with their sweet odour. A

very fine variety at Coombe Wood is *atro-purpurea*, this being far darker than the ordinary kind, the flowers a rich deep purple, strikingly brought out against the single white l'aphne. This one of the most beautiful shrubs we have. Its leafless shoots at this season are packed closely with large creamy white flowers, which are as fragrant as those of the ordinary kind. A bush of this would give pleasure at this season, especially after such a winter as we have just passed through. Groups of the Mezereon, its white variety in particular, might well be made—not only single plants here and there.

**Spring flowers at Birmingham.**—*Narcissus minor* and *N. minimus*, both easily grown *Daffodils*, are in flower now, a month later than last year. A pan of *Saxifraga Burseriana* showing over one hundred buds and blossoms is a beautiful sight. We grow it fully exposed, and although the pan has been buried in ice, it is not injured in the least. Many of the stems bear two flowers. *Saxifraga oppositifolia* and its white variety are very pretty and easily grown if kept watered in hot weather, and the same may be said of its other varieties. All the Snowdrops have been good, and *Scilla bifolia* improves very much with cultivation and is now much admired. Singularly, the white variety is more robust than the type, and a good patch is very pleasing. *Chionodoxa Lucillie* is very vigorous now; it has been established some years. The flowers vary a good deal in colour and shape.—H. J. SANDS, *Harborne*.

**The weather in West Herts.**—A moderately cold week for the time of year. On no day did the shade temperature at any time rise above 50°, and on the night preceding April 1 the exposed thermometer showed 8° of frost. During the week the temperature of the ground at 1 foot deep has fallen 1°, but only very slightly at the depth of 2 feet. March proved a warm spring month, the mean temperature being higher than in any March during the previous nine years with the exception of 1893 and 1894. Rain or snow fell on seventeen days, to the aggregate depth of rather more than 1½ inches, and was somewhat under the average for the month. With March ended the most important half of the "drainage year" of 1894-5, for after that month very little rain, as a rule, has a chance of descending sufficiently deep into the ground during the next six months to replenish the springs. It is therefore a fact to find that the total rainfall for the winter half of the present "drainage year" was about 1 inch in excess of the mean for that period. In March the duration of sunshine fell short of the average for the month, and was considerably less than in either of the two previous Marches. One striking feature of the past month was the absence of north-easterly winds. Indeed, for only forty-nine hours altogether did the wind come from any point between north and east.—E. M., *Berkhamsted*.

**Cutting Osiers.**—Will any reader kindly tell me how late I may cut Osiers without spoiling the summer's growth? I find it difficult to make purchasers cut them before the end of April, and I think this must cause a diminution of growth in the ensuing summer. The basket-makers like to cut the Osiers late, as they then peel easily, the sap being up.—J. H. W. THOMAS.

**Names of plants.**—*W. H. Cor.*—1, apparently a *Bertolonia*; 2, *Boronia megastigma*.—*F. M.*—*Dendrobium mobile*.

**Royal Horticultural Society.**—The next meeting of the R.H.S. will be held on Tuesday, April 9, in the Drill Hall, James Street, Victoria Street, Westminster. At 3 o'clock a paper on "Campanulas," by Mr. J. Wood, of Kirkstall, will be read.

**The Wild Garden:** or, the Naturalisation and Natural Grouping of Hardy Exotic Plants, with a chapter on the Garden of British Wild Flowers. Fourth edition, with 2000 engraving from drawings by Alfred Parsons, revised and enlarged. Dm 8vo, linen cloth. Price 12s.; well bound in half morocco, 18s. Through all booksellers.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHIDS.

### CHYSIS.

THE few species belonging to this genus are useful free-flowering plants, and as their culture is of the easiest description, provided enough heat is at command, they are essentially amateurs' Orchids. They are strong-growing deciduous epiphytes, and may be grown in suspended pots or baskets. If in the latter, care is necessary to avoid scorching of the foliage by the sun, as although they like a clear light they are easily injured by bright sunshine under glass. The treatment will be similar in many respects to that given *Dendrobiums*, and during the winter more particularly they must be kept well up to the light, or but few flowers will be produced. These occur on short racemes and are developed along with the new growth. The early spring is the proper season to repot, and the compost should consist of equal parts of peat and Sphagnum. The drainage must be exceptionally good, quite two-thirds of the pots being filled and a layer of rough Moss placed over this. *Chysis* like fairly wide pots or baskets, as the roots are plentifully produced. When once they have obtained a hold of the compost they must never be allowed to get dry until the growth is complete. The plants should not be syringed overhead, as the water is very apt to collect in the heart of the young growths, causing them to decay. They are best accommodated in the East India house during the summer, but they should be rested in winter by keeping them drier at the roots and at the cool end of the Cattleya house.

*C. AUREA* comes from Venezuela, and requires less heat than the kinds mentioned below. The pseudo-bulbs are roundish, each about 8 inches in length, and bear light green lanceolate leaves. The flowers are yellow, marked with brownish crimson on the tips of the petals. This is a free-flowering and interesting Orchid, introduced in 1834.

*C. BRACTESCENS* is perhaps the most popular in the genus and deservedly appreciated. It grows rather more strongly than the preceding, otherwise the two are very similar in habit. The racemes bear from four to six large flowers, which, like all in the genus, are fleshy in texture. In the best forms the flowers are each  $2\frac{1}{2}$  inches across, pure white with the exception of the interior of the lip, which is blotched with yellow, and has several brownish crimson lines leading to the column. It was introduced from South America in 1840.

*C. CHELSONI* is a hybrid between *C. bractescens* and *C. levis*, raised by the Messrs. Veitch. The racemes have a more elegant appearance than those of the other kinds, and bear each from four to six flowers, the ground colour yellow, the sepals tipped with purple. The lip is whitish, also plentifully spotted with purple.

*C. LEVIS* is a strong-growing kind which, flowering at midsummer, bears racemes of yellow flowers spotted on the lip with crimson. The plant should be carefully treated while in bloom, and not allowed to remain in a very moist house, or the beautiful flowers will soon be spoiled. A native of Mexico, as also is

*C. LIMMINGHII*, another beautiful kind, and somewhat similar. The flowers are, however, nearly pure white, but tipped with purplish rose. It was introduced about forty years ago, and is among the best in the genus.

*C. UNDULATA* is said to be a native of Guatemala, but as it is extremely rare and apparently never found there by collectors, this statement is not to be relied on. The flowers are bright yellow, produced on long racemes, and the plants grow about 15 inches high. H. R.

### MILTANIA VEXILLARIA.

THE earliest plants of this superb Orchid are now in flower, and where there is a good number of plants they will keep up a fine display until mid-summer. The flowers of this well-known species have a peculiar charm, the simple form and delightful colouring making a change from the singular outline of many other kinds. It is undoubtedly this wondrous diversity of form and colour that has led to the great interest taken in the Orchid family, for probably no other race of plants can equal them in this particular. As a beautiful and free-flowering plant there are few Orchids to compare with *M. vexillaria* when in good condition. To grow it well it requires a good deal of attention in the matter of keeping insects in check, but otherwise its culture is by no means difficult. All practical cultivators will agree that to be successful with this species it must be kept in good health from the first, never allowing it to go back from want of attention either to the compost, to the moisture supply, or in any other particular, but always anticipating its wants. This rule, of course, holds good to some extent with all Orchids, but it is much easier to correct a mistake with many kinds than with the species under notice. Thrips are its greatest enemy, and if once these obtain a firm hold on the plants it is extremely difficult to eradicate them, the young shoots being crippled in the incipient stages and never growing with any freedom. For this reason it is advisable to carefully sponge the plants periodically, whether insects are seen about them or not, using a weak, tepid solution of soft soap. This makes the foliage distasteful to the insects and prevents any possible accumulation of dust or dirt. In the matter of compost, too, never wait until the pseudo-bulbs begin to decrease in size or till the peat has become a soddened, close mass before repotting, but give new compost as soon as the roots have become well matted in the pots, biennially or even annually if necessary. The best fibrous peat with all sand and earthy particles shaken out and clean, fresh Sphagnum Moss should be used, with a little charcoal or crocks broken to various sizes according to that of the pots used. These must be clean, drained about two-thirds of their depth, taking care to have a large piece over the hole with the convex side upwards, and smaller pieces near the top. A little rough Moss must be laid over this before placing the plant in position, with the leads well above the rim. Disturb the roots as little as possible, but avoid leaving anything behind likely to cause sourness. In bedding the compost arrange it so that the bases of the leading pseudo-bulbs are hardly buried, the new growths just resting upon the surface. I do not care to repot this Orchid in spring, a more suitable time being about September or just as the growth is well on the move, keeping the plants rather closer afterwards in order to avoid any check. It is not fastidious as to temperature, some growers succeeding with it in the cool house. The best place for it is, I believe, on the side stage of the Cattleya house close to a ventilator, as a free circulation of air is very desirable. In this direction, however, circumstances greatly alter cases, so that if growers are not successful with the plants in one place they should give them a trial in another, and when a suitable position has been found leave them there, attending carefully to their wants in other respects and at flowering time they will not regret the trouble taken. Experienced growers are in the habit of supplying weak liquid manure to this species when finishing its pseudo-bulbs, and the magnificent racemes of flower produced under these conditions are a convincing argument in favour of the practice. It must not be forgotten, however, that in other than experienced

hands this is dangerous and much better left alone altogether than overdone in the least, so that while not deprecating the use of stimulants I would advise amateurs and beginners to experiment with them at first on grosser growing Orchids.

*M. vexillaria* requires a good supply of moisture all through the season, varying it according to the weather and the state of growth, and during spring and summer the plants may frequently be dewed overhead with tepid water from the syringe, excepting of course after the blossoms show colour. There are many named varieties of this Orchid, the colour ranging from nearly pure white through varying tints of rose and purple. A typical flower would measure about 3 inches across the labellum, and this, in addition to the sepals and petals, is rosy pink with a few streaks of yellow leading to the column. *M. vexillaria* was described as an *Odontoglossum* by Professor Reichenbach, and is a native of New Grenada.

### THUNIAS.

THE season for repotting these charming Orchids having again arrived suggests a note on their culture. They are all free-growing and constant flowering Orchids of a deciduous habit of growth, blooming on terminal racemes from the apex of the pseudo-bulbs before the leaves fall. They are naturally epiphytes, but thrive under cultivation in a more substantial compost than most Orchids. Good fibrous loam and peat in equal proportions with a liberal admixture of chopped Sphagnum and very fine crocks will suit them well, a few nodules of charcoal about the size of horse beans being also serviceable in keeping the soil open. They should be grown in pots, which must be clean and filled to half their depth with drainage, covering this with the rougher parts of the compost. Pull the plants quite out of the old soil and shake it all away from about the roots, as they are strong feeders and usually exhaust the soil during the first season. A few of the old roots may be left to steady the plants a little, but they are of no further use, and most of them should be cut away. From three to six stems may be placed in each pot according to the size, which may range between 5 inches and 9 inches or even larger. The surface of the compost should be kept rather below the rims of the pots as in the ordinary way, the base of the pseudo-bulbs just resting on this. A small stake may be put to each to steady it until roots are produced. After potting place in the East India house and keep quite dry until roots are being emitted, when a little water will be required, increasing this as they run in the compost. When growing freely a plentiful supply will be needed, and when the pots are filled with roots, a little well-diluted soot water or other liquid manure may be given, but be sure the plants are moist at the roots before this is applied. *Thunias* delight in a hot and moist temperature with plenty of sunlight while making their growth, but after flowering they should be gradually dried off, no water being required in the depth of winter. They may be easily propagated as described recently in THE GARDEN by cutting the pseudo-bulbs into lengths as soon as they attain to maturity.

*T. ALBA* grows about 2 feet high and produces about a dozen flowers upon a semi-pendulous raceme. These have the sepals and petals pure white, the lip also white with faint purple markings. Introduced from India about 1840.

*T. BENSONI* is similar to the last-named in habit, but the flowers are magenta-purple with a yellow crest on the lip. This is a native of Moulmein, introduced in 1867.

*T. CANDIDISSIMA* comes from Burmah, and was introduced with an importation of *Dendrobiums*, first flowering with Sir Trevor Lawrence. This is similar in growth to *T. Marshalliana*, and the flowers are wholly pure white.

*T. MARSHALLIANA*.—This magnificent kind is more popular than any, and deservedly so, as no Orchid is more easily grown or bears more beautiful flowers. These are large, magenta with the

exception of an orange and yellow crest to the lip, which is exquisitely fringed at the edge. Several varieties of this species are in existence, including *ionophlebia*, *purpurata*, and *triloba*, these differing from the type chiefly in the disposition and tints of colour on the lip.

*T. VEITCHIANA* is a hybrid between *T. Marshalliana* and *T. Bensonii*, first exhibited in 1885. The flowers are white, the tips of the sepals and petals shaded with mauve. The lip is white with mauve and purple markings. R.

## KITCHEN GARDEN.

### PRACTICES IN POTATO CULTURE.

Customs that have long been established are not easily upset. Especially is this the case where the working classes in rural districts are concerned, these proving the most conservative of all. You may meet them in fair argument and ridicule their notions to your heart's content, only to feel that they will go away as firmly convinced as ever that they are right and you are wrong. At least, such is my experience, and I find there are many more similarly situated. Meetings of working men are more interested in Potato growing than any other subject that can be brought before them, and, curiously enough, what they appear to most need—viz., abundance of Potatoes—they make the most mistakes in producing. My contention is the working classes are not generally successful Potato growers, very few, comparatively, lifting anything like such heavy crops as they ought to do under spade cultivation. It is in the matter of planting tubers or sets that most mistakes occur. Too often next to nothing is thought about these till the heap stored in the previous autumn has been used from for a long time and very freely, scarcely enough being left to meet the exigencies of the situation. Not only does this usually mean a loss of vitality owing to premature sprouting, but it also necessarily entails much cutting up of tubers in order to have sufficient for planting. To the average cottager it seems sheer waste to plant whole tubers. When I tell them nothing under a 4-oz. set should be cut, and that a 3-oz. tuber is the smallest that ought to be planted, the assertion is made, and which is only too true, that the latter are frequently cut into three pieces and duly planted. The growth from such puny sets must of necessity be very weak, and who ever yet obtained a heavy crop of medium sized to large tubers from feeble haulm and stems? It has been proved beyond contradiction that the growth resulting from well-kept 3-oz. and rather heavier whole sets invariably gives the best results, and it is this size of tuber that ought always to be selected at lifting time, stored separately and thinly where they can be protected from severe frosts, and at other times exposed freely to light and cool air. It is only fair to add that very many gardeners are equally indifferent as to the preparation of their planting tubers, not bestirring themselves about them till it is too late. In some parts of Somerset the curious notion prevails that not only ought all Potato sets to be cut, but that also the cut sides should be placed uppermost in the drills. It is thought by some that the Potatoes do not bleed so much when the cut side is uppermost—at least they offer that as an excuse for the practice, but still more claim for the plan that it leads to the sprouts coming from underneath in a curve gaining a stronger foothold in the soil accordingly. I was under the impression that a strong sprout growing straight upwards gave by far the best results, but when whole villages follow such a time-honoured custom of planting cut side uppermost, what I have had to say about it will not influence them much.

It is also worthy of note how tenaciously cottagers cling to the practice of planting Potatoes thickly. In some districts the rows of all but the short-topped early varieties, or Ashleafs prin-

cially, are disposed 20 inches apart; in other places 22 inches are allowed, the distance apart in the drills varying from 8 inches to 10 inches apart. My advice has been very frequently given to the effect that it would pay them far better to be less free with their knives and to allow a medium-sized tuber the space usually given to three small cut sets, and to note the results. It is quite a waste of time to talk about planting in drills 3 feet apart unless the proposal is made to plant Brussels Sprouts or other winter crops between, but rows 30 inches apart and 12 inches between the sets do not scare some of them, and it may be this will prove a step in the right direction. As a matter of fact it is enough on ground frequently producing the same crops and not often manured. All those who have any difficulty in convincing working men that they overcrowd their rows ought to ask this question: Where are the best hills or single plants of Potatoes invariably to be found at lifting time? It is never disputed that these are at the ends of the rows or where the most light reaches the plants and air and warmth reach the roots, and when once men are set thinking in that direction the more intelligent of them begin to see "something in it." Having the whole of the ground heavily covered with haulm may seem encouraging or to presage a heavy crop, but this is too often overdone in gardens under the charge of professional gardeners as well as in cottagers' gardens, those responsible overlooking the fact that plants more thinly grown produce much the best crops of tubers, and this whether as regards weight, appearance, or quality.

As an extra inducement to owners of small gardens to allow more room for their Potatoes than heretofore, I usually advise them to resort to the very old practice of sowing a few Broad Beans very thinly along the rows as the planting is proceeding; not, however, to the extent of growing as many stalks of Beans as Potatoes, as this would mean the production of far more pods than are needed and the shading and weakening of the Potatoes. A Bean seed dropped in after every third Potato set is ample, and these duly moulded up with the Potato haulm will crop most abundantly and not interfere with the more important crop in the least. Out of this practice has grown another, and which also answers well. With the rows of erect sturdy-growing Potatoes, notably *Magnum Bonum* and the variety very hard to separate from the latter, and known as the *Bruce*, not less than 30 inches apart and the sets 12 inches apart in the rows, Peas may be grown in the rows with very surprising results. In this case a single plant is allowed to attach itself to each Potato plant, and this it does, cropping most satisfactorily, too, without any apparent detriment to the weight and quality of Potatoes eventually lifted. Naturally it is the medium height varieties that should be preferred for this method of double cropping, and if more seeds are sown than plants are needed, then the surplus has to be drawn out in due course. Arranging the rows of short-topped, early-maturing varieties not less than 3 feet apart, and after these are moulded up planting Brussels Sprouts, *Borecole*, autumn Broccoli, and autumn Cauliflowers between, is not largely practised in small gardens, the owners of the latter preferring rather to crop more closely with Potatoes and to plant the same classes of winter crops in succession to these. This is a decided mistake. They may obtain more Potatoes by closer cropping, but instead of the ground being waiting for the plants of other vegetables named, the plants are invariably waiting for the ground, and as a consequence are greatly hindered thereby, never really recovering from the check. It is the Ashleaf varieties, notably the old *Myatt's*, that I would still grow the most extensively with a view to intercropping; but if somewhat later maturing varieties are similarly planted, the lifting should take place directly the tubers are full sized, not waiting for the haulm to actually die down. In this way disease is often escaped and the lifting is done while yet this is possible without damaging the Brussels Sprouts

and such like. Soil previously drawn up to the Potatoes ought to be worked with a spade up to the stems of the other plants that are soon to cover the ground. If it is scarcely possible to grow too many Potatoes, then I would advise marking out intended sites for runner Beans and late Peas, cropping the spaces between with two or three rows of second early Potatoes. The latter may also be grown to within 2 feet or even less of intended rows of Vegetable Marrows and always in advance of the main crop of Leeks. Early Potatoes should precede Strawberries—are a good preparation for the latter, in fact. A ROVER.

### EARLY FRENCH BEANS.

All have not the convenience to force this vegetable in pots in forcing pits or hot houses, but others may secure an early supply by sowing in  $4\frac{1}{2}$ -inch pots in frames and then planting out on a warm border and protecting at night. For years I have adopted the plan advised, and there is no crop more profitable than these early dwarf Beans when a little trouble is taken in raising an early crop. Requiring early vegetables in quantity, a few years ago I tried every kind of Bean I could obtain, and sowed two rows of each on an early south border to test earliness, as a few days with this crop is of great importance, and out of at least a dozen kinds, *Mohawk*—or, as it is well named by some, *Six Weeks*—came in fit for table in advance of all others, so that I advise it for sowing in pots to plant out for first crop in the open. *Mohawk* possesses other advantages: it is very dwarf, with good habit, and a very free cropper, producing a nice sized pod and of good quality. I have by careful selection of the first podding plants got a very early variety, certainly larger in pod and with more top, but a good form for planting out of pots, as earliness is a gain in the right direction. Many may be able to sow a few dozen pots for planting out, and these sown now will come in in advance of those sown in the open by several weeks. The seed may be sown in any warm place, and when a few inches above the soil removed to cold frames, watering sparingly, planting out, after being hardened off in the open, at the end of April or early in May. At that date protection will be necessary, and it is well to plant on a warm border in front of a fruit house. Such plants can readily be protected by hand-glasses, mats, or other coverings, and will well repay for room occupied. If raised as advised and grown in cold frames the plants soon take to the soil, but there is no gain by raising in strong heat and allowing the plants to draw or fall over the sides of the pots. There should not be any check from the start, and there is no fear of collapse if the plants are not forced too hard. When planting, I find deep drills a great saving, as these shelter from cold winds, and it is a much better means of watering in dry weather. When planting it is advisable to make the plants firm. Shelter for a short time and give tepid water to settle the soil round the roots. G. WYTHES.

**Kales and the frost.**—Such seasons as we have just passed through will prove the value of the hardier varieties of Kales, as these are now just breaking away freely and will give a lot of useful greens. The Arctic Kales I noted the value of in an earlier note, and my remarks now more concern the old form of Cottager's and Asparagus or Buda Kales. Even the last-named varieties are hard hit, the tops or heads being crippled where the plants are tall or were raised early. Plants raised from seed sown early in May, specially for late greens, are little injured, and though small, will be invaluable for spring cutting, and as spring Cabbage will be late this year, those who have late Kales will find them more valuable than ever. By lifting a few and planting on a north border the plants will get a check and not run to flower so quickly. The other varieties, such as the *Chou de Russe*, *Ragged Jack*, and *Dwarf Curled Scotch*, are good. A portion of the head is injured, but the stems are sound and will furnish a lot of young shoots.—S. H. B.

## FLOWER GARDEN.

## SHIRLEY POPPIES.

THE conventional floral arrangements one generally sees, although composed most gracefully, bear the stamp of laboured production too plainly, and lack the simple expressive charm so characteristic of such arrangements as that here illustrated, in which the flowers show all their natural grace and form free from all trace of design. The essential thing always is to have vases or receptacles suitable in shape for the flowers that are to be placed in them, and beyond a pleasing foil of pretty leaves or grasses it is much the best to let flowers that can be gathered in plenty make their own picture in the house as they do in the garden. Of the many types of Poppies now grown few are of any use to cut for the house, but the Shirley Poppies are delightful and a noteworthy exception. Their long-stemmed flowers in lovely

found them to vary greatly both in foliage and flowers. On some plants the pitchers are rather long and narrow and quite devoid of coloured markings, while others are found with much shorter and broader pitchers and with markings varying from a mere dotting with chocolate colour to an entire covering of the leaf with reddish chocolate, it being also noticeable that those having the darkest foliage have the finest and most brightly-coloured flowers. It is also worthy of note that those plants that were protected to some extent from the winter sun by the dead grass and fallen leaves passed through the cold weather in much better condition than those that were fully exposed.

Under very similar conditions to those in which we find the *Sarracenia*s, that is, nestling among Sphagnum in decidedly boggy localities, we also find two or three very pretty little Sundews, *Drosera rotundifolia* being the most common species, while *D. longifolia* and *D. filiformis* are not so readily found, and are consequently of more interest to the collector. Among the many interesting bog plants found in some portions of New Jersey and adjoining States are also two particularly charming little Orchids, namely

tide-water. In such localities it appears in great masses from 4 feet to 6 feet high and bearing quantities of flowers that are frequently 6 inches in diameter.

Numerous variations of this species are found, the type having light rose-coloured flowers, while pure white is not uncommon, and a particularly handsome form is that having white flowers with a deep crimson eye. As this *Hibiscus* seeds very freely it becomes quite an easy matter to propagate these particular forms, some of which have thus been sent out as novelties by enterprising seedsmen.

W. H. TAPLIN.

*Philadelphia, Penn.*

## AN EXHIBITION OF LILIES.

WHILE agreeing generally with the opening remarks of "H. P." at page 107 on the above subject, I think that his concluding remark savours too much of despair. At no season of the year, it is true, would it be possible to produce anything like a representative display of Lilies, yet it is surprising what can be done by specialists when sufficient notice has been furnished of the date of exhibition, and with the additional advantage of northern as well as southern growers contributing. A much larger display of these flowers could be brought together in the early part of July than at the same date in August. It would, perhaps, exclude the *speciosum* and *auratum* sections, but it is quite possible that such an exhibition would be more generally useful and instructive without these groups, because they are more generally known and cultivated among amateurs than the majority. By forwarding in some instances and retarding in others a considerable number which could hardly be had in good condition a month later may be brought together in July. An exhibition in July should include *L. candidum* and its varieties, the well-known *L. Harrisii*, as well as the *longiflorum* of the Dutch growers; also *longiflorum* of Japan, which contains many of the variety *eximium* as well as other distinct forms. It would be quite easy to have these latter good for July or August by utilising the importations now coming to hand. By potting the dry bulbs at once and plunging them behind a north wall in cocoa-nut fibre they could be kept back considerably. The same remark applies to any dry bulbs of *clavatum* and others which flower near the time stated. Established pots of *speciosum album* and *Kraetzerei* could be had by July if placed at once in a greenhouse temperature, also the earliest importations of *auratum* if now well rooted and similarly treated. The Tiger Lilies may possibly require forwarding slightly, though not in the early stages, while *chalcidoneum* may need keeping back a little, unless the Scotch growers of this kind are later than the English growers. *L. Browni* would almost certainly be in good condition, as also some of the Martagons. Indeed, it would be difficult to speculate with any degree of certainty on what kinds may be brought together from all quarters. Scotland, for example, could supply species and forms of those earlier kinds which in Southern England may have long since passed out of bloom; while the Isle of Wight and Devon, to say nothing of growers in the Channel Islands, may send out specimens of many things as yet only in bud in other parts. Apart from the interest attaching to the exhibition itself, a series of practical papers would prove of great help to a very large number who now cultivate these beautiful plants, while a comparison of the varied experiences of growers in different localities would assuredly be of interest to many.

E. J.

*Spiræa astilboides floribunda*. — This, which was alluded to on p. 227 as one of the best of herbaceous *Spiræa*s, has made a considerable advance in favour within the last two or three years. Last season it received an award of merit from the floral committee of the Royal Horticultural Society on June 26, a large basket full of

A bowl of Shirley Poppies. From a photograph sent by Mr. J. Nash, Chapel Street, Berkhamsted.

shades of soft colour offer a fine variety and are free from objectionable odour. The flowers last longest when cut in the bud state, the buds opening perfectly in water. These Poppies are very handsome in the garden when well treated, but, in common with most annuals, they suffer from overcrowding. With abundant room to grow, the plants become nearly a yard in height and diameter, perfect bushes of profuse bloom.

## SOME AMERICAN HARDY PLANTS.

WHEN reading Mr. J. Wood's very interesting "Notes on Hardy Plants" in THE GARDEN of February 16 it seemed somewhat odd to find the hardiness of *Sarracenia purpurea* questioned, but as there doubtless are great differences in the climatic conditions of Yorkshire and the Eastern United States—even though the temperature of the latter may be lower during the winter—one can readily understand that such difficulties may arise in the establishing of this plant. I also agree with Mr. Wood that there are several varieties of *Sarracenia purpurea*, for I have examined a large number of plants growing wild in the swamps of New Jersey—where a temperature of zero is not extraordinary in the winter season—and have

*Arethusa bulbosa* and *Pogonia ophioglossoides*. The former is rather scarce, but pretty enough to be worthy of a hunt, its usually solitary flower of bright rose-purple being very attractive.

*Pogonia ophioglossoides* can sometimes be gathered freely, its sweetly scented flowers of rose colour, or sometimes nearly white, being about 1 inch in length, and there are frequently three or four flowers on a spike.

Still another hardy Orchid, of some value as a foliage plant, is the Rattlesnake Plantain or *Goodyera pubescens*, the white reticulated foliage of which is found in rather damp woods and usually in well-shaded spots. This is really a very pretty species, and I can well remember with what enthusiasm I carried home my first specimen of *G. pubescens*. I was a boy of about twelve years at the time, and having previously seen some *Anacochili* I felt convinced that I had discovered a new species of that family. My ideas were, however, soon corrected on that point, but I have always had a tender feeling for the plant since.

One of our most attractive hardy perennials during the middle and latter part of the summer is the Rose Mallow (*Hibiscus moscheutos*), which is usually found in perfection near the seashore or on the edges of brackish swamps adjacent to

fine plants being then shown. It is of Belgian origin, and is said to have originated as a seedling from a plant of *S. astilboides*. The flower panicles of the newer form are longer and more branched, whilst the individual blooms are whiter than those of the type. It seems to be even more amenable to forcing than *S. astilboides*, but not so readily as the common *S. japonica*.—H. P.

**Iris reticulata and Dog's-tooth Violets.**—Spring flowers this year are so late, and in consequence so doubly welcome, that perhaps one exaggerates their charm. Certainly they have never seemed better or brighter in my eyes. One group in particular on the spring rockwork is so much admired, that in case the combination is new to others, as it was to me, who has not been in England at this season for years, I put it down on paper for your benefit. Three years ago a good clump of *Iris reticulata* was planted in sandy loam and left to itself. The ground has become slightly covered with trailing plants, and some Dog's-tooth Violets, that no doubt had been there before, have made a perfect carpet of soft pink flowers and bronzy mottled leaves under the luxuriant mass of *Iris* blooms and spear-pointed leaves. The "shot silk" effect of the purple and gold on a pink and brown ground is one of the prettiest things I have ever seen, and in large quantities would be the loveliest effect possible. Spring *Leucocjums* and *Scilla bifolia* are pretty together, but for a combination I know nothing that can surpass *Iris reticulata* and Dog's-tooth Violets.—E. H. WOODALL, *Scarborough*.

#### NOVELTIES EXHIBITED AT THE HAARLEM FIFTH QUINQUENNIAL BULB SHOW.

SOME fine novelties among bulbs were exhibited at this show, which was held at Haarlem, the centre of the Dutch bulb-growing district. Among *Hyalanthus*, which were shown in considerable numbers, the following were conspicuous: *Isabella*, double, blush-white, deeper towards the centre, an immense and very closely-set spike, by far the largest among the double varieties; *La Grandesse*, double, white, a sport from the well known single pure white variety; *Kastanjeblom* (chestnut flower), a large spike of pyramidal form, the bells very large and of a pale flesh colour. In single varieties the following are distinct gains: *Dr. Windthorst*, blush-white, very large and long spike; *Potgieter*, pale blue, very large; *Cardinal Wiseman*, pale carmine-rose, with darker stripes; *Jacques*, immense spike, pale rose; *City of Haarlem*, fine yellow, large spike, closely set.

Tulips were shown in considerable numbers and of excellent quality. There were very few novelties, but the following comprise a selection of the best: *Emperor Alexander*, very double, bright red and yellow, showy; *Toreador*, double, deep red and orange, fine; *Prince of Orange*, deep orange, a glowing colour; this is a sport from the lilac-coloured variety *Violet Fonce*, and is a splendid kind; *Jeanne d'Arc*, white, pale rosy tinge, large and fine flower; *Lord Rosebery*, pale rose colour, fine flower; *Golden King*, pure golden yellow, a sport from the old variety *Tournefol*, and the best double yellow Tulip in cultivation; *La Parfaite*, bright red, yellow edged. These are all double varieties. One the best single varieties exhibited was *Queen of the Netherlands*, which has a very large, nicely shaped flower of a pale rose colour. *Visser* has a bold flower of a dark brown-red. *Kuypp*, white and red, and *Etoile Brillante*, bright scarlet, were good.

There were three groups of Tulip species shown, which proved a great attraction. *Tulipa Kaufmanniana* is a very early and showy Tulip, in bud much resembling some of the *Magnolias*, the body colour being white, yellowish towards the centre, and with a dash of red on the outside of the flower. *T. violacea*, a charming new Tulip, with bright magenta-red flowers, very early; *T. limifolia*, narrow leaved, bright scarlet flowers; *T. Batalini*, pure soft yellow, a small but pretty

flower, are all good early-flowering species. *Iris*es were shown in great variety by M. Van Tubergen, of Haarlem. There were not only all the early-flowering varieties, comprising such gems as *I. histrioides*, *I. Danfordia*, *I. reticulata* in variety, *I. Rosenbachiana* and *I. persica*, but in addition to these there were well-flowered examples of the *Korolkowi* group, *I. Kochi*, fine purple, many varieties of *I. hispanica*, and the choice *I. Boisierii*.

From the same exhibitor came a nice group of new *Lachenalias*, which received the first prize as the best new bulbous plants recently introduced into commerce. This group included the varieties *Cawston Gem*, a giant among *Lachenalias*, foliage broad and massive, the flower-spikes very long, and the bells large; *L. Ruby*, a very free-flowering, bright coloured form, which perhaps might be best described as an improved tricolor; and *L. Topaz*, pure waxy yellow, very fine. These were all figured in THE GARDEN for September 29, 1894. A second prize went to Messrs. Krelage and Son, of Haarlem, for *Arum Eggeri*, a plant somewhat in the style of *A. palestinum* (*sanctum*), but the spathe, instead of being of a uniform deep brown-red, is of a lighter shade and spotted. A very fine group of fifty pots of miscellaneous bulbous plants included a nicely flowered example of the white form of *Gladiolus byzantinus*, *Habranthus pratensis*, brilliant scarlet; *Camassia esculenta major*, a fine form of this well-known plant; *Scilla sibirica alba*, pure white, a promising novelty; *Anemone fulgens Leichtlini*, large flowers, with a white centre; and *Iris histrioides*, a brilliant pale blue, one of the best early *Iris*es. A VISITOR.

#### FLOWER GARDEN NOTES.

**DAFFODILS.**—When in 1894 we started cutting *Tenbys* in quantity by the end of January, being helped thereto by a good mulching of leaves through which the frost did not penetrate, and having no very cold weather to check the progress of foliage and flower-stems, it seemed as though the culture of Daffodils in pots was hardly necessary, but this opinion has to be considerably modified after the experience of the present year, when from the very same clumps the first flower was not open until March 23, and all anticipations of an early supply of outdoor blooms have ended in disappointment. It is not, I think, generally known as yet that for pot work Daffodils in variety yield for a comparatively small outlay a better and more enduring display than can be obtained from any other bulb, the lengthy season being naturally due to a careful selection of varieties. The choicer kinds cannot, of course, be included in such selections if the expenditure is limited; these, however, are not essential if a good blaze of colour and something to fill the vases are the principal consideration, and of the kinds enumerated under "good for forcing," bulbs are obtainable at from 5s. 6d. to 10s. 6d. per 1000. The kinds I have grown are two sorts of *Bulbocodium*, *obvallaris*, *Golden Spur*, *pallidus precox* and *princeps* in the trumpets, *Leedsii*, *Magog*, *Cynosure*, and *Stella* in the star section, *triandrus albus* and the single and double forms of *poeticus*. Two parts of friable loam to one of leaf-soil is a good potting mixture, a fairly good and holding compost being conducive to the production of stout, stocky foliage and fine flowers. The number of bulbs to be placed in pot or pan will, of course, depend on their individual size. It is advisable to have ready some nice fresh Moss and to cover the surface of pot or pan so soon as growth commences, so that the young foliage can push its way through the same. Where there is a demand for flowers for church decoration it is always advisable to have plenty of Daffodils for Easter; they are used largely in many places, and very pleasing arrangements can be made with them if they are put up with their own foliage in a light, natural manner. I have been led to the subject of forced Daffodils in these flower garden notes from the fact that the same bulbs having served one purpose may afterwards find a home on the borders of lawns,

in shrubberies or in the wild garden. Turned out of pots and planted for the time being in some odd corner, taking care, by the way, to label them correctly, that there is no confused mixture at planting time, they may, as the foliage on such bulbs naturally dies away quickly, be consigned to permanent quarters any time during the summer when convenient.

**POLYANTHUSES.**—With the advent of better weather flower buds are pushing up fast, and a very fair display will soon be obtained. A sharp look-out must be kept for sparrows, these mischievous rascals being sometimes answerable for the destruction of a lot of flower buds, especially if the weather is cold and bleak and succulent food is scarce. Black cotton will keep them away if placed at a slight distance above the plants, the rows or interlacing of cotton being fairly close together, so that the birds are baffled if they attempt to alight. If fish netting is available, this, with the aid of a few benders, may be placed over the beds until a fair amount of buds is on the point of expansion. On dry porous soils where beds of this favourite spring flower are fully exposed to the sun they should be well mulched with short manure. Unprotected beds in a hot dry spring are not likely to give a good display of flower. Specially good flowers may be marked for seed-saving if a fresh stock is required, and if sowing is contemplated this spring, April is a good time to get in the seed. I find a south-west or west border, the latter preferably, the best for the purpose on our light dry soil, and if the weather shows signs of a spell of drought it is a good plan to damp the drills before sowing and to shade slightly in the middle of the day until the seed has germinated. An essential feature towards securing a quick return of good plants is to transplant directly the seedlings can be handled to prevent the formation of a tap root of abnormal length. Failing the prospect of doing this at the right moment—that is, if the seedlings are to remain some time in the seed bed—the latter should be made very firm and solid before the seed is sown.

**COMMON FLOWERS.**—The fact that all outdoor flowers that beautify the garden in late winter and early spring are necessarily of the hardiest type is sufficient to create possibly a greater liking for them at this season. They have not, like herbaceous and bulbous plants, later on to chance comparison with tender subjects, but are emphatically alone in their glory. I was much interested the other day in a chance contrast that will be bad to beat all through the season. A batch of *Sedum Lydium* had to come away from a certain portion of the garden last autumn and occasional clumps were made in the front of herbaceous borders. I did not remember at the time that the same ground was always occupied by *Crocus*. Such, however, was the case, and the bulbs, mostly in the dark and light blue shades, pushed up through the carpet of *Stonecrop*, and the bright colour on the intense green of the *Sedum* was a very pleasing sight. *Hepaticas* are beautiful just at present, a thoroughly good early old English flower that is not half enough grown. They are not at home in all situations, and are never likely to be satisfactory if planted right out in the open border, especially if that border is much exposed and the soil is a bit dry and light. The best lot of *Hepaticas* I remember to have seen was growing on a low rockery that had been tastefully made on a narrow stretch of lawn in a sheltered spot not far from a running stream. The soil, naturally a good loam, had been deeply dug and well prepared. The old double red and double blue varieties make charming button-hole flowers, anything in this way being at times a relief from the more elaborate arrangements obtained from stove and greenhouse. Given a favourable time, we shall soon welcome the first flowers of the alpine *Phloxes*, and the green carpet will quickly be changed into sheets of white, mauve, pink, rose, and lilac. There is a strange difference in the requirements of these *Phloxes* and the *Hepaticas*, for whereas the latter, as mentioned above, like a sheltered, moist, and shady spot and need a bit of good soil,

the Phloxes will be seen quite at their best on dry, poor borders, banks, or slopes. Another early-flowering plant that adapts itself readily to similar situations is the perennial Candytuft; indeed, this seems to flower with the greatest profusion on poor borders.

NATURALISATION OF HARDY FLOWERS.—It may not be out of place to refer thus early in the season to this subject, and to suggest the advisability of keeping a sharp watch on all the different species with which experiments have been made with the view to ascertain, both from their habit of growth and from the profusion or scantiness with which flower is produced, whether they are in congenial quarters and are likely to be a permanent success. This latter is essential in

of varieties of similar species with which one has to deal.

E. BURDELL.

Claremont.

TREES AND SHRUBS.

THE VINES.

(VITIS.)

THERE is, perhaps, no feature in the adornment of our gardens and woodlands where the gardener's art can be more effectively displayed than in the use of climbing shrubs. There is a peculiar charm about these plants which no

to a less degree only in Asia Minor. Except in the case of the Hop-leaved Vine hereafter mentioned, it is not for the beauty of the fruit that the wild types of *Vitis* are grown in these islands. It is their luxuriant habit, surpassing grace, and wealth of handsome foliage, which in several instances affords the richest of autumnal colours—yellows, purples, and crimsons—that constitute their great value.

Some thirty species are at present in cultivation that can be grown out of doors in the southern parts of this country, a very small proportion, of course, of the total number of species known, most of which are semi or purely tropical. They are all of climbing or rambling habit, and their variety in foliage and different degrees of vigour in growth enable one or other of them to be employed for almost every purpose to which climbers may be put. Whilst some are especially valuable for the walls of houses, others may be used for covering arbours, pergolas, the pillars of verandahs, old tree stumps, or sloping banks. In the case of the stronger, taller-growing species they may be made to clamber over living trees. Little need be said on the matter of cultivation. They are moisture-loving plants, and require liberal treatment at the root. Where space is limited they can be kept at any required size by means of pruning, but the most luxuriant effects are, of course, obtained where they can ramble without let or hindrance. Where they are intended to spread over living trees, they should always be planted sufficiently far away from the trunk to allow rain and light to reach them. Success, too, will be better assured by giving them a pocket of good rich soil to start in. In the majority of the species increase can be accomplished by means of cuttings or by single "eyes," treated like those of the common Grape Vine. Some, however, are very obdurate and can only be increased by means of seeds. Layering will occasionally prove successful with those that refuse to root from cuttings. Grafting should only be resorted to as a last resource.

In the following enumeration of species the nomenclature adopted is that of the recently published "List of Hardy Trees and Shrubs" at Kew. The generic titles of *Ampelopsis* and *Cissus* are therefore sunk under *Vitis*.

AMERICAN SPECIES.

*V. ESTIVALIS* (Summer Grape).—This species is probably the oldest of North American Grape Vines cultivated in England, having been introduced in 1656. It is described as abounding in wastes and woodlands. The leaves are broadly cordate, more or less deeply three to five-lobed

Wild Grape Vines in the Upper San Joaquin Valley, California.

naturalisation. Puny, sickly growth, with here and there a flower, is just as much a failure as from a purely natural standpoint is the indiscriminate grouping of varieties of any particular species that may vary greatly in many features. The natural requirements of plants must be the first consideration, and there is no doubt that many failures in naturalisation may be traced to the lack of careful observance of such primary rules, resulting not only in a loss of time and labour, but in a display that is mean and poor instead of bright and natural. True guides as to where to plant are obtainable not only in the writings of those who have been successful, but often in the careful study of the habitat and surroundings of the inmates of our fields, hedges and woodlands, and a deduction from this as to the requirements

other class possesses to the same degree. It is due to their surpassing grace, and to some extent also, no doubt, to the strong suggestion they give of the luxuriance that more especially belongs to the vegetation of warmer, sunnier lands than ours. Our indebtedness is shown in this, as in every other branch of ornamental gardening, to the floras of other countries, and in the beautiful genus with which in this paper I have to deal there is not a single species that is a native of Great Britain or even of Europe. The Grape Vines and the *Ampelopsis* (now included under *Vitis*) are, in regard to hardy species, represented most strongly in North America and Northern Asia,

being of a deep green colour when old, but in a young state covered on the lower surface with a reddish down. They measure from 4 inches to 6 inches across, the marginal teeth being broad and shallow. The berries are small—about the size of Black Currants—but have been improved by cultivation. The larger-leaved forms of this variable species are sometimes mistaken for *V. Labrusca*, but a ready distinction is afforded in the arrangement of the tendrils. In *V.estivalis* the tendril is missing from every third joint, but in *V. Labrusca* there is (with rare exceptions) a tendril or fruit-stalk at every joint.

*V. CALIFORNICA*.—This is, so far as my experience goes, the best of the American Grape Vines (*i.e.*, excluding the *Ampelopsis*) for colouring in autumn. It is one of the strongest growers, climbing in its native home over lofty trees. Its leaves, which turn a deep crimson in autumn, especially after a summer like that of 1893, are rounded and covered with down.

*V. CORDIFOLIA* (Frost or Winter Grape).—A strong, vigorous-growing plant with thin, three-lobed, cordate leaves, measuring 3 inches to 6 inches in diameter, the lobes ending in a long, fine point, the coarse teeth being also sharply pointed. The berries are black and only palatable after they have been subjected to frost, hence the common name of Frost Grape. A moisture-loving Vine, affecting in a wild state the banks of streams. It has the same arrangement of the tendrils alluded to in *V.estivalis*.

*V. RIFARIA* is a near ally to the preceding, and by some authorities is reduced to a variety of it. The leaves are larger than those of *V. cordifolia* (although the plant itself is smaller), smooth and shining, with long pointed teeth. The sweet, Mignonette-like perfume of the flowers of many American Vines is in this species especially apparent. The variety *palmata* (*V. palmata*, Vahl.) has the branchlets and frequently the petioles of a red colour. It was cultivated in the Jardin des Plantes at Paris well back into the last century, and is conjectured to have been sent to France by the French missionaries who were amongst the earliest plant-collectors in the Mississippi region.

*V. LABRUSCA* (Northern Fox Grape).—Before the introduction of *V. Coignetia* this was perhaps the most striking and effective of the true Grape Vines in cultivation in Britain. Its leaves are amongst the largest, both they and the young branchlets being covered on the under surface with a rusty-coloured or sometimes whitish down. They are of stout texture and vary considerably in shape, sometimes entire, sometimes deeply lobed. There is almost invariably a tendril or a fruit-stalk opposite each leaf, constituting the distinction between this and the four species previously mentioned, which has already been referred to. In a wild state the fruit has a musky flavour, but by cultivation it has been much improved, and numerous varieties of the species are grown in the United States. Englemann says that although not large as a rule, it occasionally reaches the tops of high trees. In England it proves to be a strong grower and deserves a high place amongst ornamental climbers.

*V. VULPINA* (the Southern Fox Grape).—A very distinct and handsome species, differing from the American species already enumerated in its close bark, which does not peel off. The leaves are small (2 inches to 3 inches across) and rounded, usually smooth and shining on both surfaces, and although coarsely toothed, rarely distinctly lobed. The species is worthy of note, as its small, bright green leaves may be used as an effective contrast with those of the *Labrusca* and *Coignetia* types, or may prove suitable in situations to which the larger-leaved species would not be adapted. Other American Grape Vines worth growing but possessing no particular value beyond those already described, are *V. rupestris*, *arizonica* and *cinerea* (the downy Grape), all of which are in the Kew collection.

*V. QUINQUEFOLIA*. This, the far-famed Virginian Creeper, is better known as *Ampelopsis quinquefolia*, or as *A. hederacea*. Introduced,

according to Loudon, in 1629, it has during the long period of its cultivation in this country become almost as well known as any of our native climbers. So far as autumn colour is concerned it is the finest of the American Vines, its foliage changing in the fall of the year to various shades of crimson, scarlet and purple. The leaves consist of five (occasionally one or two less) leaflets, which are broadly lanceolate, with a few coarse teeth on the terminal half. For covering arbours, walls, verandahs or old tree stumps there is no climber which produces so luxuriant an effect in so short a time as the Virginian Creeper does. The following varieties are in cultivation: *Major*, *incisa*, *hirsuta*. Their distinctive characters are indicated by the names. Deserving of more detailed mention is *Ampelopsis muralis*, a name current in this country and on the Continent, whilst the same plant is known in America as *Vitis Englemanni*. It is a distinct form of the Virginian Creeper, possessing the same shaped leaves and developing equally, or even more, brilliant autumnal colours. Unlike the ordinary form, however, which requires support if it is intended to cover a wall, this is self-supporting, and will attach itself as firmly to any suitable surface as *V. inconstans* does.

*V. ARBOREA* (*Ampelopsis bipinnata*).—A species of considerable beauty of foliage, differing from any other North American species here mentioned in having bipinnate leaves. The numerous leaflets constituting a single leaf are small and deeply toothed. It is not a quick grower in this country, and is naturally of a shorter and more bushy growth than is characteristic of the Vines generally. Introduced from the S. United States in 1700.

#### ASIATIC SPECIES.

*VITIS COIGNETIA*.—So far as this country is concerned, this is the newest and in some respects the most beautiful of all the Vines. It is a native of Northern Japan, its nearest ally under cultivation being the North American *V. Labrusca*. For many years a Vine clampering over a tall Pine in Mr. Anthony Waterer's nursery at Knapp Hill has been at once a puzzle and a delight to all who have seen it. The foliage before falling turns a glorious crimson, making one of the most beautiful of autumn garden pictures. Up to within the last year or so, however, its identity could never be ascertained, no specimens in herbaria or in living collections exactly matching it. There is now every reason to believe that it is *Vitis Coignetia*, of which numerous plants have been lately raised in this country from seeds collected in Japan. The under-surface of the leaf is covered with a woolly down, which in Mr. Waterer's specimen is reddish brown: the colour, however, varies; in some instances it is nearly white, but similar variations are met with in other species. The species is named in honour of Mme. Coignet, who gathered the seeds in the mountains of Northern Japan, and sent them to France in 1875. Seeds were again introduced to that country in 1884, but until recently very few plants appear to have reached England. We may now hope that in a few years' time it will constitute one of the most striking features of our gardens in autumn. The leaves are cordate, irregularly toothed, and measure each from 6 inches to 10 inches across. In size of leaf and vigour of growth it is at least the equal of any other Vine in cultivation. It has hitherto proved difficult to propagate by the usual methods of eyes and cuttings, and with only very limited success when layered. It can be grafted on several of the American species, but in view of its superior vigour that is not likely to be a satisfactory method, and now that it is well known there is no likelihood of a dearth of seeds sent direct from Japan.

*V. HETEROPHYLLA* (also grown as *V. brevipedunculata*).—The Hop-leaved Vine, which is the variety of *V. heterophylla* known as *humulifolia*, is the most generally grown and most beautiful of the various forms of this species. Unlike any of the species hitherto mentioned, it has, besides its handsome foliage, the additional recommendation of producing in autumn a pro-

fusion of pretty turquoise-blue berries. The leaves are smaller than in the common heterophylla and are usually more deeply lobed. This Vine requires in most places a position on a wall in order to induce it to fruit with proper freedom, and appears to succeed better where it is restricted for root room. It was originally discovered by Dr. Bunge in North China, but has since been found in Japan and Corea. A variegated form of *V. heterophylla* is very pretty, the foliage being mottled with white or faint pink. A sheltered, sunny position is necessary to develop the variegation to its full extent.

*V. INCONSTANS* (SYNS., *Ampelopsis Veitchii* and *A. tricuspidata*).—The unfamiliar name here given is the one that properly belongs to the plant so well known as *Ampelopsis Veitchii*. It is the most beautiful of all the species in the *Ampelopsis* section of the genus, and for covering walls has no rival. As is the case with so many of the Vines, this shows great variety in the shape of the leaves. In young plants the leaves are small and very often scarcely lobed at all, whilst in older ones they are cut into three lobes and occasionally into the same number of separate, short-stalked leaflets. This tendency to variation shows itself also in the colours the leaves put on in autumn. In the best forms the foliage assumes various rich tints of purplish red and crimson; whereas others have a large admixture of brown in the colouring. There is also a form whose foliage has a bronzy hue more or less throughout the season, but especially when young. This climber is planted abundantly in Oxford, and more than once have I been charmed in autumn by the glorious masses of rich colour on some of the walls and gateways of the college quadrangles. It is a plant of the very easiest propagation by means of cuttings. A native of Japan and introduced about 1868.

*V. ROMANETI* is a species of recent introduction, and one which promises to prove very distinct and vigorous in habit. It has large leaves, of much the same size and shape as those of *V. Coignetia*, but it differs from all the Vines in cultivation (except *Spinovitis Davidi*) in having the branches and petioles covered with bristles or stout hairs. It was discovered by the Abbé David in the Shen-si province of China.

*SPINOVITIS DAVIDI* is nearly allied to *V. Romaneti*, having the same bristly or even prickly character. Carrière says, however, that seedlings raised in France exhibit much variation in this matter, the bark of some being perfectly smooth. In any case the character is not one of sufficient importance to justify the creation of another generic name. In the Kew list of trees and shrubs it is referred (under a query) to *V. vinifera*. It was found by the Abbé David in the Shen-si province. Both this and *V. Romaneti* assume purplish red autumn tints.

*V. VINIFERA*.—Of the numerous varieties of the common Grape Vine the following may be alluded to: *Purpurea*.—This is one of the deepest purple-foliaged plants we possess. Although the colour becomes most intense in autumn the leaves have a bronzy purple tinge from the first. It is not so quick a grower as the ordinary form. *Var. laciniosa* or *apiifolia* is the Parsley-leaved Vine. Its leaves are very deeply cut, frequently into several leaflets, which are again deeply lobed. Besides these there are the Miller's Grape, with smallish leaves covered with white down, and the "Teinturier" Grape, the leaves of which assume a beautiful elaret colour before they fall.

Brief mention may be made of the following Asiatic species: *V. ficifolia*, a distinct plant with small round-lobed leaves like those of the Fig; *V. flexuosa*, *V. Thumbergi*, whose foliage turns red in autumn; and *V. serianefolia*, an interesting species of the *Ampelopsis* group, with tuberous roots like a Dahlia, and with palmate or bipinnate foliage. All these are natives of China and Japan. *V. himalayana* is a North Indian species with striking trifoliate leaves.

W. J. BEAN.

## THE POPLARS.

THE following species and varieties of Poplars are now in cultivation:—

*POPULUS CANADENSIS* OF *MONOLIFERA* (the Canadian or Swiss Poplar).—A well-known and easily distinguished species.

*P. C.* VAR. *RÉGÉNÉRÉ* (or *Peuplier régénéré*).—This is of a much more branching habit than the type, and grows straighter and more vigorously, attaining in fifteen years as large a size as the type does in twenty years. As a timber tree it is very highly thought of. Being very much in request, some growers have attempted to sell it under various new names, amongst which we may mention *Peuplier Eucalyptus*, under which title we have seen it shown at a great exhibition. It is one of the most valuable varieties of Poplar.

*P. C. AUREA* VAN GEERTI.—A variety with golden-coloured foliage.

*P. HYBRIDA BEROLINENSIS* (the Berlin Poplar).—A hybrid between *Populus laurifolia* and *P. canadensis*, distinguished from the last-named species by its more pyramidal habit of growth and its longer and slenderer branches. The leaves also are broader and the roots do not spread so much.

*P. LAURIFOLIA VIMINALIS*.—This is not a vigorous-growing species, and is not cultivated to any great extent. It is of slow growth, with a low, tufted habit and peculiar looking leaves.

*P. CERTINENSIS*.—An Asiatic species, as yet rare in cultivation. Leaves elongated and glistening, a novel feature in the genus *Populus*.

*P. FREMONTI*.—A species with elongated leaves, received quite recently from Colorado.

*P. GRANDIDENTATA*.—A North American species with broad, dentate leaves.

*P. G. PENDULA*.—A variety of the preceding with weeping branches.

*P. HETEROPHYLLA*.—Leaves heart-shaped. Introduced from N. America, and as yet not generally known by the trade.

*P. SIMONI*.—Foliage very distinct. Introduced from China.

*P. ANGUSTIFOLIA*.—A small-sized tree, with shoots of a light yellowish grey colour and lanceolate leaves. Introduced very recently from Colorado.

*P. MEDUSA*.—Introduced from N. America.

*P. EUGENI*.—A peculiar-looking tree, of very rapid growth and pyramidal habit.

*P. TREMULA* (the Aspen or Athenian Poplar).—An indigenous species, growing to a very large size, and owing its specific name to the tremulous motion of its leaves when stirred by the gentlest wind. It grows well in all kinds of soil, and especially so in soils of a light character, sending out its roots to great distances and producing numerous suckers.

*P. TREMULA PENDULA*.—A variety of the preceding species, with weeping branches.

*P. ALBA* (the Abele or White Poplar).—A well-known indigenous species.

*P. ALBA NIVEA* (the White Dutch Poplar).—An improved variety of the preceding species, remarkable for the snow-white colour of its leaves and bark.

*P. ALBA MACROPHYLLA*.—The leaves of this are broader than those of the preceding variety.

*P. ALBA PENDULA*.—A variety of *P. alba* with weeping branches.

*P. BOLLEANA PYRAMIDALIS*.—A remarkable and valuable variety, not much known as yet. A nurseryman of Calvados states that he was the first to receive this from a Russian botanist who was collecting in the Caucausus. Stolen from this nurseryman by one of his employes and sold to a firm at Orleans, it was first sent out by this firm.

*P. CANINENSIS* OR *CANESCENS*.—A species indigenous in Normandy. Leaves like those of *P. tremula*, but broader, whitish and smooth. Not knowing the scientific name of this species, I had it identified. About ten years ago a small shoot of it chanced to spring up in the heath soil of a plantation of *Rhododendrons*, where I allowed it to remain, and the tree now measures about 14 inches in girth and is a splendid specimen.

*P. NIVEA AUREO-INTERTEXTA*.—A variety the leaves of which are variegated with golden coloured interlacings.

*P. CANDICANS* OR *BALSAMIFERA* (Ontario Poplar).—A handsome, erect-growing species with large leaves, the glutinous buds of which give out a strong balsamic odour in spring.

*P. CANDICANS ELONGATA*.—An interesting variety of the preceding species, or, according to Professor Dippel, the offspring of a cross with *P. laurifolia*.

*P. TRICHOCARPA*.—A new kind from N. America, with still broader leaves than those of *P. candicans*.

*P. TRISTIS*.—Another variety of *P. candicans* with small leaves, dwarf habit of growth, rugose bark, and foliage of a very dark tint from its first appearance.

*P. ANGULATA* OR *MACROPHYLLA*.—Bark thick and angularly ridged. The leaves of this species are larger than those of any other known Poplar.

*P. SCAROLENS*.—A sub-variety of *P. candicans* with shorter branches and stouter buds, giving out a still more powerful odour than its parent does.

*P. NIGRA BETULIFOLIA*.—Resembles the Italian Poplar, but has smaller leaves like those of the Birch tree.

*P. FASTIGIATA* (the Lombardy Poplar).—Well known as the most pyramidal in growth of all the Poplars.

*P. FASTIGIATA ROBUSTA*.—A new and improved variety of the preceding species, which it excels in vigour of growth. It is anticipated that it has before it a future of note.

*P. PLANTIERIENSIS MASCLA* AND *P. P. FEMINA*.—Forms of the Lombardy Poplar, of which the sex has been fixed by arboriculturists.

In addition to the foregoing we may mention *P. cordata* and *P. rotundifolia*, varieties whose specific names sufficiently indicate the peculiarities of their foliage, and, concluding with the famous *P. euphratica*, we think we shall have enumerated all the kinds of Poplars which are now known. This last-named species was sent to us from the country of *Salix babylonica* a few years ago, and is as yet hardly known to European planters. It appears to be an exceedingly singular kind of tree, as when it is fully grown its foliage undergoes an extraordinary transformation, and travellers inform us that the same tree will exhibit on its lower branches leaves as round as those of the Judas tree (*Cercis siliquastum*), while the leaves on the upper branches have all the appearance of Willow leaves.—LETELLIER ET FILS, *Cult. (Cultures)*, France.

**Rhododendron Queen of Dwarfs.**—Where small plants are required this is one of the very best varieties in cultivation, for it is of a neat, bushy habit of growth and will flower profusely when little more than 1 foot high. The individual flowers are white, with the edges of the petals prettily crimped, and they are borne in such a compact rounded cluster as at a little distance to appear like one bloom. This particular variety was raised by Mr. Davis, of Ormskirk. One of its parents was *R. multiflorum*, and from it the dwarf habit and remarkable full flowering character of many of his hybrids have been derived. A second variety from the same source is *Bridal Bouquet*, which appears to be even dwarfer than the last-named and with rather smaller flowers of the purest white. These two forms are only slightly fragrant, but the Ormskirk seedlings with scented blossoms are now well known and largely grown. Of these, the weakest grower, Countess of Derby, has the finest blossoms, but all are very beautiful. The other scented varieties are Countess of Sefton, Duchess of Sutherland, Lady Skelmersdale and Mrs. James Shaw, all of which will flower well in pots 5 inches in diameter and upwards. These *Rhododendrons* should be struck from cuttings and stopped freely during their earlier stages in order to ensure a bushy habit of growth. A little more warmth than that

required for established specimens may be given to the young plants at first, as they will grow more rapidly so treated, but thrips are liable to be a trouble if too much fire-heat is used. Even in pots only 5 inches in diameter the plants will remain in good health for two or three years without re-potting, provided a reasonable amount of care is taken of them. A very good plan with *Rhododendrons* of this class is, after flowering to keep them in the greenhouse for a time, giving them frequent syringings; then in the summer they can be plunged out of doors in a sunny spot. Upon the treatment then given them depends the future display of bloom, for they need to be carefully watered, above all being particular that they are not allowed to suffer from want of water, and a good syringing when the heat of the day is past will also be of great service. The plants may occasionally be turned round in order to expose the whole of the plant to the same amount of sunshine, thus ensuring the thorough ripening of the wood and consequent display of bloom. For plunging material good cocoa-nut fibre refuse is the best.—H. P.

**Daphne Blagayana.**—Among a group of plants exhibited by Mr. T. S. Ware, of Tottenham, at the meeting of the Royal Horticultural Society on March 26 was a pan of this *Daphne*, and very pretty it was, the fragrance of its flowers being especially noticeable. It is a distinct and pretty species, not much known even now, though it was first discovered by Count Blagay on his estate at Lorenzburg, in Carniola, as long ago as 1837. When a coloured plate of it was given in *THE GARDEN*, August 31, 1878, it was almost unknown in this country. It is not invariably seen in a flourishing state, and I have found apparently healthy specimens die off in a few days without any visible cause. This *Daphne* is of a loose, straggling habit of growth, the creamy white flowers, which become purer in tint after a few days' expansion, being borne in small, compact clusters on the points of nearly every shoot. It does well as a rockwork shrub, that is, where the roots are so situated that they are at no time dried up, and partial shade seems to suit it well. When the roots are in the fissures of a rock they will travel downwards for a considerable distance, and are then rendered independent of superficial moisture. It is usually propagated by grafting, but from its spreading, partly procumbent habit of growth, layering can be readily carried out, and plants obtained in this way are more likely to form permanent specimens than those grafted. In the open ground the usual time for this *Daphne* to bloom is during the month of April or May.—T.

**Churchyard plants.**—The illustration on page 188 recalls to mind a query that appeared last year in *THE GARDEN* as to the most suitable trees and shrubs for churchyard planting and a suggestion that there are many things that might be used instead of relying on the few formal trees usually associated with such planting. I think *Spiraea arifolia* was included in the list; if not, it certainly deserves a place, being one of the best shrubs of English gardens. It may be used as a single specimen on the grass or grouped in the foreground with larger deciduous or evergreen trees. Its feathery plumes are, for instance, seen to great advantage when backed by the foliage of the English Yew. *Rhus Cotinus* is another feathery shrub that can be used in a similar position. Other shrubs that make very nice single specimens from 8 feet to 10 feet high and that are very beautiful when in full bloom are the double form of *Deutzia scabra* and the Virginian Fringe Tree. Two plants of somewhat larger habit one could safely recommend are the double-flowering Almond and the Snowy *Mespilus*. All the foregoing are of light, graceful habit, and I think this should be one of the first considerations in selecting trees and shrubs for churchyard or cemetery planting. There are not many native deciduous trees suitable, and, indeed, most of the exotics would attain to too great a size unless kept within bounds by occasional pruning. If this could be done with care and discrimination so as

not to destroy the symmetry of the tree, an occasional deciduous Magnolia, Salisburia and a few of the best Acers might be used. The objection to trees of a sombre, formal appearance would apply respectively to Pines, Thujas and most of the Abies. Cedrus atlantica and the deciduous Cypress would rank among the most graceful of the Coniferae, and Abies Menziesii is by no means a formal tree, but I find it is a little particular in the matter of soil, plants getting very ragged with us after growing a little over 30 feet.—E. BURRELL, *Claremont*.

#### THE NOBLEST OF EVERGREEN CLIMBERS.

MR. BURRIDGE wrote to us during the frost from the Botanic Gardens, Trinity College, Dublin, that he had just gathered over sixty varieties of the Ivy. This is a very instructive fact for all who care for beautiful hardy plants. Surely nothing that comes from the tropics or any other country can be more delightful than these Ivies may be made by those who grow and place them well. They are so simply grown, that few people ever think of the best ways of placing them so as to get a fair idea of their great beauty.

In many parts of North America and Northern and Central Europe the Ivy is not hardy, and people would give much for the privilege, which we may enjoy, of making really artistic things of these beautiful hardy northern climbers. We know that Ivy generally grows on a wall, and perhaps it cannot grow on anything better; but it is by no means the only use for it. Many people fear Ivy on trees. We should not hesitate to allow Ivy to grow on trees of secondary value, and, if not allowed to overrun the tree entirely, it will not do it much harm. That is only one way. Sunk fences, banks, walls, are all places in which we may plant our Ivies; and another pretty, though very much neglected, way is that of making screens of Ivy instead of the wretched hedges of Privet we often see cutting up gardens. Where a screen is needed, nothing is more beautiful for it than almost any kind of Ivy. The one most commonly used in that way, and by no means the best, is the Irish Ivy, which is so popular in Continental gardens; but it is better to make a change and use other kinds for this purpose. The screens we speak of are easily formed with trellis-work of any kind—iron, stout wire, Oak slabs, or any like material that may be handiest. Planted in fairly rich ground, the Ivies in a few years will cover the screen. Another plan we like very much is that of growing the choicer kinds of Ivy as pyramids, each on a stout prop, the shoots falling down gracefully. Ivy is very charming in all ways. Where there is a large area of dead walls it is a very wise thing to use so valuable a plant for covering them. Why, instead of the thatch and the rotten things we use for bowers and the like, should we not form wigwams and bowers of this delightful evergreen? Construct a stout and simple framework of the desired shape, and in a belt of good soil round the base plant one or more good forms of Ivy, and leave the rest to time. A roof of Ivy would be very much pleasanter than many things that are used for this purpose, and would not decay in the offensive way common to such thatching material as Heath, straw and Reed. The roof should be well tied together, and an occasional clipping of the Ivy will suffice to keep it out of the power of the wind. We are not sure that, with a little patience and care, it could not be made to do for sheltered sheds in pastures, instead of faggots and other rough material commonly used; and where a sheltered shed is placed near a wood, as is very often the case, the body of the shed might be built back into the wood, so as to leave only the front exposed to the field, and in that way we should protect our Ivy from browsing animals.

Another interesting phase of the question is the tree forms of the Ivy, which must not be supposed to be distinct kinds, as the Ivy itself when fully grown and exposed is very apt to take this

form. The form we generally see is the Ivy in its creeping state, but when it gets fully developed it breaks out into what we call the tree form, which gives another opportunity to enjoy the variety of aspects of this plant. All Ivies are good until we come to the wretched variegated kinds, which are not worth growing; collections of these are sure to disappoint; the so-called variegation is only disease, and it is almost as well that it is so, because if such things grew freely the effect would be far from beautiful—hard, spotty, and unnatural.

Among the more beautiful forms met on the occasion referred to, without noticing the curious splashed kinds, there are the himalaica or Northern Indian Ivy, a very pretty form; atro-purpurea, a leathery looking leaf, and very dark; azorica, a very leathery, Vine-like leaf; triloba or tridentata, a handsome arrow-shaped leaf; obovata, a very pretty slightly bronzed leaf; palmata, a most graceful Ivy for a tree or wall; H. amurensis, a tall, very vigorous kind; scutata, or Shield Ivy; H. Ragneriana, what they call the old Irish Abbey Ivy, an immense Aralia-like leaf, much larger than what is called the Irish Ivy; dentata, a very graceful leaf, massive and leathery too; algeriensis rhomboidea, a spoon-shaped and very distinct leaf, and so on through a long list, scarcely one of which is not a distinct and valuable climbing shrub. It would, of course, be possible to make a very delightful garden of these Ivies alone on walls, rocks, or even the ordinary surface of the ground, with groups of Forsythias or Japan Pear, or any other hardy flowering shrubs one might care for among them.—*Fichtl*.

### GARDEN FLORA.

#### PLATE 1009.

#### CYPRIPEDIUM CHARLESWORTHII.

(WITH A COLOURED PLATE.\*)

AMONG the host of novel and beautiful Cypripediums introduced within the last few years the subject of the accompanying plate takes a very high position. It was originally imported by Messrs. Charlesworth, Shuttleworth and Co., of Heaton, Bradford, from the East Indies, and when exhibited by them at the Royal Horticultural Society's meeting at the Drill Hall in September, 1893, was awarded a first-class certificate by the Orchid committee. That it was deserving of this distinction there can be no doubt, as it is a decidedly beautiful species, and one that is rapidly becoming popular. As will be seen by the illustration, the dorsal sepal is very distinct and differs from that of most other known kinds. The pure white staminode is also a noteworthy characteristic of the species. In growth it somewhat resembles *C. Spicerianum*, but the leaves are marked on the back with rows of dots of a brownish purple tint. Although not a very robust grower, the culture of *C. Charlesworthii* presents no special difficulty. A shady position in a warm, moist house is essential, and the compost may consist of loam fibre, good peat, and chopped Sphagnum Moss in about equal proportions, keeping this in an open condition by a liberal admixture of finely broken crocks, charcoal, and a few pieces of limestone. Until the plants are thoroughly established it is safer in potting to elevate them a little, as this prevents the possibility of water collecting about the axils of the leaves, which is so often productive of injury to newly-imported Cypripediums. A thin compost will also suffice at first, the additional drainage being an advantage, as an abundant supply of water is necessary when

\* Drawn for THE GARDEN at the Royal Gardens, Kew, by H. G. Moon, November 23, 1894. Lithographed and printed by Guillaume Severeys.

the roots are well on the move. The best thanks of orchidists are due to the above-mentioned firm for the introduction of this exquisite species, and as they have apparently imported it in quantity, we may confidently expect many variations from the type as the plants flower. Probably it has been taken in hand by the hybridists ere this, and it will no doubt be frequently heard of as one of the parents of future hybrids. R.

### THE WEEK'S WORK.

#### HARDY FRUITS.

PEACHES AND NECTARINES.—Trees on warm southern aspects will now be bursting into full bloom, and where they are left unnailed as long as possible there should be no further delay in nailing and getting the protecting materials in position. In nailing, use new shreds, as old ones are not free from insect pests. Young trees are often much injured by being given too little space to develop. In training allow ample space for the laying in of next season's wood. Peaches and Nectarines given free play in the way of extension are much less subject to disease. Nailing this season is considerably later, and many may think my advice full late. I am never in a great hurry to do it, as though the trees may be studded with fruit-buds, by careful handling they are readily placed in position, and with dull, sunless weather are best left unnailed to the last possible date. Last season the trees were in full bloom by this date and some fruits set, showing that it is necessary to do the work advised according to season. Some trees flower earlier, but I always leave nailing to the latest moment, then do it quickly, and protect when finished. Trees requiring much pruning should not be left till this late date; pruning may be done earlier, as advised in former notes, but there is little pruning needed if the trees get the necessary thinning and removal of old fruiting wood as soon as the crop is cleared. If shortening back last season's wood has been neglected, it is well to observe that fruiting wood should be cut back to a wood-bud. It is not always easy to determine what are fruit-buds, and in that case the fruit should be removed at the end of the shoot when visible, and the nearest shoot allowed to grow. In training it is well to bear in mind that gross shoots do not produce fruit, and in some cases total removal would be better.

VINES ON WALLS.—These are often used as a cover for naked walls, but in few instances are they grown for the fruit, as in our variable climate the fruit cannot be depended upon to ripen. Many plants are so much neglected that ripening is out of the question, as the roots are never given any food and the shoots get too thick. Good crops may be secured by growing the canes on the single or double cordon system and pruning back to spurs, giving the roots food in the way of liquid manure and surface dressings of soil and manure. Now is a good time to remove useless wood, giving the strong or new shoots ample space. Starved canes cannot be expected to make good wood, and a much better result would be obtained by liberal top-dressing at this season, taking away old surface soil till the roots are reached, and giving new in the way of good turfy loam, bone meal, wood ashes and manures.

APRICOTS.—Many trees will now be in full bloom, so that any notes as regards covering and protecting the trees will be late, but where these fruits are grown under glass covers or protectors I would give timely advice as to moisture. For the past two months the rainfall has been very slight. Few trees fail sooner than Apricots; the roots of healthy vigorous trees should be on the surface, and though watering may not reasonably be expected to begin for some weeks, it is well to see that the protection does not rob the trees of moisture, and to supply the deficiency. Any work left undone in the way of surface dressings to wall

trees may be done; indeed, now is a good time to give food in the way of surface soil mixed with rich fertilisers, as the trees being on the move will call upon the roots for more food. Apricot trees are gross feeders, if the term can be used. They require much food in the way of frequent surface dressings, much moisture during growth and keeping the roots active at the surface. It is much better to obtain a luxuriant growth than to just keep the trees alive. In protecting late trees give only a light airy covering, as too much causes a weak bloom, which though it may set soon turns yellow and drops. Trees in favourable positions and full of vigour will well repay lightening of the crop at the earliest moment possible after setting.

**CHERRIES, PEARS AND PLUMS.**—The first-named will require a light cover, as birds are troublesome near towns. Small birds do much injury just before the blossoms open and in a few days will spoil all chance of a crop. It is well also to protect choice early kinds from cutting winds and frost. The Cherry being the earliest fruit to ripen is always valued on that account. For covering I use a small square mesh fish net, doubled or trebled according to the position of the trees, and there is no necessity for the nets, or whatever covering is used, to reach the bottom of the wall by at least 3 feet. This allows anyone to get at the trees, but to protect from birds it is not of service, as the nets must be fastened to the wall. Pears on gable ends of buildings or walls are often shorn of their crop, as many kinds bloom early. With these, different means to protect must be adopted. I have used Fir branches, and serim canvas cut in widths and run along the main shoots will save early bloom. Choice cordon Pears well repay a little care at this season. The walls of these may be covered in the same way as advised for Peaches or Apricots, but whatever covering is employed it should freely admit light and air. Plums, though often left to take their chance, may often be covered readily by the same material which has been used for Peaches or Apricots. It frequently happens that the earlier bloom is safe and there is little frost, but later a severe frost does injury to Plums, Pears and late fruits that might be saved by protection.

**FIGS.**—The covering used for these trees should now be removed and pruning done, the shoots regulated and placed in position for fruiting. In an earlier note I advised partial uncovering, so as to inure the trees gradually; but the trees should not be left longer, pruning being necessary, and the warm sun will soon cause the new wood to grow freely. Trees that have been tied together so as to save space in covering will require some care in selection of best wood to furnish the wall. It cannot be seen at this date which are the best fruiting shoots of last year's growth, but there need be little pruning if these were kept thin last autumn and the wood thoroughly matured. Should the trees be at all thick, it is an easy matter to go over them as soon as the fruits show, removing any shoots that are barren. In no case should sucker growth be allowed on trees having a good quantity of leading branches. At times one must resort to suckers if frost cripples the older wood. In nailing keep the trees quite close to the walls, as they get more warmth and can be more readily protected. Old trees that have been much neglected should have the gross wood or that which protrudes a long distance from the wall cut away, and though a crop will be out of the question this season, by laying in new wood and giving it ample space, the trees will give a good return next season. Trees allowed to run wild will also need root-pruning. When cutting the roots it is well to give new soil, turfy loam, with a liberal addition of wood ashes, burnt garden refuse, mortar rubble, or other materials that will produce fruiting wood, avoiding manures in the soil, which are best supplied as surface dressings.

**PLANTING FIG TREES.**—There will be great losses in cold, exposed gardens, the Fig being very

tender, and even some with ample protection will have suffered. Vigorous trees will doubtless send up sucker growth, and these must be regulated and encouraged to fill a good space of wall this season, but where planting is necessary, now is a good time to do the work. To avoid future losses give the best position, such as the angle or junction of a wall or corner facing due south or south-west. On the latter aspect I have obtained the best results. It is advisable to restrict the root-run by bricks, tiles, or other means. The soil should be as advised above, and the trees thrive well in a chalky soil, so that when procurable it should be used freely. Plant firmly and give the surface roots every encouragement to run freely, as they delight in an open compost, with liberal supplies of moisture. Doubtless the Brown Turkey is the best all-round Fig we have for either indoors or the open. Young trees are supplied in pots, and it is well to handle the roots carefully, not to shake out like Vines, but to unwind the long roots and merely lay in the soil, filling up and firming as the work proceeds. In

Claret coloured Vine. (See page 250.)

training do not attempt to lay in small wood, but to get leading branches to form the body of the tree. These will soon push out fruiting wood another season.

G. WYTHES.

**THE KITCHEN GARDEN.**

**EARLY LEEKS AND ONIONS.**—Where seed of these two vegetables was sown the first week in February for producing extra large early bulbs, the seedlings will by this time be sufficiently advanced for pricking off either into frames furnished with a gentle warm bed of leaves, or into ordinary rough-made deal boxes. A few growers pot them off into pots 3 inches or 4 inches in diameter, which is in reality the safest plan, as then the young plants can be transplanted with little or no root interruption. In any case good retentive loamy compost should be used, and instead of mixing manure with the soil, place a good layer in the bottom of the boxes or pots over the drainage. Pot or prick off very carefully, spreading out the tender roots like the extended fingers

of a man's hand, and covering them carefully at first with a little of the finest of the compost, and finally making the remainder very firm. Water home, and in the case of pots or boxes give a position near the glass in a temperature of from 50° to 55° at night. Here they may remain for three weeks, when they must be gradually hardened off by removal to an ordinary cool frame, open-air planting being carried out about the third week in May. It is always a good plan to mix a little soot with the compost when pricking out of the seed boxes into pots, this being obnoxious to the terrible Onion maggot.

**MAIN CROP CARROTS.**—In favourable soils that can now be worked and trodden upon without becoming sticky the main crop of Carrots may now be sown. Presuming that the necessary preparation in the form of ridging up to the frost and wind, the incorporation of soot and wood ashes, and frequent surface stirrings since the frost disappeared has been given, all that is now needed is a fine sunny day. Tread first lengthways and then crossways, draw the drills shallow, sow rather thicker than usual, Carrot seed being none too reliable in the open this year, and before filling in give a good dusting of burnt refuse, firm the surface well, and use a fine-toothed rake in order to remove all stones. In regard to varieties, this sowing is best represented by the Intermediate type, although where the soil is deep the Long Red Surrey is a capital sort to grow for late winter use. Veitch's Matchless Scarlet and any of the improved forms of James's Intermediate cannot be excelled either for freedom of growth or quality. Where the soil is but shallow and poor, shorter varieties, such as Scarlet Model, will be found the best. In such soils assistance may be given by a broadcast sowing of some quick-acting fertiliser twice during the growing season in showery weather. The French or Parisian Forcing, which was sown at the commencement of February, will need all the encouragement possible by early thinning, using the Dutch hoe between the rows, and a gentle moistening with tepid water into which a little guano has been stirred. Wireworm and grubs generally do not like guano. If windy weather ensues, the fly will probably appear on the tops. This must be stopped by overhead sprinklings of wood ashes.

**SUCCESSIONAL POTATOES.**—In many gardens Potato planting, even of the earlier section, is by no means completed. Such, however, should now be brought to a speedy close. All second earlys should also be got into the ground, as if left any longer in the store rooms the sprouts will increase in length at a greater ratio than they will do under ground, and therefore be more liable to fall victims to May frosts, as protection to any great degree cannot always be given to large breadths of second early varieties. To those who have yet to purchase the sets I would recommend Snowdrop for this planting. I have proved its excellence for some years, and know it to succeed in many other localities and in a great variety of soils. Another good trait in its character is its long-keeping powers, being frequently eatable late in spring. Sutton's Seedling must also be named, as, all points considered, it cannot be beaten for a second early. I have still a high opinion of Beauty of Hebron, as, although a pink-skinned variety, it has a mealy flesh and a delicious flavour, while nothing can be said against its cropping powers. If grown on wet soils it is somewhat prone to disease, but when favoured with a good warm rooting medium and perfect drainage it seldom becomes affected. A splendid pebble-shaped variety is found in Windsor Castle. This is sure to become a leading Potato where quality and quantity combined are a desideratum.

**MAIN CROPS.**—From the first to the second week in April is a capital time in the majority of cases to plant for the late autumn and winter supply. In a former calendar I advised looking over the stock at the beginning of March, removing all the sprouts that had formed during winter and laying them out not too thickly in outhouses, merely covering with litter should the nights be frosty

Where this course was followed all the sprouts that have since formed may be allowed to remain on the tubers, as they will be short and stout; and as late Potatoes are usually planted at a good depth, no fear need be apprehended of injury from frost, at least in ordinary seasons. Where these later crops are grown in fields the common practice is to fork farmyard manure into the trenches and to place the sets on it, afterwards filling in. This is all very well on moderately light soils, but to adopt it on strong ground, particularly that not over well drained, is to court disaster. Far better is it in such cases to forego the manure in the first place and to apply it later on in the shape of broadcast sowings. Strong farmyard manure in wet seasons often does incalculable harm by inducing a rampant and late growth at the expense of the crop, and is more-over the forerunner of disease on heavy soils. An error often committed in preparing land for field crops is using dry, husky manure instead of solid spit manure. The former is often so dry and hard that, should the summer prove a dry one, it is found in just the same condition at lifting time, having acted simply as a sieve for what little rain there was. If the land has not been well worked, postpone planting until this is the case, as this is most essential; indeed, is often of more importance than all manures. A good selection being very important, the under-mentioned may be depended on to succeed in the majority of soils: Schoolmaster, one of the best market Potatoes in cultivation, the number of years it has been grown, and that largely, being the best proof of its merits; Lady Truscott, oblong in shape, a heavy cropper, of fine quality, and one which, although it may be lifted and eaten in September, will keep sound and good till spring; White Elephant, objected to by many on account of its liability to become coarse, is nevertheless a good and profitable Potato grown on poor land or where an impoverishing crop has preceded it, flesh then mealy and good; Renown, a splendid new Potato, almost as round as a cricket ball, cropping most freely, keeping well, and unsurpassed for eating purposes; The Bruce, highly spoken of by some, is so similar to Magnum Bonum as to be indistinguishable from that variety. For growing in all soils and climates I think the Magnum is still unbeaten.

**SMALL SEEDS, SECOND SOWING.**—The second week in March I recommended a sowing of Cabbage, Brussels Sprouts, Cauliflowers, and other early autumn maturing vegetables in gardens favoured by shelter and where the demand was great and constant. In such places a second sowing on a somewhat larger scale may now be made of the late autumn section of green crops. In small gardens where no houses or frames exist, the earliest sorts of Cabbages, Cauliflowers, and Lettuce should also be sown. I always sow Cooling's Matchless Broccoli at this date, one of the hardiest and very best of spring varieties, but one requiring a long season of growth. In the south the middle of April would probably be soon enough. Snow's may also be sown now for December use, although for my own part I prefer Backhouse's Winter White, it being more certain as to date of heading in and, I think, also somewhat more hardy. The majority of the Broccoli may stand over till the mid-April sowings. A little seed of the taller varieties of Brussels Sprouts may also be sown, as if the season is fine and forward earlier batches of the dwarfier sorts are apt to develop miniature Cabbages instead of hard knobs; whereas the later sown seed of Scrymgeour's Giant and similar strains which really need a longer season of growth produce perfect sprouts and plenty of them. Where only one sowing is made the present is about the best time to make it, choosing an intermediate variety. For such gardens also Cocoa-nut and Enfield Market Cabbages will be as good as any, both being very reliable and following each other in the order named. Pearl and Autumn Giant Cauliflowers would answer best, and Alexander Cos with Continuity Cabbage Lettuce will be found very suitable. If seed of Self-protecting Autumn Broccoli is sown now, good heads will be forth-

coming from the end of October throughout November, a sowing later in the month being best for plants to continue the supply from that date till the new year with protection.

**RADISHES.**—These may now be sown at intervals of a fortnight, Wood's Frame and French Breakfast being the best till April is out, when the longer red and Turnip varieties answer best. If the latter are sown too soon in the year they grow slowly, and are consequently hot and stringy. A nice sunny position will be advisable until May, when a cooler aspect should be chosen. Attend to thinning out those growing in cold pits and home-made frames, giving occasional soakings of tepid water, as Radishes are moisture-loving subjects.

**GLOBE ARTICHOKE.**—These will be extremely scarce this season, as the majority of stools, even on warm soils and where protected, have been either killed outright or so weakened, that a late and puny growth is inevitable. Where growths start from the base of the clumps it will be well to sever a number of these from the parent and pot them up, afterwards placing them in a cold frame and protecting from rains. These will grow into fairly large plants by June, when they may be transplanted into freshly prepared ground well enriched with manure. Sowing seed is very risky, as so often the produce is utterly worthless. At times, however, this is compulsory, when the only plan is to mark the most worthy plants when yielding and to take offsets from these in spring, casting the rubbishy plants away.

**CARDOONS.**—Where these are much in request, a small sowing may be made on a warm border, or, better still, in a box in a greenhouse. These will come in for autumn use, the main sowing being deferred yet for a little.

**SEED BEET.**—Any roots of special strains intended for stock may now be planted on rich soil in an open and sunny position, the crowns being covered on cold nights with flower-pots for the first three weeks. As soon as growth commences a watch must be kept for sparrows, as these pests often divest the roots of every morsel of leafage. When this is the case a secondary growth has to be made, which is often too late to produce seed-stems in time for ripening satisfactorily. Wood ashes sprinkled over the crowns in showery weather will often prevent birds at taking them.

**SOWING ASPARAGUS.**—Seed either for producing roots for forcing or for the formation of ordinary beds may be sown now. If for the former purpose an open quarter should be selected, shallow drills drawn, an alley being left between every four rows. This space will allow of hand-weeding being carried out without trampling amongst the young plants. Burnt refuse may be used in the drills after sowing, as sometimes the seed is badly attacked by grubs. When the seed is saved at home it should always be taken from plants that bear a few large berries in preference to those which yield large numbers of small berries, the former always producing the best Asparagus. Any convenient sunny spot will do for sowing the seed for nursery work, 1 foot apart being a good distance between the rows.

**SOWING SEAKALE.**—This also should be sown during the early part of April, and where for permanent beds, to be forced by pots and leaves, the soil must be rich and sustaining. Four rows to each bed is a handy number, the seedlings being duly thinned out to the required distance some 3 feet from each other. Where sown for producing crowns for forcing at the end of the second year, 18 inches from row to row and 15 inches between the plants when finally thinned will answer. Where ground is plentiful 6 inches more may be allowed. Both the Lily White and ordinary varieties should be sown, the latter forcing the most readily during November. Rather shallow sowing is important. J. CRAWFORD.

**Onion Rousham Park.**—This, is I consider, one of the best keeping varieties grown. For years I have sown it with James's Keeping and Bedfordshire Champion—two of the best keepers

we have; but till this season I have never had the bulbs frozen for so long a time, and the variety named is equal to the late keeper, being sound and good. In advising the growth of the above I do not mean that huge bulbs were grown, as these do not keep—at least, I have heard such is the case. I do not grow for exhibition, and therefore have no need of the gigantic bulbs, but my opinion is that they are bad keepers, and this brings me to the point—the value of Rousham Park for what may be termed general use for winter and spring supplies when the seed is sown in the usual way, thinned, the bulbs well ripened, wintered in an exposed loft or room and merely protected from damp. This variety is somewhat after the White Spanish type and valuable for its mild eating, so that it may be termed a good all-round variety. Those who desire may grow it to a large size by sowing in heat, but I do not advise it for supplies at this date, as medium-sized, well-ripened bulbs are best.—W. S. M.

## ROSE GARDEN.

### NOTES ON ROSES.

SOME special treatment will soon be necessary among our climbers under glass if we are to secure the best of wood for another season's forcing. It is absolutely necessary that healthy and well-ripened growth be obtained if we are to have a good show of bloom early next year. We need get this as early as possible, so that a brief period of rest may be afforded before the plants are re-started for winter bloom. Our early climbers have finished flowering and will now be cut down; not at one operation only, but in two at a month's interval. Culture with a view to securing good wood should be commenced at once. If we look at this class of Rose in the open air we find it does not cease growth in the least during spring and summer. Even while the last blooms are opening young shoots are actively breaking from around the base. To give any kind of check to these is a great mistake, as not only does it lengthen the time necessary to make wood of the desired length and strength, but we seldom get wood of the same high quality. At no time can we grow our climbing and other Roses under glass to greater perfection than the present. Sufficient light and warmth are available without the need of dense shading from a powerful June and July sun. While many are still growing their climbers I trust mine will be maturing themselves in the dry autumn air. Even grafted plants of this year's working are carrying rods of 3 feet and upwards.

A word upon this spring pruning under glass. It is practically the same as summer pruning in the open, our Roses being in a similar condition in each case. As the wood which has just flowered is of scarcely any value, there can be no good gained by retaining it; rather the contrary, for then we are not only providing more room for the new growth, but diverting the whole of our plants' strength to the production of really useful rods. We follow this plan with pegged-down Roses in the open. Pruning is, or should be finished in all but a few cold localities. The majority of us are content to wait much later than usual this season. Very little long growth will be left this spring after the dead wood is removed, and as much of what remains will be crippled, I would recommend that we cut harder than usual. Indeed, our main hope lies in shoots from the base, and there is very little good in retaining wood that will at best produce only growth of moderate quality. In another note I have spoken of how sadly our Roses look in the south, and from a recent visit to the eastern and midland counties I believe we are much the harder hit of the two. Absence of snow was a great misfortune.

Once more turning to our Roses under glass, I would point out the need for a shift in the case of very young plants. My own, that were rooted from cuttings a little later than this last year, were

potted into 3-inch pots early in January and are now being placed into 6-inch pots. Own-root Roses enjoy a more porous soil than those worked upon the Brier stock. A slight shade will soon be afforded to our Rose houses, not so as to darken in any way, but barely sufficient to break the fiercest of the sun's rays. Under these conditions and not otherwise we can afford a moist atmosphere and an occasional gentle syringing during the prevalence of very bright weather. Air that is alternating between extremes of dryness and moisture, with wide changes of atmosphere, will not suit Roses. Liquid manures will be sprinkled about when damping down as well as freely afforded to all plants not recently repotted. We cannot get colour and quality in the flower without having the same in the foliage. Rather more flowers of sulphur will be added to the syringing solution during this trying time as regards mildew, but we shall still keep both this and liquid manures far weaker than many use, preferring to use them more freely rather than run the risk of overdoing in strength. R.

#### AMONG THE ROSES, MARCH—APRIL.

It has been a matter of surprise to me that more complaints and regrets at the severe loss occasioned during the frost have not appeared in the gardening press. After far less disastrous winters we have had notes from many quarters. Certainly they never had a worse appearance here, and the state of our beds is indeed deplorable. Good plants of many varieties are killed outright. The Hybrid Teas seem very hardy as a class. Caroline Testout, Viscountess Folkestone, and Grace Darling are almost untouched. Now that our beds of dwarfs are pruned, they present a most bare appearance. Many varieties are cut down to the ground line, and with those least affected it is only here and there that any of last summer's growth was in a fit state to leave. On the walls and fences it is little better, nor is a very sheltered garden of my neighbour's any great improvement upon our own exposed plants. I fear we have not a plant of Climbing Perle des Jardins, Lamarque, and the white Banksian alive. Somewhat strange to record, the Fortune's variety of the latter has withstood the cold well, although side by side with the white Banksian. Unfortunately, this is the solitary-flowered kind, and of very inferior merit to the true white Banksian, although frequently passed off as such. Kaiserin Friedrich, one of the Dijon Teas, is even more hardy with us than the old Gloire de Dijon, and l'Idéal also stands well.

Pruning was an exceedingly simple matter, as after the dead wood had been removed we had very little left. That climbing Roses must be a failure this season I think all will admit; 40° of frost were registered by a neighbour with a tested thermometer, while from 25° up to 35° were frequently reached. When so many shrubs are killed we need wonder little at the fate of our Roses. Last year at this time we were looking forward to a delightful season; with the wood sound and growth breaking freely, it seemed that nothing short of a late spring frost could prevent a good summer display. This, however, we experienced both at the end of May and June. At present very little of our Rose wood is breaking, and there is not the slightest prospect of a good Rose season from any but dwarf maiden plants. Once more are our standards terribly injured or killed outright in a large number of cases. Even those upon the very short stems are almost as bad. A day or two back I was looking over some plants of a friend's who had protected with Bracken, and added some straw when the weather became so severe. There is a little more live wood upon his than mine, but this is hard hit, and much of it will be cut away. The dwarfs that were covered with soil at the base look better, although even here there is considerable injury.

When we turn to the budded dwarf stocks of last summer there is a better outlook. Both upon the Manetti and Brier in seecling and cutting form the majority of the buds look well, although

very backward. No time should be lost in cutting away the stock of these. A sharp knife and the left hand pressed firmly around the collar of the plant just below the Rose bud will allow of a cleaner and more healthy cut than that from any secateurs. If a knife is used thus, I prefer to cut down close to the bud, but should the secateurs find favour, it is well to leave 1 inch or 2 inches of the stock. I would adopt the same plan with budded standard Briers.

As Rose growth progresses we shall need to draw a little of the surrounding soil towards the bud. It softens the stock and encourages mere uniform swelling of that and the Rose. This is not all, as it also affords good support against wind. We cannot tie them until growth has progressed several inches, but soil around the base keeps them safe and helps the union at the same time. When cutting back the stocks and previous to earthing up we must keep a close look-out for suckers. These push early and are generally prominent enough to be easily seen by the time we need draw soil around. Cut them out deeply so as to eradicate the eyes usually found around them. With standards also a close and early look round for suckers and breaks from the stem is advisable. When this is done now we not only save much time, but the work is more complete. We can scarcely give too much care in sticking and tying our maiden Roses when growth is sufficiently advanced. RIDGEWOOD.

**Among the Roses in March.**—What remarkable weather contrasts we have season after season. Last year at the present time we were looking forward to a glorious season; the wood had come through the winter safely, everything looked promising, and plants were bursting into growth. In fact, our chief concern was the earliness of the season and fear of later frosts in April or May. Nor were these without reason, seeing that for so many years we have experienced keen frost at that date. Both in May and in June we had frost of sufficient severity to blacken many subjects besides Roses. For weeks afterwards we saw the sad effects of this cold wave. But there are no signs of early growth this season. To-day (March 7) I have taken a careful look round, and I do not think that among the standards and half standards the survivors will average more than one in six, while the majority of the dwarfs are killed to the ground line. We certainly have had a more severe time for Roses in mid-Sussex than ever before. Laurels and Mahonia are quite killed in many places, and the protection of snow was not accorded this district, although a few miles away a considerable amount was lying during part of the severe frost. Here, unfortunately, we had the full force of keen wind with no snow, and the result is greater havoc among Roses than I have noticed in many other instances. I had hoped to be able to give a better report than this, more especially with such a steady and favourable general thaw; but Roses are much too hard hit in this neighbourhood for the most sanguine to look for even a medium Rose season with any confidence.—P.

**Climbing Niphetos.**—There is no comparison between this variety and the ordinary Niphetos for producing bloom. In fact, while the latter can almost be termed a perpetual bloomer when in comfortable greenhouse quarters, the climbing variety, so far as my experience goes, is really not worth growing where profit is considered. True, it will cover a large space of wall or trellising in a very short time, and for that reason is useful for hiding unsightly places, but that is all that can be said in its favour. It is strange that two Roses bearing the same name, though differing in form of growth, should be so opposite in blooming powers.—J. C.

**Are smooth or prickly-wooded Roses the hardier?**—The results of the present frost should go far towards dispelling the idea that one or other of these is hardier than its opposite. If we take smooth-wooded kinds, we find Paul Neron, Captain Christy, and others very hardy indeed, while Victor Verdier and Horace Vernet are

standing examples to the contrary. Some dozen or more varieties could be named upon each side in support of this. Turning to those with many thorns, where have we a more tender Rose than Rev. J. B. M. Camm, or a more hardy one than *Rugosa rubra*? The Mosses, too, and Scotch Briers are among our hardiest Roses, but equally prickly ones from other sections are not. So crossed and intercrossed have our Roses become, that any visible characteristics are of little guide in this respect. In conversation with an amateur friend a few days back while comparing notes on the state of our Roses and the probable prospects after this frost, he stoutly maintained that the thorns were a needed protection to tender varieties.—R.

**Roses under glass.**—The question discussed by "Ridgewood" at page 159, whether Roses are better grown in pots or planted out will most likely be decided in different ways by different classes of cultivators. Doubtless Roses can be cultivated successfully planted out in a border of good soil under glass, but if the house is filled with them it cannot be very well used for anything else; whereas if the plants are grown in pots they can be removed anywhere during the summer months. Some good growers of Tea-scented Roses in pots will not place their plants out of doors at all, preferring to keep them in the greenhouse or Rose house. I believe this is most desirable if the very best results are to be obtained from large specimen plants for exhibition, for instance. My plan with them is to stand the pots containing the Rose trees on two bricks, or if the flower-pots are large, three bricks. The large hole in the centre for the egress of water is clear of the ground; the water passes freely out and the air passes freely in, keeping the potting material in the best possible condition. Except *Maréchal Niel* and any other vigorous-growing sort of this type, which certainly ought to be planted out, there are no others I would care to grow in that way. All other Teas I would grow in pots. *Gloire de Dijon* and *Mme. Berard* should be planted out, and they will grow quite as strongly as *Maréchal Niel* in suitable soil.—J. DOUGLAS.

#### ROSES DEAD AND DYING.

SUFFICIENT time has now elapsed to determine which among Roses have survived the late severe frost. Evidently enough it is not a question of which varieties or which types have proved the hardiest, as there are numerous losses in all the sections. Once more, however, there is no mistaking the fact of the standards on the common Brier stock being the least hardy of all, and I believe we may safely assume that it is these same naked stems that are the most vital parts of the trees. All the while the stems continue to increase in size and the heads remain in a vigorous, healthy state frosts rarely injure them, but when once they give signs of failing health it only requires a moderately severe frost to finish them up. If what has taken place in various parts of the south-western counties of England is any criterion, there has been an extra large number of standard Roses to root out this spring. Losses there are to account for nearly every winter, but very rarely so many as are to be noted this spring. If this leads to the cultivation of more dwarf Roses and fewer standards, then the lesson will have been profited by and good rather than regrettable harm be the result. There is always an artificiality about standard Roses, and as they also prove by far the least hardy, then the time ought not to be far distant when there will be little or no demand for them. Unfortunately, it is not standards only that have been largely destroyed by frosts, but those who have lost their dwarfs, or what should have been dwarfs or bushes, have only themselves to thank in most instances. Where moderately severe or rational methods of pruning have been adopted every spring there are few or no losses. It is those that have been allowed to grow wild or which have been lightly topped and not pruned as we would prefer to carry out this important work

that have suffered the most. Once allowed to go unpruned for one season they become leggy, produce fewer fine flowers, and do not prove very much hardier than standards. Dwarf Roses that are rather freely thinned out and cut back every year possess far greater vitality, and are much less liable to destruction than are many not so pruned—at least such is my experience—and they rarely fail to bloom grandly. In Mr. Brutton's garden near Yeovil, Somerset, there is a long border devoted to Roses on their own roots, some being struck on the place and some originally on the Manetti stock, but long since rooted off. These great spreading clumps, for that is how they can best be described, are annually pruned to within 3 inches of the ground, not an old stump or growth showing above that height, and also receive a rather heavy mulching of manure, yet in spite of these incentives to strong growth they never fail to flower grandly every summer, and there is not a single loss among them from the frosts. These great clumps might be taken up, pulled to pieces and replanted with impunity, that is to say, might safely be treated similarly to herbaceous plants. Contrast this border of Roses with the hundreds of lightly pruned bushes in the same district and the verdict must be given in favour of the hard pruned ones. Before adopting such a drastic method of pruning I should first, however, prefer to give the plan a trial, and till proven shall continue to prune moderately hard only. By moderately hard I mean the free removal of all spray, the shortening back of growths no stouter than a slate pencil to the second joint, those of the thickness of a lead pencil to the third or fourth bud, and any still stouter to a length of 12 inches to 18 inches. I hold it to be a mistake to be more lenient with Teas than Hybrid Perpetuals, as the aim with the former should be to promote the growth of extra strong young shoots from the underground portion of the stems, these branching and flowering grandly long after the single blooms from small wood are over. Standards generally should also have daylight let into their heads, the rather severe thinning out of the more dense being followed by a foreshortening of straggling growth and the free shortening, as advised in the case of bushes, of the rest. Nor ought those growing against walls to be neglected or wholly escape the pruning knife. Very many of these are in a dead or dying state, and it may be a wholesale removal of dead wood will be all the pruning necessary. Teas in these positions I would, for reasons just given, prune freely. Even the vigorous-growing Gloire de Dijon, Mme. Berard, and Reine Marie Henriette pay for thinning out, some few of the strong branches being well shortened back. Not only does this tend to keep up the vigour of the trees, but the early-formed long and strong branches of the first-named in particular will flower at nearly every joint before the season is over. Lamarque if somewhat hard pruned will produce great branching heads of pure white bloom, and the good old Celine Forestier also pays for being freely pruned. Another newer and popular Noisette, William Allen Richardson, is a strong grower, and most of the branches should only have the unripened ends cut away, and lovely buds will then be produced throughout the reserved portions. In the more favoured districts these long branches may be cut back directly after they have ceased flowering, and fresh growths will then be had for the following year, but, as a rule, thinning out this as well as L'Idéal, a rival of W. A. Richardson, is the best plan, as this leads to the production of quite as many young growths as are needed. Maréchal Niel has been very hard hit, but those who have strong young growths still alive should treat these as advised in the case of the other Noisettes.

Now that there can no longer be any doubt about the losses, owners of gardens are inquiring whether it is too late to replace those that are dead. My advice has been to procure bushes at once, planting and pruning these at the same time. These late-planted Roses, being moved just when top and root growth is commencing, will most probably succeed well, but not if their owners or those

responsible neglect to prune them. It is also of the greatest importance that they have the benefit of a fairly rich, fresh, loamy compost, as it is very certain they will fail in stale soil. Failing to change the soil has led to innumerable failures, and so also has high planting. All dwarf Roses are worked, that is to say, either budded or grafted on to Manetti, seedling Brier or other stocks. All, too, are liable to push up suckers very freely, these, if not detected in time, soon ruining the Rose worked on the original stem. The Manetti stem in particular requires to be buried, and this should be done in all cases, sinking the point of union of stock and scion 3 inches below the surface. This comparatively deep planting does not greatly militate against good root-action, and is partly recommended with a view to causing the Rose or scion to strike root or "root off," thereby becoming in time quite independent of the uncertain stock. Once a Rose is well established on its own roots it is an advantage rather than otherwise for suckers to be thrown up, these eventually taking the place of worn-out older wood. Vigorous dwarf Roses give plenty of wood for propagating purposes, well-matured young wood cut into lengths of about 12 inches and inserted firmly and to half their depth in good strong soil striking, as a rule, quite as surely as Gooseberry or Currant

of Roses, not too rampant in growth, though it will clothe a pillar 10 feet high and flower freely from its base to its full height.—J. C. TALLACK.

## ORCHARD AND FRUIT GARDEN.

### WELL-FLAVOURED GOOSEBERRIES.

THE Gooseberry is valued by those who have not a large quantity of glass to grow choice fruits. It is equally as delicious as any forced fruits when due attention is given the trees in the way of food and protection from insect pests. There is not sufficient attention paid to the trees even in large gardens. They are not given enough room or food and occupy the same ground too many years. Even when badly treated the Gooseberry produces fruit in quantity, but smaller and not well flavoured. This latter point deserves more attention, as though size is meritorious, the flavour of some varieties is equal to that of the best forced fruits grown. Of late years, with extended fruit culture, this fruit has received more at-

*Gooseberry Dan's Mistake. From a photograph sent by Mr. T. Pimlott, Whirley Road, Long Moss, Macclesfield.*

cuttings. The autumn or not later than the middle of November is the proper time to put in these cuttings. A ROVER.

**Own-root Roses.**—The advantages of growing many Roses on their own roots will be well shown this year. To-day (April 3) I have been pruning the H. P.'s, and have had the satisfaction of finding that all dwarfs on their own roots are looking well and breaking strongly. Pruning has to be more severe than usual, most plants having to be cut back nearly to the ground level, but beyond this no harm has been done to the dwarfs, and with a genial spring strong growth appears certain. With standards appearances are entirely different, more than 90 per cent. being killed outright, and on the few that have escaped with their lives future growth cannot be satisfactory. Outside appearances are deceptive, as the stored-up sap is causing buds to shoot from young wood which cannot possibly support them, as the old stems lower down are quite killed. On the walls some few climbing Roses are looking as if they may recover without being cut hard back to the ground, but the more tender kinds, such as Maréchal Niel, W. A. Richardson, Devoniensis, Lamarque, and the Banksians, are killed to that point, and there is no need for hesitation in pruning them. Most pillar Roses are spoiled for this year. I take this opportunity of again recommending Vivid for this work, as it is almost the only one that appears unaffected by the frost. It is one of the freest flowering and sweetest scented

cuttings, and we have had some very fine exhibits of over 150 varieties staged, giving those interested an opportunity of seeing the cropping qualities, colour, and testing the flavour. I do not advocate quantity or variety, as most Gooseberries fruit freely, indeed too freely if they are required for dessert. Thinning is a tedious process, but the fruits thinned may be used. The trees benefit, and there are few fruits more profitable at the time. Should quantities be grown, there is always a ready sale. Many of the best varieties, those which produce large berries, are bad growers, and without attention in the way of pruning, thinning, or supports, a large quantity of the fruits is spoiled by coming into contact with the soil and is soon devoured by slugs. Few fruits are more appreciated by the larger birds when ripe, and the buds in the winter by the small finches and sparrows, so that to obtain good fruit one must adopt protective measures. I recently saw a model fruit garden at The Hendre, Monmouth, the Gooseberry trees being covered over with wire netting and occupying a space between larger trees, such as Cherries. Some of the best kinds had been selected, flavour being the first consideration.

This mode of culture is to be recommended, as if the cost of temporary protection be taken into consideration and the greater facilities

combined with neatness and other details, a permanent protection made with strong iron supports and 1-inch mesh wire is worth adopting. Delicious fruits may then be had much later than one can obtain from trees netted in the open, as when closely netted there is not enough exposure to preserve the fruits. The small dessert kinds must not be overlooked when flavour is required, and these are most subject to the depredations of birds. Such kinds as Early Sulphur, Golden Drop and Transparent, when the trees are well fed, are superior to those one usually sees grown in the ordinary way.

For large fruits the one illustrated, Dan's Mistake, is one of the best kinds grown. It is noted for flavour and cropping; indeed, on our light soil it is the best cropper when size is considered. There are others equal in flavour, but I know none superior of the larger section. This variety is a special favourite in the Lancashire districts, and one often sees it exhibited at local shows in splendid condition. To obtain size, thinning is necessary. Dan's Mistake is a large red fruit slightly covered with hairs, and when fully ripe keeps a long time if the trees are not much crowded. It may not be considered the most profitable kind, as Whinham's Industry is a better cropper and for early fruits superior. Whinham's grows freely in a young state, and I find it our best fruit for gathering when green. The desire to have fruit for tarts or pies at Whitsuntide is still observed, and though impossible to obtain in certain seasons, the newer introductions are most useful for that purpose, as they swell quickly after the flowers set. Such varieties as that illustrated are specially suitable for cordon training. The growths of some of the larger kinds is not so robust as one could wish, but grown as cordons, one can feed freely then and expose the fruits so as to obtain flavour. The trees, too, take up less space and can be readily protected. The cordon mode of culture is worth a trial where Gooseberries are liked for the dessert, but it is well to plant strong trees that have been specially prepared for cordon training, as if bushes are cut back to one growth, the following season they produce so many shoots at the base that the leader does not make much progress. For dessert, flavour being considered, such kinds as Green Gascoigne, Ironmonger, Leader, Red Champagne, Alma, Lady Leicester, Keepsake, Telegraph, Speedwell, and those named previously are all worth special cultivation. G. WYTHES.

**Pear Chaumontel.**—I must plead guilty to being one of those people who have not tasted a good English grown Chaumontel Pear, but, on the other hand, I have grown magnificent fruit to look at. The climate and soil must be very favourable indeed for this Pear to come of good table quality in Britain. I did hear of isolated cases, where the Chaumontel is still grown, of its being of very good quality in the abnormally hot season of 1893, and if such seasons could be more frequent, we might look upon the Chaumontel as being one of our best Pears. I have had sufficient experience in the culture of Pears to also know that outward appearance is no criterion of quality. It was, therefore, a surprise to me to read in "W. G. C.'s" note "so many gardeners are enabled to produce Chaumontel Pears that would be no discredit to the Channel Island growers." If there is any secret connected with its good culture other than a very favourable climate and soil, possibly some of these successful growers will kindly give their experience.—Y. A. H.

**The Glastonbury Pear.**—Judging by the interesting account given in THE GARDEN by Mr. J. A. Porch of the Glastonbury Pear, season makes a wonderful difference in its quality, and

which probably is the reason of this trait being so bad last season. My experience, however, is but slight. Last November Mr. Coleman and myself, who were judging the principal fruit classes at Hereford, came across this Pear in a collection, but it was a stranger to both of us. Being, however, of fine appearance, and as we were on the look-out for quality, the fruits were cut, when the quality proved as bad as it possibly could be. The exhibitor afterwards told me we could not have tried a worse one, but being short of a variety he put it in. I do not wish to doubt the authority of the gentleman named in speaking up for its quality, but it only shows what a variable fruit the Pear is as regards season and climate, and proves how careful one need be in selecting Pears for quality to be depended upon annually.—A. YOUNG.

**Colour in Apples.**—"E. M.'s" note on colour in Apples is very interesting, and proves conclusively, what has hitherto been published in the pages of THE GARDEN, that high colour is influenced considerably by the constituent portions of the soil. Even if these have to be added artificially, as has been done in the garden which "E. M." quotes, it only goes to prove the truth. Quoting from memory, I think it was Mr. Roupell who exhibited before the Royal Horticultural Society fruits noteworthy for their high colour, the result of supplying to the soil those constituents which the results achieved proved the soil was deficient of. It is also a well-known fact that Apples noteworthy for high colour are invariably produced from those soils where iron is present in quantity sufficient for the purpose—the red sandstone of Herefordshire, for example. If it can be further demonstrated that the application of sulphate of iron and soot will materially increase colour, it is well worth our future consideration.—Y. A. H.

**Temperatures for setting Grapes.**—The article by "W. G. C." suggests a few notes on temperatures, as he places these in rather a secondary position. It is quite right, however, that temperatures, however stated, will avail but little if the roots are not in a satisfactory state. According to my experience the state of the weather at the period the Vines are in flower is the best gauge of the temperature to maintain. Like "W. G. C.," I remember an instance, and which I have previously mentioned in the pages of THE GARDEN when writing upon the subject of setting Grapes, of a splendid set of Muscats under a low night temperature, but the days were very bright and warm, hence the difference. If, on the other hand, the days had been dull the results would have been disastrous. I had evidence of this last season, not with Muscats, but with such a speeded free-setting Grape as Black Alicante. For some cause, which I need not explain, the temperature on two nights whilst the Vines were in full bloom was low in the morning. I expressed my fear of the results which would accrue at the time and which proved correct. Small globules of moisture were seen condensed on the stigmas, and which was the result of too low a temperature at night. The days which followed were very dull and wet, and the result was that quite three parts of the berries were stoneless. My advice is to keep up a warm, buoyant temperature at night whilst the Vines are in flower in case of any mishap. The ill effects of a low temperature are perhaps seen more on cold soils than light and sandy soils. Lady Downe's is a Grape which also requires a warm, buoyant atmosphere, and so also do all varieties of Grapes which are notoriously shy setters.—Y. A. H.

**Protecting Gooseberries.**—I have known whole quarters cleared in the neighbourhood of towns by the sparrows; indeed, I have this season during the severe frost been obliged to entirely net over the best bushes. Currants have suffered equally with Gooseberries. Once the birds start on a quarter they clear the trees before they go to fresh ground. Such well-known remedies as lime freshly slaked and dusted over the trees in my case are powerless to prevent their depredations.

A gun will be of great service, destroying a few and frightening many. Bullfinches are also very destructive, and unless checked will clear a quarter in a short time. Those who can afford to erect a permanent cover in the way of galvanised wire netting, using a three-quarter inch mesh, with strong poles as supports, placing the netting at a height of 6 feet from the soil, will find it most advantageous. It may not be thought necessary to cover the top with wire, as nets may be used, but wire is preferable and not expensive.—W.

#### PEACH BUDS DROPPING.

I AM unable to agree with Mr. Douglas (p. 193) that the cause of bud-dropping is partially due to imperfectly developed and badly ripened wood, loss of leaves by insect pests (that is neglect whilst in active growth), and over-dry borders in winter. If I remember aright, Mr. Crump treated on this subject a year or two ago, and several interesting notes appeared from good growers who would soon have remedied the evil if bud-dropping was caused by the agencies described. A few seasons ago, being a sufferer from the same, I naturally read Mr. Crump's note with interest, and was glad to see he did not put down the cause to the evils described in Mr. Douglas's note. I believe such causes to be hereditary, as I notice there is more trouble with some of the newer American varieties than others. Another cause, and one I plead guilty to, is keeping our Peach houses too close at a season full exposure is necessary. Many gardeners take advantage of the leaves being cleared from their early trees to house Chrysanthemums, and the house is not treated like a fruit house at rest, but more care is bestowed on the temporary occupants, to the disadvantage of the fruit trees, and at a time every bit of air and moisture should be admitted. I again refer to the first point, badly ripened wood, and there was little fault to find with the wood last spring, the previous season being all one could wish in this respect, and yet the buds dropped. Then Mr. Douglas may say it was because the trees lost their leaves prematurely owing to the pests he named. Such was not my case; everywhere the wood was thin and, of course, fully exposed, and with early forced trees in such a season as 1893 there was little need of artificial heat to ripen the wood. With later trees it may be necessary, but so far I have failed to see any bud-dropping in their case. I never fear the second or third houses; it is only the earliest. Others may have had a different experience, but such is mine. I now come to dry borders. We have been told dry borders were the cause of bud-dropping for so many years. I am inclined to think we have in most instances taken good care to be on the right side; indeed, I know one man who always empties his tanks fortnightly, having a regular supply of water, after being told the cause of failure or dropping was through dryness, and still they drop; hence my opinion as to some kinds being worse than others. I am inclined to think that gentle forcing is as great a preventive as giving so much water. We have the same trees in later houses with same treatment and they do not drop at all. These American kinds bloom very erratically, I admit, and my advice is to force slow, and in the case of kinds like Early Alexander to grow it sparingly for hard forcing, as with well-ripened wood and clean foliage (the wood laid in thinly)—indeed, one cannot help doing this, as there was no need of dis-budding—and copious supplies of water, we failed to prevent bud-dropping, and, being so annoyed, I as a last resource got rid of the kinds which dropped. This season the young trees have not lost any buds, the varieties being Early Grosse Mignonne (this must not be confounded with Grosse Mignonne), Hale's Early is free of dropping, and Dymond, with older kinds. I specially name Grosse Mignonne, as there are some bad varieties of this good Peach, the one named forcing freely. I am at one with Mr. Douglas in his note with regard to other points of culture, but I am loth to admit blame for bud-dropping, having tried all

the remedies he advises, and others being in the same state, we do not like to admit, although he wishes us to do so, that we bring the trouble on ourselves.—PEACH GROWER.

—Surely Mr. J. Douglas (p. 193) cannot be in earnest in the opinion expressed by him with regard to the cause and remedy for bud-dropping in Peach trees. If so, he certainly cannot have grown the early American varieties Alexander and Waterloo, or he would not so easily have found a perfect remedy. Mr. Douglas gives as reasons for the failing, imperfectly developed and badly-ripened wood, owing to the premature destruction of the leaves by red spider, aphid, or mildew, aggravated by lack of heat after the fruit is gathered. We had trees of both these sorts in the early house and one of Alexander in a successional house, and in each instance bud-dropping has been an annual source of trouble, although not subject to the attack of any of the diseases mentioned in Mr. Douglas's note. Bad wood ripening certainly ought not to be known in trees which perfect their crop early in May, especially where ample ventilation and fire-heat are provided and in structures glazed with large squares of clear glass, and yet under these conditions Alexander was such an offender this season as to merit its dismissal from its position which it has now occupied some five or six years, to be replaced with another which it is hoped will prove a more reliable sort. The two trees simply changed places from a cold unheated house to the early one, and *vice versa*. Here they will have an opportunity of getting inured and established for bearing next year. In our early house there are Early Beatrice, Grosse Mignonne, Bellegarde, and Dunmore Peaches, Lord Napier, Early Rivers, and Elruge Nectarines, and in none of these are there any symptoms of loss through premature bud-dropping, but, on the contrary, they require severe thinning of the unexpanded buds to relieve the trees of the strain. If bad wood ripening accounts for such failings as noted in the American sorts, why is it English varieties are not affected by it when subject to exactly the same treatment in every detail? Mr. Douglas assumes that it is not difficult to apply a remedy, but I am certain many growers besides myself would be grateful to him if he would furnish a permanent remedy for such a troublesome failing. It cannot be other than regretted that such desirable Peaches as the two offending sorts named should be given to such a deceptive trait, because they are so fine, handsomely coloured and early, but in early Peach forcing where these are depended on there is sometimes great disappointment and loss experienced at the flowering period. Quite recently this subject was exhaustively dealt with by your able correspondent "W. I.," and his experience gained under a rather extensive trial might be taken as conclusive and thoroughly trustworthy. My experience exactly coincides with his in the failure of these early Peaches to retain their buds. Aphides, red spider, and mildew were unknown to our trees last season, and they neither lacked moisture at the root nor attention to thinning out the bearing wood as soon as the crop was gathered, yet in spite of all this failure as recorded was our only return. In my opinion it cannot be other than a constitutional weakness, and one which apparently they do not overcome with age and acclimatisation—at least as forcing varieties. Outdoors no such trouble is experienced, nor do I think it will give much anxiety in cold houses, but as I have not yet proved them under the latter course of treatment I cannot speak positively, but I hope to do so in the course of a year or two, as both are now included in the cool house selection.—WILTSHIRE GARDENER.

**Strawberry Scarlet Queen.**—I was pleased to see the note on the above on page 216. It is one of the new varieties we have had very little information about, and "J. C.'s" commendation at this season is opportune, as everyone who forces is anxious to know what merits these new kinds possess before going largely into their culture. I am of the same opinion as "J. C." as regards earli-

ness, and when forced it is much superior to Noble; and, considering it is a seedling from Noble, with King of the Earlies as the male parent, one may expect good flavour, as King of the Earlies is noted for that quality, but is too small when forced to be much of a favourite. "J. C." describes it well when he states, as regards size, it is smaller than Noble, but it is valuable as a free setter and for its good clean growth. I can testify to its good eating qualities when hard forced, and I should say it will make a favourite market variety. Last season I grew it for the first time and was much pleased with its bright vermilion-scarlet fruit, and being a firm berry it may be packed for long distances, as it travels grandly. Its rich, Queen-like flavour should make it valuable where quality and not mere size are considered.—W. S. H.

**Raspberries.**—No time should be lost in pruning old plantations and placing the canes in position for fruiting. Newly-planted canes do best pruned to within 6 inches of the soil. I advise

*Vitis heterophylla humulifolia.* (See page 250.)

removal of the old canes as soon as the fruit is gathered, but if neglected no time should be lost in thinning, leaving from three to five canes to a stool. It is also a good plan to cut down the fruiting canes to a height of 3 feet or 4 feet, as if strong and not too long very little support is needed. After the canes have been tied a good mulch of decayed manure should be placed along the rows or directly over the roots. In gardens where Raspberries do not thrive it is well to make new plantations more frequently and feed more. Autumn fruiterers should be cut down and manured freely and the new growth kept thinned.—B. M.

**Strawberries.**—I never saw the plants look so bad as they do at the present time, the leaves being quite destroyed as well as many surface roots. Though the crowns of strong plants are uninjured,

the loss of top or leaf growth will cause a later growth. The ground should be cleaned between the plants and on poor land a dressing of soot, guano or decayed manure should be lightly stirred in. Previous to this the plants should be well trodden round, as the frost will have lifted them out of the ground. In giving manure either in a liquid or other state, it is well to keep it free of the crowns. In the case of newly-formed plantations only a surface hoeing is necessary, as the firmer the root-hold the plants have of the soil the better they bear. Plants that have been wintered in rows close together for spring planting should now be set out in their permanent quarters in deeply-dug, well-enriched soil, planting firmly and giving strong-growing varieties more space, as it is an easy matter to crop between this season with dwarf growing vegetables.—G. WYTHES.

#### STATE OF APPLE TREES.

OWING to the long spell of wintry weather very much of the time annually spent upon the fruit trees will have of necessity to be considerably curtailed. If this results in the neglect of pruning wall trees, then I have nothing but regret to express, especially if it be the growths on the main branches of Apples, Apricots, Cherries, Pears and Plums that are allowed to go untouched. Of what use is half the walls in the country, seeing that already the spurs on the trees against these stand out to a distance of 9 inches or more? If, on the other hand, shortness of time leads to the neglect—or what is felt to be such—of pruning trees, notably Apples and Pears, quite in the open, there is every likelihood of this turning out advantageously rather than otherwise. Lately I have critically inspected hundreds of garden trees, and, I trust, have done good work in the direction of preventing so free a use of the knife as formerly. In innumerable cases trees are planted in good garden soil previously only devoted to vegetables, and which are still to be principally cropped with these. The Apple or other fruit trees are not to occupy much room—in fact, are to be fruited *à la Rivers*, without, however, adopting the practice of annually or biennially lifting; and the owners are not a little disappointed with the result. Unless the trees, or bushes, as these may be termed, become stunted from the first, the crops of fruit are very light indeed, while those that grow strongly give a very plentiful crop of branches every season.

So very stout and coarse do these much-pruned trees become, that it is doubtful if severe root-pruning would do more than throw them into a stunted, half-dead state; whereas a different method of pruning would bring them into a most productive state within two years of the change being carried out. At the present time there are so many instances of good results following upon what, in very many cases, was thought to be a neglect on the part of the pruner, that the lesson ought not to be forgotten. Wherever strong growths formed during 1893 were left their full full length, these are now bristling with fruit buds. So well did the wood mature, that growths exceptionally stout and long and not crowded promise soon to be wreathed in flower; and, as a matter of fact, I never saw freely-grown Apple trees in a more promising state. Instead, therefore, of annually backing off all the young growths of garden trees, the better plan would be to freely thin out and leave the rest to their full length. This may mean a considerable increase in the size of the trees, but what of that? Either they are worth this extra room, or they ought to be rooted out altogether. Dotting them about highly cultivated ground was a mistake in the first instance,

but when trees can be so quickly brought into a free-bearing state, they must prove far more profitable than vegetables, and it is the latter that should make way for the trees, and not the trees for the vegetables. Latterly I have repeatedly pointed out to amateurs and cottagers how unwise they are to cut and hack about their trees just because they happen to overlap some of their vegetable ground. By all means thin out crowded trees, but think twice before starting upon wholesale lopping.

Among the coal miners in this district are some hard-working, painstaking men who take a particular pride in their gardens. Not having sufficient confidence in their own ability to prune bush or low Apple trees generally, they engage the services of a so-called "experienced pruner." I call him a "tree spoiler," and there are far too many of this class of men in existence. When they come to a tree they are afraid to prune very severely; they have not the sense to thin out where necessary and leave the rest of the growths to their full length, nor will they freely cut back a newly-planted tree. What they do is to merely top the growths and leave them, this being far worse than no pruning at all. A topped growth breaks near the cut ends, and very frequently the lower half or more fails to push either a fruit or wood bud, remaining quite naked for the rest of its life. Either these growths should be cut back hard enough to cause a strong back break of shoots, with perhaps an occasional fruit bud or spur, or else not cut at all. The former plan is desirable when the foundation of a tree has yet to be laid, but when fruit is the chief desideratum, then allow a natural distribution of sap and a natural break, this meaning fruit buds in quantity. Pears, in spite of the heavy crops produced last season, would, but for the birds, have flowered freely in many gardens, but as yet the Apple buds are quite safe, and if we only experience a favourable spring, abundance of Apples should be forthcoming. It is only fair to add that the pruned trees also promise well, but more naturally grown trees are particularly promising, and, it is almost needless to say, will produce, weather permitting, much the heaviest crops of fine fruit. W. IGGULDEN.

Somersct.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

APRIL 9.

THERE was a considerable increase in the amount of tabling at this meeting, but Orchids were again the most attractive feature, although not so many certificates were awarded. From the Burford Lodge collection came a huge specimen of *Cattleya Lawrenceana* in the finest possible condition, a notable example of high-class cultivation. Several fine forms of *Odontoglossum* were to be seen, especially in varieties of *O. triumphans*, that to which a first-class certificate was awarded being in every way deserving of that distinction. *Miltonia Bleuana nobilior* was also shown well. *Cattleya Schroderae* was likewise worthy of note, two excellent specimens of this charming variety coming from St. Albans, from whence was sent a most vigorous example of *Phaius Sanderianus*. Several hybrids of Veitchian origin were present, *Laelia Latona* and *Laelio-Cattleya Pallas superba* being very fine. Several botanical curiosities were sent from the Tring Park collection, of which note will be found. A few splendid forms of *Amaryllis* were sent from Chelsea, and others from Holloway, from whence also came *Clivias* of the best kinds. One of the features of the meeting was undoubtedly the many choice and particularly fine varieties of the *Anthurium*, forms of *A. Scherzerianum* and *A. Andreanum*, in which was likewise evinced the best possible culture. These comprised plants as well as cut spathes. Cut Roses from the point of popularity and attractiveness were particularly good, those

from Colchester being the finer exhibit, but many blooms in both stands were fully up to the exhibition standard. Violets as fine as one could wish, with delightful fragrance, were sent from Swanley, whilst from Cheshunt and Tottenham came hardy herbaceous and alpine flowers in the best varieties. A good collection of *Dracanas* of the newer kinds was staged. What, however, in all probability created the most interest was the seven fine plants in profuse flower, one mass of rich orange colour, of *Streptosolen Jamesoni*, from Mr. Bennett Poë, finer examples than which have never before been seen. Daffodils were to be seen in the best varieties—new and otherwise. *Beaumontia grandiflora* was again shown from Panshanger, where it is so well grown. A thoroughly representative collection of vegetables in season, forced and otherwise, came from Syon, from whence also were sent highly-coloured *La Grosse Sucrée* Strawberries; otherwise there was but little for the fruit and vegetable committee to examine.

### Orchid Committee.

A first-class certificate was given to—

*ODONTOGLOSSUM TRIUMPHANS* LIONEL CRAWSHAY, which in the opinion of many was considered to be the finest variety yet seen of this well-known *Odontoglossum*. It has particularly broad sepals and petals, almost twice the width of ordinary forms, the ground colour of old gold being relieved with dark Oak-coloured blotches, the entire flower of fine form and substance and the growth dwarf and compact. From Mr. De Barri Crawshay, Rosefield, Sevenoaks.

Awards of merit were given to—

*LAELIA FLAVA* VAR. *AURANTIACA*, an intensely rich marked form of this Brazilian species, with deep orange or cinnabar-coloured flowers borne in a cluster at the top of a slender spike as in the case of the type, each bloom about 2 inches across, the spike in question having nine such blooms. From Lord Rothschild, Tring Park, Tring

*ODONTOGLOSSUM CRISPUM* CATHERINE, reported to be a good form, but not *en evidence*, having, it was stated, been removed at or soon after the rising of the committee. No description can thus be given. From Mr. F. Hardy, Ashton-on-Mersey.

Botanical certificates were awarded to *Masdevallia ludibunda*, quite a miniature species of botanical interest possibly, but of no particular beauty. From the Royal Botanic Gardens, Glasnevin. *Bulbophyllum nigropetalum*, a singular-looking species with dark-coloured flowers, was also given a botanical certificate. From Messrs. Lewis and Co., Southgate.

Sir Trevor Lawrence sent a grand specimen plant of *Cattleya Lawrenceana* bearing about one dozen spikes, the finest of which had as many as eleven flowers fully developed, each spike forming quite a bouquet of bloom; the variety also was a good one and of deep colour (award silver Flora medal).

Messrs. J. Veitch and Sons had a choice selection of their own hybrids and of species from various genera, including another very fine example of *Cymbidium eburneo-Lowianum*, which one does not tire of seeing. The plant in question was a very vigorous one, bearing two fine spikes of large flowers in their best condition. *Laelia Latona* (*L. purpurata* × *L. cinnabarina*), with rich orange-coloured flowers, a choice hybrid; *Cypripedium Cleola* (*C. Boissierianum* × *C. Sehlmi album*), which might appropriately be called *C. Sedeni album*, its flowers being much in the way of the last named hybrid, save in colour; *Dendrobium atro-violaceum* in good character, *Cattleya Schroderae*, a fine form with broad petals and a dark golden blotch on the lip; *Odontoglossum Ruckerianum*, of which two distinct varieties were shown, one of these bearing a stout branching spike; *Angraecum fastuosum*, a charming dwarf species with the purest of white flowers, nestling close to the foliage; *Cattleya Trianae delicata*, a very handsome form, slightly flushed in the sepals and petals, with the lip similarly tinted and finely fringed, the deep gol-

den blotch being well displayed. *Odontoglossum crispum* with *O. Roezli* (*Miltenia*) were also included. *Masdevallia ignea*, of which a profusely flowered plant was to be seen; *Cypripedium caudatum* (*Luxembourg var.*), with a stout tall spike bearing fine blooms, in the sepals of which there was apparent a deep golden yellow marking towards the points; and *C. macrobilum*, with two large blooms, were also shown. *Dendrobium Alcippe*, with dark purplish tinted flowers; *Odontoglossum Rossi majus*, a large form, with finely marked blooms; *O. Roezli album*, very pure; *O. Pescatorei*, a pure white form quite devoid of spots, very delicate and beautiful, the plant bearing a splendid spike; *Dendrobium Farmeri roseum*, prettily tinted; *Cattleya Lawrenceana*, *Cypripedium Winnianum* (*C. Druryi* × *C. villosum*), with the form of the former and more of the colour of the latter parent; *C. obscurum*, a hybrid showing some affinity to *C. Crossianum*; also *C. Argus* and *Dendrobium crassinode*, well flowered, with a small example of *D. Hildebrandi*, a pretty, but not a showy species, were also sent (silver Banksian medal).

Messrs. F. Sander and Co. put up a very meritorious and effective group comprising *Dendrobium Brymerianum* with particularly fine flowers, having the papillose fringe in excellent character; *D. dioxanthum*, pale golden yellow, rather small, but quite distinct; *D. Phalenopsis Schroderianum*, of which two unusually stout and vigorous plants were shown, each bearing several spikes in various stages upon the imported bulbs, these in one case measuring 2 feet 6 inches in length with the ends of the old spikes in numbers upon each; and *Celoglyne lentiginosa*, in the way of *C. barbata*, but more vigorous. *Cattleya Schroderae*, of which two splendid examples, quite specimens, were exhibited, one, growing upon a raft, having fourteen blooms, and another in a pot a larger number still; these two plants displayed the beauties of this delicately tinted *Cattleya* to perfection; *Dendrobium Auguste Victoria*, one of the tall-growing species, having bulbs 5 feet long with spikes nearly 2 feet in length and nearly erect, each spike having a profusion of small white flowers (as many as thirty) of singular beauty; *D. amboinense*, very singular and pretty; *Oncidium Rogersi* in its characteristic rich colour; *Eulophiella Elizabethae* with five spikes, a very healthy plant; *Lycaste Skinneri* in its best forms and of deep tints; *Spathoglottis aurea*, a stout example, also *S. plicata* with deep lilac-purple flowers, quite a contrast to the foregoing; *Odontoglossum crispum*, a delicate tinted form, suffused with purple, but void of spots in a marked degree, the spike a fine one; *O. nevadense* and *O. triumphans*, each in good character, were also shown; *Phaius Sanderianus* was represented by a most vigorous example bearing one strong spike more than 6 feet in height, with only the first few flowers as yet expanded. This is a distinctly noble species, having dark lustrous brown sepals and petals, with the lip at first white, turning with age to a pale golden tint. *Cyrtopodium Woodfordi* had a spike of greenish flowers, the spike nearly as long as in the preceding (silver Banksian medal).

Mr. Pitt, Stamford Hill, sent a well-flowered group, comprising two good examples of *Vanda suavis*, each with two strong spikes; *Angraecum Sanderianum*, *A. sesquipedale*, the latter with fine flowers, very pure in colour; *Odontoglossum Roezli* and its white variety; *O. crispum*, deep in colour; *Laelia harpophylla* with six spikes; *Cymbidium eburneum* in good order; *Cypripedium Chamberlainianum* and *Dendrobium thyrsoiflorum*, in all a pretty group (silver Banksian medal).

Messrs. Lewis and Co., Southgate, sent a good assortment well arranged, comprising a dark form of *Odontoglossum triumphans*, a good variety of *O. hystrix*, *Cymbidium Lowianum* (*Southgate var.*), with brighter sepals and petals; *Trichopilia suavis*, with very large and finely-marked flowers; *Masdevallia Houtteana*, in profuse flower and of dark colour; *Odontoglossum laeve superbum*, with dark sepals and petals and a lilac tinted lip; *O. Andersonianum album*; *Dendrobium Brymeri-*

anum, good; and *Cattleya Trianae*, in capital variety (silver Banksian medal).

From Baron Schröder came the original and true form of *Cattleya Lawrenceana*, very rich in colour, notably the lip; also another and much paler variety, pale mauve in colour, with white marbling and an entire absence of the purplish crimson on the lip; and yet another—*C. Lawrenceana Vinckii*, better defined as *violacea*, it having pale violet-tinted sepals and petals and a dark, clouded violet blotch on the labellum; also a vigorous little plant of *Dendrobium Cybele* (*D. Findlayanum* × *D. nobile*), a superb hybrid of the first rank, the lip of which is strikingly fine; and a three-branched spike of *Odontoglossum Ruckerianum* of deep colour. Mr. Statter had *Laelio-Cattleya Pallas superba* (*Laelia crispa* × *Cattleya Dowiana*), with blush sepals and petals, and an extra large elongated lip of deep violet-purple, the golden veins, so characteristic of *C. Dowiana*, being greatly subdued; *Cypripedium selligerum atro-rubens*, a very dark form of sturdy growth, bearing two spikes; *Cattleya Schröderae splendens*, with a deeper tint of rosy pink on the lip, setting off the golden blotch on same to good advantage. A good variety of *Cattleya Mendeli* was also to be seen here. From Mr. De B. Crawshaw came *Odontoglossum crispum* var. with pure white sepals and petals and spots and blotches of the palest chocolate. *O. gloriosum* (Rcsefield variety) also came from this source. Mr. F. Hardy showed *Odontoglossum polyxanthum* (Hardy's var.), a distinct form with larger flowers, well marked, and of extra size. From Lord Rothschild's collection was sent a *Cypripedium* (nat. hybr.) having a decided relationship to *C. Chamberlainianum*, with the same peculiar twists in the petals, the lip being more wedge-shaped and the dorsal sepal with less green in it; presumably it is a form of the species named. Sir Trevor Lawrence staged a fine example of *Miltonia Bleuana nobilior* with extra large flower the size of those of *Miltonia vexillaria*, with much of the character of those of *M. Roezlii*. *O. aspersum violaceum* came from the same source; also *Masdevallia leontoglossa*, quite a dwarf species. From the same collection was sent *Eulophiella Elizabethae*, bearing a good spike; also *Cypripedium Rothschildianum*, with three grand blooms on the one spike, and the pretty hybrid *Epidendrum Endresio-Wallisii*. From the Royal Botanic Gardens, Glasnevin, were sent *Phaius assamicus* and other Orchids. Messrs. Drover, Fareham, sent *Cattleya Trianae* Princess Beatrice, with large, somewhat loose flowers; also a small-flowered plant of the type. Mr. Raphael, Castle Hill, Englefield Green, had the finest spike of *Eulophiella Elizabethae* in the show, with twenty nine flowers and buds. A grand example of *Cattleya guttata* Prinzi came from Tring Park. This form has larger flowers, with a much lighter or creamy ground colour spotted profusely with bright rosy purple, the growth being very vigorous. *Laela crispilabia* was also sent. It is of the *L. flava* type, but with rose-purple flowers. *Dendrobium tetragonum*, an Australian species; *Bulbophyllum nigropetalum viride*, a small, but most interesting species; and *Catasetum* sp. were included here. Major-General E. S. Berkeley, Spetchley, sent a fine young example of *Dendrobium Rolfe roseum*, tipped with bright purple, the lip of a light creamy shade having a trace of purple at the margin. Mr. Smee, The Grange, Carshalton, sent a very fine variety of *Cymbidium Lowianum* called *viride*, bearing a splendid spike of eighteen flowers in which the crimson of the lip, as in the type, is entirely absent. The sepals and petals are of a lighter shade, whilst in the lip is a trace of pale yellow.

#### Floral Committee.

A first-class certificate was awarded to—

*ATACCA CRISTATA*.—A curious plant of weird aspect, having flowers of a shining purple-brown colour, borne in thick clusters at the top of a stout stem, with long thread-like appendages hanging down between them. Its leaves are

large and handsome, and the specimen was a fine one. A good illustration of this singularly quaint plant was given in THE GARDEN of July 17, 1886. It was exhibited by Sir Trevor Lawrence.

Awards of merit were granted to the following:—

*AMARYLLIS DORIS*.—Another of the deep self-coloured kinds which it is satisfactory to note are encouraged. This variety has fine flowers, the petals broad and of a rich crimson colour throughout. From Messrs. J. Veitch and Sons, Chelsea.

*AMARYLLIS CHIMERE*.—This variety shows a marked advance towards scuring an *Amaryllis* with pure white flowers, this colour quite predominating, varied only by a few slight feathered bands of red, the flower of large size. This also came from Messrs. J. Veitch and Sons.

*CLIVIA* RIGHT HON. J. CHAMBERLAIN.—A good variety, with a large truss of brightly coloured flowers. There is a great similarity in all these named forms of *Clivia*, their differences being merely a slight shade of colour or a little extra breadth of petal. Shown by Messrs. J. Laing and Sons, of Forest Hill.

*SAXIFRAGA BOYDI ALBA*.—A charming addition to the early spring-flowering Saxifrages and a gem for the rock garden, in habit identical with *S. Boydi*, of which a coloured plate was given in THE GARDEN, July 5, 1890. Judging from the example shown it blooms profusely. Exhibited by Messrs. Paul and Son, Cheshunt.

*ANTHURUM COMPACTUM*.—A variety with distinct merits, indicated by the name it bears, and shown by Sir Trevor Lawrence.

Miscellaneous exhibits were varied and of a most instructive character, especially the group of hardy flowers from Mr. T. S. Ware, of Tottenham, which comprised all the best spring flowers of the season. *Primulas* were conspicuous in the group; *P. rosea* in large pans, a perfect sheet of bright rosy flowers; *P. denticulata* and its white variety very fine; *P. minima* and *P. Clusiana*, two charming alpine species, both having rosy pink flowers; *P. verticillata* and *P. floribunda*, both with yellow flowers, but unfortunately not quite hardy. Saxifrages were well represented in *S. Bursariana*, *S. sancta*, *S. luteo-purpurea*, *S. Boydi* and *S. oppositifolia* in several forms. *Puschkinia seilloides*, *Narcissus Bulbocodium*, *N. reflexus*, *Iberis saxatilis*, *Anemone vernalis* and *Chionodoxa gigantea* were also noteworthy. A silver Flora medal was awarded. Messrs. Paul and Son, Cheshunt, also showed a choice selection of seasonable flowers. *Saxifraga sancta*, *S. luteo-purpurea*, *S. Boydi* and the white form mentioned above, *Megasea Stracheyi*, *Anemone Pulsatilla*, and *Scopolina Hladnichiana*, which was certificated last year, were most striking. *Mezereon Paul's White* is a good form of this favourite shrub, the shoots being entirely hidden with blossoms of ivory whiteness and strongly scented. *Amaryllises* and *Cannas* were also shown by Messrs. Paul, a silver Banksian medal being awarded. A similar award was given to Messrs. Barr and Son for a large exhibit of cut Daffodils and other hardy flowers, but owing to the backwardness of the season no Daffodils appeared in competition for the special prizes. Trumpet-flowered kinds were well represented in Emperor, Empress, Horsfieldi, tortuosus, princeps, Henry Irving, and Golden Spur. Sir Watkin was fine, also Queen Bess and Leeds Minnie Hume among star flowered varieties. *Anemone fulgens*, *A. Pulsatilla*, *A. blanda*, with *Scillas* and *Chionodoxas* completed the group.

Mr. Frank Cant, of Braiswick Nurseries, Colchester, received a silver-gilt Flora medal for an exhibit of cut Tea Roses, the blooms in size and colour being very fine at this early period. Among the best were *Souvenir d'Elise Vardon*, *Niphetos*, *Mme. Hoste*, *Catherine Mermet*, *Mme. de Watteville*, and *May Rivers*, a recent kind of great promise as here shown, having a fine full flower of pure cream-white colour. Mr. Mount, of Canterbury, also showed Tea Roses, receiving a silver Flora medal.

An effective group of flowering and fine foliaged plants, arranged by Messrs. J. Laing and Sons,

included *Clivias*, *Boronias*, *Begonias*, *Anthuriums*, *Azaleas*, and *Saintpaulia ionantha*, with *Crotons*, *Dracaenas*, *Palms*, and *Ferns*. A silver Flora medal was granted. Sir Trevor Lawrence received a similar award for a large group of *Anthuriums*. *A. Scherzerianum* was shown in many forms, of varied colours, and other fine varieties were *A. burfordiense*, with large spathe of deep crimson colour; *sanguineum*, bright red; *Lawrenceanum* and *Archduke Joseph*, distinct magenta-red. From Mr. J. Bennett Poë, Holmwood, Cheshunt, came some good specimens of *Streptosolen Jamesoni*, figured in THE GARDEN, July 5, 1884, the plants comparatively young, but well grown and profusely bloomed, attracting much notice with their brilliant orange-red flowers which were in large clusters all over the plants. *Calla aurata* from the same source was well shown, the leaves large, mottled with white, the flowers pale yellow, but small. A large group of *Dracaenas* from Messrs. J. Peed and Sons, many varieties, well-grown specimens of medium size and good colour, received a silver Banksian medal, and a similar award was made to Messrs. B. S. Williams and Son, of Holloway, for a group of *Clivias* and *Amaryllises*. Messrs. J. Veitch and Sons, Chelsea, showed *Rhododendron Early Gem*, the plants from the open ground and covered with flowers of a magenta-rose colour. It is one of the earliest flowering kinds, but its flowers soon suffer from frost. *Stachyurus præcox* and *Loropetalum chinense*, both abundant in flower, were also shown by Messrs. Veitch. Branches of the first-named had been cut from bushes in the open air. It is an interesting shrub, flowering so early. Its little bell-shaped flowers are of great substance, borne freely in short racemes along the slender branches. *Loropetalum chinense* had evidently been brought into flower in a cool house, otherwise it is hardy and evergreen, having abundant leafage of a deep green colour and bearing curious flowers, which come on slender lateral branches in clusters. Two large baskets of *Violets*, flowering plants profusely bloomed, the varieties *Marie Louise*, *Neapolitan* and *Swanley White*, came from Mr. Slogrove, gardener to Mrs. Crawford, Gatton, Reigate. Mr. Charles Turner, of Slough, sent plants in flower of the *Tree Carnation* Mrs. Hamlet Riley, a pretty variety with pale pink flowers; and a group of finely-cut specimens of *Arum Lily* came from Mr. A. J. Reid, gardener to Mr. F. C. Carr, Farnham Chase, Slough. *Beaumontia grandiflora* was well shown by Mr. Fitt, also *Habrothamnus scabratus*, a large-flowering raceme of *Cordylone australis* and *Glonera jasmiflora*. *Daphne Blagayana* and *Macleania insignis*, a distinct shrubby plant with long, fleshy flowers of a bright coral-red colour, came from Mr. Moore, Botanic Gardens, Glasnevin. Seedling Daffodils were shown by the Rev. G. H. Engleheart, one pretty hybrid, the result of a cross between *Horsfieldi* and *cyclamineus*, being most distinct, though it had gained nothing in size from its larger parent. The flower was about the same size as that of *cyclamineus*, with a pale sulphur-yellow trumpet and pale cream perianth segments which were not reflexed. A seedling from *Golden Spur* crossed with *cernuus* had a fine flower of the same pale colour as *cernuus*, but with a trumpet unusually large and expanded. Other seedlings were shown by Mrs. Lawrenson, Salerno, Killiney, Dublin, two star-flowered kinds having flowers of fine size, with cups of extra bright orange-yellow colour.

#### Fruit Committee.

There was but a limited number of exhibits before this committee. A collection of twenty-four varieties of vegetables was sent by Mr. G. Wythes, Syon House Gardens, Brentford. They were very tastefully set up, one half being forced, the other from outdoors. Considering the severe weather experienced in February this exhibit was most interesting. The best forced dishes were *Asparagus* cut from permanent beds in the open, very good *Seakale*, a nice dish of *Sharpe's Victor* Potato, *Turnip Early Milan*, *Syon House* and

Ne Plus Ultra dwarf Beans, Syon House and Telegraph Cucumbers, Veitch's Maincrop and Cattell's Eclipse Broccoli. The best green vegetables were Ellam's and Veitch's Earliest of All Cabbage, Veitch's Green Curled and Dwarf Late Kale, Victoria Round Spinach (very good), Witloof Chicory, good Lyon and Musselburgh Leeks, Golden Ball Turnip, very fine Mushrooms and Kales (silver Knightian medal). The same exhibitor sent a very fine lot of La Grosse Sucrée Strawberries, large and of very good colour, receiving a cultural award for the same. He also sent a dish of Victoria Round Spinach as gathered from the open ground to show its hardness. This was desired to be sent to Chiswick for trial to test it with Monstrous Viroflay, a French variety. Mr. Goldsmith, The Gardens, Leonardlee, Horsham, sent a new Apple of great merit, a late variety with firm flesh, brisk flavour, and good either for dessert or cooking. The fruits are medium-sized, with a deep crimson colour on sunny side. The committee wished to see it again.

In the absence of Mr. J. Wood the lecture on "Garden Campanulas" was read by the assistant secretary. The flower was dealt with from a garden point of view, upon which the lecturer enlarged considerably, confining his remarks entirely to the perennial species. Many of them were admirably adapted for the rock garden, but he went further, and suggested as the family was such a large and important one that people should make a Campanula garden. They were quite worthy of being made a special feature of. He had himself tried it on a small scale, and found that the family gave a long season of sustained interest and beauty. Another reason why he would make Campanulas a special feature apart from other things was that, deep blues and purples predominating, the family did not always associate well with other flowers, but the Campanula garden near to, and varied by choice shrubs might be a fine feature. He gave an imaginary description of such a garden, choosing a spot sloping down to water upon the margin of which certain kinds would thrive, briefly reviewing a host of species from the little Campanula caespitosa, that would cover the ground with spreading tufts near the margin, up to the tall growing kinds like *C. macrantha* for the distant parts. He gave instructive advice as to culture and propagation, making special mention of some species, as *C. pulla*, whose roots were almost invisible when the plant was dormant, and any division or increase of stock must take place when the plants were in growth.

#### ROYAL GARDENERS' ORPHAN FUND. ANNUAL DINNER.

THE annual dinner of this fund took place on April 5 in the Whitehall Rooms of the Hotel Metropole. There was a large muster of subscribers, and the tables were splendidly decorated with the choicest flowers kindly sent by several nurserymen for the occasion.

The chair was taken by Mr. H. J. Veitch, and there were also present amongst others Sir Trevor Lawrence, Bart., Messrs. Sherwood, J. H. Veitch, J. G. Veitch, W. Manning, Owen Thomas, J. Assbee, J. Laing, R. Barr, H. J. Jones, H. Turner, G. Wythes, J. Hudson, J. Willard, B. Wynne, G. Gordon, F. Moore, C. Penny, and many others.

After the usual loyal toasts had been proposed, the chairman proposed the toast of the evening, "Success to the Royal Gardeners' Orphan Fund," coupling with it the name of Mr. Sherwood. Mr. Veitch in the course of an able and sympathetic speech said he would like the name of the institution changed to the Royal Jubilee Orphan Fund, as it would give it a distinctive mark as being founded in the Jubilee year, and also would not clash with another body. Those present had a good opportunity of hearing how great has been the progress of the fund, the chairman tracing it from its birth upwards, and he felt sure

everyone was glad to see present that evening on this first occasion at the annual dinner Mr. Chas. Penny, who originated the fund, or threw out the suggestion, in the year 1887. An average of nine children have been elected every year since, and he thought it was good cause for congratulation to know that there were now sixty-four children receiving benefit from the fund, and in certain cases at the age of fourteen an allowance was made to give the orphan a start in the world, which, it need not be said, was of inestimable value. Each year the sum of £832 is paid out for the children, and since the fund started £3237 has been distributed. The chairman said the amount invested partly in consols and partly in Canadian stock was £7587, and at the bankers there was a sum of £8395. He said he thought a reserve fund most essential, which should be increased in the same ratio as the increase in the number of children receiving benefit, and a warm tribute was paid to Mr. A. F. Barron, the honorary secretary, for his painstaking work in the past. Mr. Veitch said it was cause for regret that at the last election half of the candidates the fund could not assist, and he impressed on all gardeners the importance of assisting in its maintenance.

Mr. Sherwood said the thanks of all were due to Mr. Veitch for the great part he took in helping forward all charitable works, and said the Royal Gardeners' Orphan Fund must be kept well before the public, so that they could know of its importance; and one suggestion was made—that of establishing a cot at one of the hospitals. He said a little self-denial would effect this.

Mr. Assbee proposed the toast of "Gardeners and Gardening," and at the outset mentioned that this toast was to have been proposed by Mr. Marshall, who, unfortunately, could not attend through indisposition. Mr. Assbee, in an excellent speech, said the love of flowers was deeply rooted, and in referring to gardeners mentioned those who have recently passed away, instancing, as an example of industry, the late Mr. Thomson, of Clovenfords (who had raised Grape-growing for market to such a pitch of perfection), Mr. Thomas Baines and Mr. W. Dean.

The toast of "The Chairman" was received with much enthusiasm, and Mr. Veitch endeavoured to get as large a sum as possible for the fund in which he evinces so much interest. As a result the sum of £817 19s. 6d. was recorded as having been collected, a few of the larger amounts of which are as follows: H. J. Veitch, 50 guineas; Messrs. J. Veitch and Sons, 25 guineas; Messrs. J. H. Veitch and J. G. Veitch, 10 guineas each; Mr. Sherwood, £35 10s.; Messrs. Rothschild, £73 10s.; a Covent Garden Market table, 50 guineas; a Masonic table, £35 9s.; H. J. Jones and personal friends, £55; Messrs. Wills and Segar's collecting list, £40; Sir Julian Goldsmid, £21; Baron Schroeder, £30; Mr. Hill, Tring Park (collected), £20; Mr. W. Robinson, 15 guineas; Sir Trevor Lawrence, £10 10s.; Mr. Haywood, 10 guineas; Mr. A. Moss, 15 guineas; Mr. Reynolds, Gunnersbury Park (collected), £37 11s., besides others. The reading of these amounts was received with applause.

Mr. H. J. Veitch, in replying to the toast of "The Chairman," said great praise was due to Mr. Barron, who had done so much, and also the stewards. He felt very gratified at the splendid list of subscriptions.

Mr. Barron on rising was received with enthusiasm. He said he intended to do his utmost to assist the continued prosperity of the fund as long as health was spared him.

Other speakers were Mr. Gordon, who replied for the press, Mr. Harry Turner, &c.

We may mention that the decoration of the tables was entrusted to Miss Hudson, who did her work well.

**London Pansy and Violet show.**—We desire to draw the special attention of amateur and professional growers of the Pansy and Viola to the exceptional opportunity which this year's exhibition will afford of spreading the taste for their favourite flower through a much wider circle than

has been possible at other shows held by this society hitherto, inasmuch as that of this year is to be held in the same place and at the same time as the great metropolitan show of the National Rose Society, at which it is well known there is always an enormous crowd of spectators and ardent florists from all parts of the kingdom. To all growers we appeal, being anxious to show the public, in the immediate vicinity of the metropolis (where the Pansy and Viola have been somewhat either neglected or unknown), what a charming display can be made by these lovely flowers when properly treated.

#### MARCH IN SOUTH DEVON.

DURING the month of March the rainfall amounted to 3.11 inches, or 0.12 of an inch above the average for the last seventeen years, and 1.94 inches in excess of the rainfall for March, 1894, the number of days on which rain was recorded being fifteen. The rainfall for the first three months of 1895 has reached 7.22 inches against 7.83 inches during the same period of 1894. Of sunshine, 151 hours 20 minutes were registered, this being 2 hours above the average, but 30 hours 50 minutes less than in the corresponding month of 1894. The month's mean temperature of 43.8° is 1.2° above the average. On twelve nights the thermometer on the grass fell below freezing point, the lowest reading being 25°, or 7° of frost, on the 4th. The wind for twenty-five out of the thirty-one days blew from the S. or W., its highest velocity being reached on the 24th, when 789 miles, or an hourly average of 32.9 miles for the twenty-four hours were recorded.

In the garden the end of the first week saw the Crocuses glowing in patches of purple, gold and white on the brown beds. The chaste white Crocus, with its golden anthers, is decidedly the most attractive both to the eye of the flower-lover and to the appetite of the burly humble-bee who tumble clumsily into the white chalice and anon emerge again laboriously, their banded bodies covered with floury gold dust. The Snowdrops naturalised by the waterside in the wood are hardly flowering so thickly as last year, but perhaps, now that their masses of bloom are less dense, they are more beautiful, since the individual flower-bells show to greater advantage among the trailing Ivy net and shimmering blue of their glaucous leaves.

The Arabis was the first flower to recover after the frost relaxed its iron grip, clumps in the rock-work being white with flowers before the leaves showed signs of green. Now that the Wallflowers are all, or almost all killed, the bees have flocked to the Arabis patches in hundreds and the air has been drowsy with their hum, while now and again, in the mid-day sunshine, hibernated tortoise-shell butterflies opened and shut dilapidated pinions on the snowy petals.

On the 15th the first of the Spring Snowflakes (*Leucojum vernum*) unclosed its buds, and soon a goodly colony were nodding their twin, green-margined bells in the breezes. In one garden that I visited the Summer Snowflake (*L. aestivum*) was also in flower, and I found that this particular clump has always bloomed simultaneously with its naturally earlier congener. *Chionodoxa Lucillie* and *C. sardensis* have made a fine show where they were planted thickly enough and were well established, the latter being decidedly the more effective in colour. *C. Lucillie* exhibits considerable variation when allowed to seed, some of the seedlings showing much more vivid colouring than the ordinary type. I have just seen *C. gigantea* and *C. Alleni* in the garden of a noted grower in the neighbourhood, but was not particularly struck by them. Perhaps after they have become established they will show the improved form that is claimed for them. In this garden the first Narcissus to open was *N. obvallaris* (the Tenby Daffodil) on the 18th, a month later than last year. Then came Van Zion on the 21st, Golden Spur on the 23rd, and cernuus on the 28th, followed by maximus and some of the Ajax section that I collected in Spain on the 29th. With the exception of Stella,

which is showing a prodigal supply of buds, none of the Narcissi seemed destined to make a striking display this year. Some clumps evidently will not throw up more than one or two blooms. This is probably owing to the last summer having been so damp and sunless. The buds of the Christmas Rose (*H. altifolius*), after lying frozen and prone since early in January, thawed in the beginning of the month, and soon becoming erect again opened well and afforded a handful of welcome flowers on the 7th. This Christmas Rose has had an unusually protracted flowering season this winter, the first bloom being cut in October, while it will be well into the middle of April before the last are expanded, a period of nearly six months, during two of which, however, animation was suspended. *Hepaticas* of various colours have been and still are bright, but have suffered, in company with the more tender-leaved *Hellebores*, from the loss of their leaves, which sadly detracted from their appearance. *Crocus Imperati*, with its outer coat of buff, is too seldom seen in gardens, but it is worth growing, while the bright blue of the *Scillas*, that outshines even that of the *Chionodoxas*, is indispensable for banks and beds. The Dog's-tooth Violet (*Erythronium dens-canis*), both the common variety with rosy flowers and the white, are at their best during March, and are invaluable for the rock garden, their curiously mottled leaves adding to their quaint beauty. Another charming March-blooming plant for the same position is *Sisyrinchium grandiflorum*, especially its variety *S. g. album*, the satiny white flowers of which, drooping amidst the thin Rush-like foliage, produce an exceedingly graceful effect. *Primula denticulata* is also well worthy of naturalisation, but where unprotected its foliage has suffered from the late severe weather.

The month had nearly waned ere I saw the picture that struck me as being as near perfection in scheme of colour and form as could well be attained—on a mossy bank a colony of Lent Lilies growing out of a blue carpet of *Anemone apennina*. It was one of the harmonies of Nature—pale yellow and pale blue blended by the blue-green leaves of the Narcissi and the lower tones of the foliage of the *Anemones*. S. W. F.

## NOTES OF THE WEEK.

**Scutellaria Mocciniana** was well shown at the Drill Hall on Tuesday, and attracted much notice by reason of its brilliant colour. The flowers, borne in thick clusters at the tips of the erect shoots, are very numerous and strikingly effective in colour, which is bright scarlet.

**Violets from Ireland.**—I send some Violet blooms—Marie Louise, Cooleronan Hybrid and Comte de Brazza. I think the Cooleronan Hybrid is specially good. All will bear comparison with those noted in last issue of THE GARDEN. —P. K. CORE, *Cooleronan, Ireland*.

\* \* A fine lot, the Cooleronan Hybrid a large and exquisite Violet.—Ed.

**Glonera jasminiflora.**—This, one of a large genus of Brazilian shrubs, was shown on Tuesday by Mr. Fitt from Panshanger Gardens, where many tropical flowering shrubs of great beauty are well grown. It is a pretty thing, having thick clusters of flowers at the top of a leafy stem, the flowers much resembling those of the Honey-suckle in shape and arrangement, in colour pure white.

**Primula Forbesi.**—This species, a recent introduction from China, was shown in fine form at the Drill Hall on Tuesday by Sir Trevor Lawrence. The plants, which filled a large pan, had evidently been grown in a warm house, and they were a perfect mass of graceful blossoms. The slender flower-stems vary in length up to 12 inches, with the flowers in whorls, exceedingly numerous, of a pretty clear lilac colour with orange eye. Among all the *Primulas* there is not another kind

so elegant and profuse in bloom as this. It has short-stalked hairy leaves which form a close tuft.

**Odontoglossum Rossi majus.**—I send you a box of cut blooms of *Odontoglossum Rossi majus*, twelve sprays in variety, and should be pleased to hear what you think of them. I received the plants in February, 1893, just as imported.—W. Eastwood, *The Gardens, Height Side, Newchurch, Manchester*.

\* \* A remarkable collection of forms of this popular Orchid. Some of them are in our opinion deserving of varietal names.—Ed.

**Puschkinia scilloides.**—This gem among early spring flowering bulbs deserves to be more popular. It is one of the prettiest things flowering at the present time, and though nearly allied to the *Scillas*, it is quite distinct, with a characteristic beauty of its own. Its flowers, delicate in colour, bluish white, with a deep blue line down the centre of the petals, are very numerous and borne in a compact head on a stem nearly 6 inches in length.

**Hippeastrum splendens.**—This pretty free-flowering species was noticeable in Mr. Sander's group at the Drill Hall on Tuesday, and it would no doubt be a popular plant if it were more amenable to cultivation. Bulbs when fresh imported flower abundantly, but under cultivation they soon deteriorate. It is a free-flowering species, most of the bulbs shown having three flowering spikes. The flowers are large, graceful in form, and of a light red colour.

**Tulipa Kaufmanniana.**—This, one of the earliest Tulips already in flower, is a pretty species, and so robust in habit that the storms scarcely mar its beauty. Its flower is very large, borne on a stout, erect stalk about 6 inches in height; the petals externally greenish yellow, with a feathered band of red down the centre, and internally pale cream-yellow, deepening into sulphur at the base. The flower both in its fine proportions and delicate colour is most distinct, and the species is a welcome acquisition, whose merits and beauty should be widely known.

**Daffodils.**—A clump of the common double Daffodil here which usually produces a dozen flowers or more shows but one solitary bloom this season, and this at an unusually late date, viz., April 4. As a contrast, on referring to my diary, I find that the same clump came into bloom on March 4 in the year 1884—exactly a month earlier. I daresay this late and impoverished blooming is the result of the uncommonly severe frost last February, which killed outright some well-established plants of *Geranium pratense* var. *album* and *Cyclamen coum* var. *venum* in the same border. —W. M., *Weyford*.

**Salvia Heeri.**—At Broad Oaks, Byfleet, this is grown exceedingly well, and the bright scarlet flowers are borne in great profusion. The variety here is considered a good one; the flowers certainly seem larger and deeper in colour than those of the ordinary type. This may, of course, be owing to the locality or soil being specially suitable. The practice is to strike young plants each year. This is an easy matter, as *Salvias* are not at all difficult to root. They are then planted out in the open garden, and remain there until September, when they are placed into pots in ordinary potting mould. *Salvia Heeri* is naturally branching, but if there be a danger of the plants growing tall, take out the tops to make them bushy. When coming into bloom a little generous treatment in the way of stimulants is found beneficial. —H. S.

**Clematis indivisa lobata.**—I never saw this plant in greater beauty than at The Oaks, Byfleet. One specimen covers the larger portion of the roof of a good sized conservatory, and although the bloom is a little past its best, one can form an idea of its value for the purpose. It is literally covered with masses of white blossoms, which last a considerable time in a cut state. Its cultural requirements are simple. Plant it in a compost of loam, peat and sand, give it a fair root-run, and do not stint the water supply. It

needs little pruning unless it be to keep it within a limited space, for when once established it grows with much freedom. Loose training adds to its beauty, as the branches of bloom hang gracefully at some distance from the glass roof.—H. S.

**Strawberry Royal Sovereign.**—It would be difficult to give too much praise to this as a good forcing variety. A batch brought on under precisely the same conditions as were Laxton's Noble, Vicomtesse Ilricart de Thury, John Ruskin, and Competitor ripened their fruit a week before the Vicomtesse and ten days before Noble, while Ruskin and Competitor are still further in the rear. Royal Sovereign throws its flower-trusses, which are sturdy, well above the foliage in marked distinction to some of the other varieties, especially John Ruskin, which seems a weak grower. Besides being the earliest to ripen fruit, Royal Sovereign is easily bearing the palm in weight of crop, the plants averaging about half a pound's weight of fruit on each. Exceptional berries weigh 1½ ozs. and are particularly taking in appearance, being of a brilliant shining red. For earliness and heavy cropping this Strawberry appears to be *facile princeps*.—S. W. F.

**Carpenteria dying.**—Mr. Ewbank is puzzled about the death of his *Carpenteria*. Perhaps I can help him to explain it. I had the plant first more than a dozen years ago. Since that I have had several plants which have done well, grown into good bushes, flowered well, and one after another they have died. The explanation is that the plant is not a long-lived one, and the same explanation applies to many plants which are supposed to be killed by the frost. Plants die from many other causes than cold, though the cold is generally made to bear the blame of all. As to protection for shrubs, I am sure that the two necessities are to keep in warmth at the roots by mulchings of all sorts and to protect against high winds by screens of almost any description. It is much too early yet to say what is saved and what is lost. I would strongly advise everyone to be very slow about cutting down or pulling up anything yet. Of course, there must be many losses, but there will be some very unexpected gains, like Mr. Ewbank's *Poinciana*. —HENRY N. ELLACOMBE, *Bitton Vicarage, Bristol*.

**William Thomson Memorial Fund.**—We are asked to state that a fund is being raised to commemorate the services to horticulture of the late William Thomson, of Clovenfords, the sum collected to be given to the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund. Should a sufficient sum be obtained, it is proposed to keep a pensioner in perpetuity on the funds of each institution. To enable this to be done a sum of £1250 is necessary; a perpetual pension to the G.R.B.I. requiring £750, and that to the R.G.O.F. £500, the power of electing these pensioners being in the hands of the Royal Caledonian Horticultural Society, Edinburgh. Should a sufficient sum not be obtained for this purpose, it is proposed to divide the amount raised between the two institutions proportionately. It is hoped that a very liberal response will be made not only because of the esteem in which Mr. Thomson was held, but also on account of the object to which the fund is to be devoted. Executive committee for England: H. J. Veitch, chairman; A. F. Barron, Chiswick; Bruce Findlay, Manchester; J. George, Putney; P. E. Kay, Finchley; G. Monro, Covent Garden; G. Norman, Hatfield; F. Sander, St. Albans; J. Smith, Mentmore; R. Tait, Manchester; O. Thomas, Frogmore; H. Williams, Holloway; G. Wythes, Syon House; J. G. Veitch, honorary secretary, R. E. Nursery, 544, King's Road, Chelsea, S.W., to any of whom subscriptions may be sent. It is proposed to close the fund on May 1.

**Names of plants.**—S. N. T.—1, *Lachenalia tricolor*; 2, *Francisca calycina*; 3, *Abutilon vexillarium*; 4, *Chorozeema varium*.—H. A.—1, *Jasminum gracillimum*; 2, cannot undertake to name Roses or any florists' flowers.

No. 1222. SATURDAY, April 20, 1895. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## CHRYSANTHEMUMS.

### NOTES ON RECENTLY INTRODUCED VARIETIES.

To be successful in the cultivation of the popular autumn flower not the least important matter is the study of the ways and peculiarities of each individual kind. Hardly two sorts are alike in constitution, shape of flower and time of blooming. Others again are specially valuable for one mode of culture only, that is, for the growth of gigantic exhibition flowers. The system is, of course, one which has tended more than any other to make the Chrysanthemum what we find it to-day, but still it is after all only one of the many uses for which the plant is so admirably adapted. One would imagine that with the hundreds of new kinds raised each year the wants of all classes of admirers of the flower would be well supplied; but are they? There is still a dull, dingy look among the pink and red-coloured early varieties. Many of the most handsome blooms are obtained on plants which reach an abnormal height, and how prized would be more change, particularly brighter colours, among sorts that naturally bloom late; something that would light up the period of Christmas and after. Late whites are fairly plentiful, but yellows are still scarce; and if the fashion is to be a guide, it seems late Chrysanthemums will be in demand.

**A. H. FEWKES.**—Of the richest yellow, with long, broad, heavy florets. The shape is handsome, while the habit of the plant is very sturdy. This variety came late last season from America, but it certainly promises to be a sort we shall esteem when better known. It is likely to develop fine exhibition blooms as well as prove valuable for the supply of flowers in quantity. For the former purpose choose flower buds which show about the middle of August and treat the plant generously in the way of a large pot and stimulants.

**CECIL WRAY.**—When this variety was successful in obtaining the first-class certificate of the National Chrysanthemum Society it was seen in splendid form, large, spreading, and in every way a fine type of the Japanese. The colour is a bright, clear yellow, florets flat and of great length. Its habit of growth is dwarf and sturdy, the foliage handsome and retained on the stem to the last. I expected to find this variety much in evidence at exhibitions last season, but, curiously, it was among the least shown. Whether this fact was through over-propagation or caused by the uncommonly wet summer it would be hard to say, but I feel sure we shall again see it figuring conspicuously among the choicest exhibition kinds. Its habit, too, as well as the formation of the flowers should make it popular for cutting. Treat this variety well, give it ample pot room, and for large blooms select the early buds.

**COL. CHASE.**—This sort was obtained from the same seed bed as the last named, and when I first saw it I was particularly struck with the chaste and charming colour—a blush cerise shade. The drooping form, too, was very taking. But after cultivating it a season, I have placed it among the second-rate kinds. It grows too tall. The foliage is spare and comparatively unattractive, and its blooms will not come large enough for exhibition. For other purposes there are better and more striking sorts of similar colour. This sort does not require a large pot, and for show one must select early flower-buds.

**COMMANDANT BLUSSET.**—Here we have a splendid kind in every respect. The colour is rich carmine-red. The blooms attain a large size; the florets are long, narrow, and handsomely drooping. It is dwarf in growth, with fine foliage of a dark green colour; somewhat early to bloom. It is a magnificent kind for exhibition, and not less valuable for grouping and for the supply of a quantity of blooms as a bush plant. For exhibition select crown buds, which appear early, give it a pot of 10 inches diameter, and treat it well in the way of stimulating manures, which may, however, be withheld when the blooms show colour. Like most of the highly coloured sorts, it is apt to burn or damp.

**DESDEMONA.**—This is an exceedingly graceful and handsome flower, large, full, with very long, narrow, drooping florets. The colour is a pale rosy pink. Its only fault is a somewhat tall growth, but where the cultivator does not mind this and requires a fine bloom for the show-board, the variety should be added. The early crown buds may be selected. One might try cutting down this variety during June.

**DEUIL DE JULES FERRY.**—I am certain we have not seen this variety at its best. When first sent from France a couple of seasons back it appeared remarkably promising, but owing to a late start last year as well as a sunless season, it was not seen in anything like good form. Its unique shade of violet-rose colour was, however, still there; also the slightly drooping formation and perfectly double flowers. The florets are wide and long. It is of medium height with ample foliage. Being somewhat late, early buds should be secured for exhibition blooms, and as a naturally late-blooming kind, it will prove valuable for cut flowers on account of its striking colour and lasting qualities. Give the variety ample pot room.

**DUCHESS OF WELLINGTON.**—This deep golden yellow flower was seen in good form last year on plants which were rooted late, and consequently had a short season. I expect, therefore, with longer time to develop it will be still finer this year. It is essentially a show flower. The florets are fairly broad and go off to pointed tips. The form is loosely incurving and the bloom forms a full rich mass. The growth of the plant is excellent and the foliage handsome. Secure early buds. Do not employ very large pots, but the plant will respond to stimulating manures.

**DUCHESS OF YORK.**—This novelty was well and consistently exhibited from the middle of October to the end of November, a pretty good test of its merits. It is of medium height and has very fine foliage. Its cultural requirements are simple. Allow ample pot room and, like all the yellow sorts, abundant supplies of water. The colour is particularly pleasing; not deep, but clear. Its formation is of the informal drooping type, graceful and imposing. Large enough to suit the tastes of the exhibitor, it is equally useful for the supply of a large number of flowers on a plant, and is, perhaps, the best new variety seen last autumn.

**GURLANDE.**—This sort is not of the gigantic order, but its deep, full reflexed blooms are remarkable for substance. The colour is white, tinted salmon. It is a good grower, of medium height, and a sort that will be much esteemed when better known.

**HAIRY WONDER.**—Varieties of the hairy-petalled class were never very popular. Mrs. Alpheus Hardy is very beautiful, but most difficult of culture. If, however, these curious types are to be in favour, there is no sort so likely to bring popularity as the one at the head of this note. When at its best the colour is a brown-buff shade, at once distinct and pleasing. The flowers are large, massive and well formed. Its florets point inwards just enough to exhibit the remarkable number of light, hairy spines, which give the blooms a downy appearance. The plant is vigorous, therefore easily grown. Do not select early buds; those that appear in early September will produce the prettier blooms. I should like to see a bush plant of this variety very slightly disbudded. It would certainly form a choice and

taking object. It is well to use 9-inch pots, but the variety must not be overdone with manure.

**LA MEISE** is a well-formed, pure white flower of large size. The habit is somewhat tall. Exhibitors will, however, find it a very useful sort to add to the lists.

**LE RHONE.**—This light soft yellow is a capital sort on account of the sturdiness of its growth. It is good for exhibition, and perhaps more valuable still as an easily cultivated, well-shaped flower for any other purpose. Early-formed buds do not develop well.

**MME. CARNOT.**—Pure white varieties have a most handsome addition in this new kind. The flowers may be obtained of huge size by growing the plant on the orthodox exhibition rules, viz., concentrating all its energy to three blooms. In this case the long narrow florets interlace and build up a graceful mass. Its habit is excellent, and in the matter of foliage it is one of the most striking kinds in existence; good in any style of growth and certain to become popular. Use large pots for this variety, but do not overfeed with manure. White Chrysanthemums are easily ruined by stimulants. Select rather late-formed buds. The blooms from early buds have a thin, spidery appearance.

**MISS MAGGIE BLENKIRON.**—When well grown this is an exceptionally handsome exhibition flower. It is slightly incurved in form and the colour is bronzy yellow; the florets are thick and massive and the growth of the plant remarkably sturdy. Early buds must be chosen. This is not a useful sort for the supply of a quantity of blooms on a plant. The variety requires a long season to do it well; therefore start with a good specimen.

**M. CH. MOLIN.**—This is one of the most striking sorts seen last year. The combination of yellow and bronze is indescribably rich and striking. Its flowers are of reflexed shape, thus showing the upper surface of the florets, large, full, and massive; habit dwarf and the plant of easy culture. Early buds may be had for large blooms, and its qualities are likely to make it valuable as a variety for the supply of flowers in quantity.

**M. GRUYER** is an excellent sort; colour white with a rosy tinge. The blooms grow large, full, and massive. Its form is of the slightly drooping character and the florets are notable for substance. This should prove alike valuable for exhibition and other purposes. The habit of growth is excellent. It will do well with ample pot room and requires generous treatment in the way of fertilisers.

**M. PANKOUCKE.**—This variety is to my thinking the finest yellow Chrysanthemum we have had since the introduction of Sunflower. Its only defect is just a slight want in the brightness of its colour. The blossoms are large and of a true Japanese character—that is, fantastic in arrangement of the florets. The flower stem is stiff, thus holding the bloom firmly, and the growth all that one can desire. For exhibition select early buds and give it ample root space. An amateur's sort, because easily grown and handsome withal.

**MRS. E. G. HILL.**—American introductions are usually late-blooming, but here is a sort at its best in October. The colour is a pleasing shade of lavender, tinted white. It is of most easy culture and not too tall. Blooms grow to the standard of size required by exhibitors, and it is among the most valuable kinds when allowed to develop all its flower-buds. Give this sort a good-sized pot.

**MRS. W. H. LEES.**—Colour white, slightly tinted pink. Late blooms are distinctly pink shaded. It is of immense size and exceedingly graceful in form, having long drooping florets. As a show bloom it is very fine, but its rather tall habit detracts from its value as a variety for more general culture. Early flower-buds should be selected and the ample foliage points to the fact that it requires a good-sized pot and abundance of moisture at the roots.

**MRS. E. S. TRAFFORD.**—A bronzy rose sport from the amateur's typical flower, Wm. Tricker, which cannot be other than welcome. It is among

the easiest to cultivate, has a dwarf habit and good from any buds. Being somewhat early, it is well, however, not to secure those that form before August for the November period. My practice with the type is to restrain the natural vigour by using small pots, that is, not larger than a 9-inch size.

**NIVEUM.**—Any mention of recent Chrysanthemums that did not include this variety would be incomplete. It is for all uses the finest pure white sort we have. Every good quality is possessed by this flower—purity of colour, nice form, substance of petal, erect flower-stem, good habit, and easy to grow. This sort should be cultivated by all. It is safe to say that in a year or two we shall not only see it on every exhibition stand, but the flower markets will demand it in abundance.

**RICHARD DEAN.**—This sort has not yet been seen at its best. I am certain it will become esteemed. It is of large size and very effective in colour—crimson and gold. It has a dwarf, sturdy growth. Employ large pots, select early buds, and give it generous treatment in the way of fertilisers.

**ROSE WYNNE.**—Many persons object to the incurving form of the Japanese. This is one of the type, but most informal in arrangement of the petals, which are long and broad. The bloom builds up to a large size and is useful as an exhibition variety. Colour white, just a little tinted with pink. It is a good grower, of medium height.

**SIR EDWIN T. SMITH.**—This variety possesses a tiding shade of deep rich yellow and the reflexed shaped flowers are massive. Its fault is a weak flower-stem, which makes it unsuited for other purposes besides exhibition blooms. The habit is excellent. Choose buds of early formation.

**SOUVENIR DE PETITE AMIE.**—The growth of this variety is of a very dwarf nature and the foliage handsome. Its flowers are large and of snowy whiteness, of recurved form, thus exhibiting the glossy upper surface. For show, bush plants, grouping, or the supply of a quantity of blooms it will prove an acquisition. Use large pots for this sort, but do not give it much manure in any form. I prefer bones in the soil for white varieties, refraining from the use of fertilisers afterwards.

**WILFRED MARSHALL.**—As a bright yellow show bloom this should be valuable. It is incurved in form, very large and striking. It is easily grown, with a nice dwarf habit of growth and large leaves. Select early buds, for, like most of the incurved Japanese type, it takes a considerable time to develop the blooms.

All the foregoing belong to the Japanese section. Many other sorts seen for the first time last autumn require a year's trial before one can write anything definitely about them. We know by experience that the fact of a variety being awarded a first-class certificate does not of itself prove that such variety is worthy of general cultivation. The blooms only are adjudicated upon. These, perhaps, have been obtained from a weakly plant or one of ungainly growth. They may, again, be produced from skilfully manipulated stems or by mere chance, which may never recur. For example, the magnificent bloom seen of Mrs. C. E. Shea was, I believe, the only one produced. Philadelphia was grown in a climate thousands of miles away. Of Pallanza it is too early to speak, and so on through a list of most promising kinds.

H. S.  
Working.

#### STANDARD OF CHRYSANTHEMUM BLOOMS.

MR. TALLACK and Mr. Douglas do not apparently agree as to the standard that should be adopted in judging Chrysanthemum blooms. Mr. Douglas is alluding to blooms that have been grown mainly to bring out all the points of which they are capable, each variety in its own way. The method

by which this end is attained is to limit the number of blooms upon a plant. Mr. Tallack is evidently alluding chiefly to plants for decoration. This system of culture is better known as the "bush" method of growing the plants. If I am right in my supposition, the two methods afford no room whatever for argument; both are correct in their own particular sphere. Mr. Douglas, I am sure, admires the class of plant which Mr. Tallack favours. The standard "set up by the best judges" of cut blooms embraces an exceedingly wide sphere, so much so, that it would be extremely difficult for even Mr. Tallack to add another. When cut blooms are being judged it matters not whether the plants upon which they grew were 2 feet or 15 feet high. When plants of Chrysanthemums, in groups by themselves, or amongst fine-foliaged plants, are being judged, then the standards alter at once. There "lumpiness," as Mr. Tallack points out, would not carry the award with "the best judges."

When dealing with cut blooms only the considerations kept in view are numerous, embracing such points as size, depth, solidity, breadth of floret, symmetry, freshness, colour, coarseness of floret, contour, well-filled centres, consistency of form with the variety, and lastly difficulty of cultivation. This list is somewhat lengthy, and if Mr. Tallack can say that much relating to the flower is left out, I shall be much surprised. Mr. Tallack appears to find fault with the great depth possessed by some varieties, and appears to think that because of this they lose elegance and grace. I will name but three varieties, viz., Vivand Morel, its sport, Charles Davis, and the newer Duchess of York. Could anything be more beautiful than these? Not only do they possess immense depth of petal, but elegance as well.

Mr. Tallack appears to me to rely too much upon catalogue descriptions. I have long since found these much too misleading generally. He talks of a variety there quoted as being 9 inches in depth. I have never seen a Chrysanthemum bloom of the dimensions quoted. Mr. Tallack names some plants possessing blooms that "had been forced into great depth at the cost of loss of character and beauty." This statement is hardly consistent, as it is not possible to make a naturally thin bloom into a deep one. E. MOLYNEUX.

#### OUTDOOR BLOOMING CHRYSANTHEMUMS.

WITH such an improvement in varieties, outdoor flowering Chrysanthemums are taking a much higher place where blooms for cutting during September, October, and the early part of November are in request. This type of Chrysanthemum consists of varieties with reflexed florets, the bulk of them being small-flowered Japanese kinds. Where the glass accumulation is limited, these early flowering varieties come as a boon to those who have to provide blooms in quantity. There is likewise a clear distinction in the colour of the blooms as grown out of doors compared with those of the same variety developed under glass.

Although Chrysanthemums are regarded as being perfectly hardy plants, they are not so when put to the test of a winter like the past. Some hundreds of plants have succumbed this year to the intense frost. Where the precaution was taken to place a layer of ashes, manure, or leaf mould about the stems of the plants before sharp weather set in, the roots have fairly well withstood the rigours of the winter. Where any doubt exists in the mind of the cultivator that the roots will not remain uninjured in the ground, it is such the best way to lift them after flowering and store them in a cold frame where they can be protected from frost.

About the middle of March, if an increased number of plants should be required, the roots should be divided and planted in boxes in sandy soil. Every single shoot with a root attached will quickly develop into a stocky little plant if the frame be kept close for a time. The more robust the plants are the greater is the prospect of a good crop of bloom. Plants growing at the foot

of south walls will need renovation after such a severe winter. No plants are so good for making up gaps as the old roots or stools that flowered in pots last season. One of the main reasons for this is that so many more growths spring direct from the base than is the case with spring-struck plants of the current year. To furnish a wall thoroughly a good foundation ought to be laid, the growth starting direct from the base. Half-a-dozen shoots from one plant a yard from its neighbour should make a nice display with the additional growths that are the result of various natural breaks. A fairly rich compost is an advantage. A mulching of half-decayed horse manure will do much to conserve moisture in the soil should the months of May and June be hot and dry. Those who have not adopted this form of cultivating Chrysanthemums and beautifying what would otherwise be bare spots, should lose no time in making a start. Where possible to obtain roots of single-flowered varieties I would advise that they be planted, as no type is better suited to this form of outdoor growth than this. Not only do the flowers possess all the points that go to make a graceful combination of colour and form, but they last a long time fresh. E. M.

#### ORCHIDS.

##### CATLEYA GUTTATA AND VARIETIES.

CATLEYA GUTTATA is a very free-growing species, attaining a height of from 2 feet to about 30 inches, the elongated cylindrical bulb being furnished with a pair of coriaceous leaves, each about 8 inches or 9 inches long. This species usually produces its flowers during the winter and spring months, these being borne from five to eight upon a short raceme. The individual blooms measure nearly 4 inches in diameter, the sepals and petals being similar. The flowers in the typical form, which, however, is not often met with at the present time, are of a greenish yellow, spotted with crimson. The side lobes are white on the outer surface, and contrast well with the rich purple of the middle lobe. This fine species was introduced by the Royal Horticultural Society about seventy years ago. It requires treatment similar to that usually given the majority of Cattleyas. One of the most beautiful varieties is

CATLEYA GUTTATA LEOPOLDI, which has bronzy green sepals and petals, with deep purplish spots; the lip is of a bright amethyst-purple, the whole bloom individually smaller than in the typical form. This, however, is made up by the greater number of flowers borne upon the spike, for it often carries a dozen or more upon one peduncle. This variety was introduced about forty-five years ago by a Belgium nurseryman from Santa Caterina. The collector stated that this distinct kind grows naturally more inland, and nowhere near the coast.

C. G. LILACINA.—This is perfectly distinct from the type, especially in the colour; the sepals and petals are pale rose spotted with deep purple, whilst the lip is of a bright magenta crimson. This charming addition first made its appearance in the collection of Sir Trevor Lawrence, Bart., about fifteen or sixteen years ago. It usually flowers somewhat later than other kinds. Another very beautiful and distinct variety is

C. G. PRINZI. This is a very handsome flower; the sepals and petals creamy white, flushed with bright rose and spotted with crimson, whilst the lip is of a deep and bright purple. I recently noticed a fine form of this shown by Mr. Hill, gardener to Lord Rothschild.

These are no doubt the most distinct, but there are others which have received varietal names. WM. HUGH GOWER.

**Dendrobiums from Cheltenham.**—From Mr. J. Cypher, the Exotic Nurseries, Cheltenham,

comes a box of flowers containing a very choice assortment of these beautiful and useful Orchids. Amongst the most noteworthy were the fine *D. nobile* Cooksoni in grand form, *D. nobile* Statterianum, very beautifully coloured; *D. Wardianum* giganteum, flowers of enormous size, measuring upwards of 5 inches across the petals, with bright crimson purplish tips to each segment; also a very beautiful variety of *D. Wardianum* album of the purest white, excepting the pale yellow blotch on the lip. A magnificent form of *D. Leechianum* was also sent, the blooms being of large size and very richly coloured in the throat.—W.

**Cypripedium Harrisianum, nigrum.**—A very fine form of this variety is now in bloom at the Roupell Park Nurseries, Tulse Hill, the flower being identical with that of the typical form, but of a very deep shade of colour. *C. Harrisianum* is remarkable as being the first hybrid raised in our gardens. It is the result of crossing *C. villosum* and *C. barbatum*, and although it was the first one raised, it still takes a foremost place in nearly every collection.—G.

**Cypripedium caudatum** (Wm. Cooper).—This species was introduced about fifty years ago from Peru, where it grows at over 5000 feet elevation. It should be placed with other warm house kinds and given similar treatment. It is a very interesting plant and always attracts attention whenever seen in flower.—W. H. G.

**Angræcum fastuosum.**—This is a very remarkable and distinct little species and one that is seldom seen in bloom. It was introduced about sixteen years ago by Messrs. Sander and Co., of St. Albans, and was also recently exhibited at the Drill Hall by Messrs. Veitch and Sons, of Chelsea. It is a plant of very dwarf growth, producing stems from 1 inch to 2 inches in height. The flowers push up from amongst the leaves in profusion and individually measure about 1½ inches in diameter. These are of the purest white and the long white spur measures 3 inches. It is one of the most distinct species in this genus.—W.

**Masdevallia leontoglossa.**—This very curious and beautiful species recently flowered well in the collection of Sir Trevor Lawrence, Bart. It was introduced by Messrs. Linden, of Brussels, upwards of thirty years ago, but it is still a scarce plant. The flowers are produced on very short peduncles. The perianth tube is pale yellow, spotted above in regular rows and also beneath with deep purple, the sepals having short broad tails about 1 inch in length. These are of a yellowish green ground colour, spotted with very dark purple warts. The small lip is covered with papillæ and is of a rich purple colour.—W. H. G.

**Trichopilia suavis superba.**—A well-flowered specimen of this old favourite was exhibited at the last meeting of the Royal Horticultural Society by Messrs. Lewis and Co., of Southgate, the individual blooms being of fine size and nicely spotted with bright rose. It is now upwards of fifty years since the typical form first made its appearance, and it certainly deserves attention from all lovers of Orchids. It is especially adapted for amateurs with small collections, as it is a plant of very easy culture, free flowering, and possessing a very pleasing powerful fragrance. *Trichopilia suavis* is a native of Costa Rica, where it grows at an altitude of from 6000 feet to 8000 feet. It was first discovered about the year 1848. *Trichopilia* like a good season of rest, and should be potted in fibrous peat and Sphagnum Moss with good drainage, care being taken when repotting that the bulbs are not inserted in the compost, but placed upon an elevated mound above the rim of the pot. The variety here referred to is of exceptional merit, the flowers much larger than in the typical form and very brightly coloured.—G.

**Eulophiella Elizabethæ.**—This remarkable Orchid, which is still a novelty, was represented in the collections of Sir Trevor Lawrence, Bart., and Messrs. Sander and Co., of St. Albans, at the recent meeting of the Royal Horticultural So-

ciety. This plant is sure to become a great favourite amongst Orchid lovers who have sufficient heat at command to grow it, for heat and moisture are its natural requirements. The flowers, pure white on the inner side, deeply coloured on the outer surface, are borne on pedicels and stems of deep purple, thus forming a curious contrast.—W. H. G.

**Lælia Latona.**—This charming hybrid was shown at the Drill Hall on the 9th inst. by Messrs. Veitch and Sons, of Chelsea. It is stated to be a cross between *L. purpurata* and *L. cinnabarina* and produces flowers of an orange-yellow colour, the sepals and petals somewhat narrow and of a uniform shade. The lip is long, undulated at the margin and of a similar ground colour, shaded on the disc, and veined with bright carmine. It is certainly a fine acquisition to this section.—H.

**Dendrobium Rolfeæ roseum.**—Under this name was shown at the Royal Horticultural Society's last meeting a very pretty *Dendrobium* of the noble section, and which was stated to be a natural hybrid. Whether this is a natural hybrid or not, *Dendrobium nobile* predominates, and one would be inclined to believe that this is another of the numerous sports of this variable species. Upon a recent visit to Messrs. Laing and Sons' nurseries at Forest Hill I was shown a very distinct form of *Dendrobium nobile*, which is evidently the same variety as that shown at the Drill Hall.—G.

**Cymbidium Lowianum viride.**—A nice plant of this distinct variety was staged by Mr. Smee, of Carshalton, under this name, and although it is now usually applied to this yellow form of *Lowianum*, the proper name should be *C. Lowianum Mandaianum*, it having been first exhibited by Messrs. Piteher and Manda and described under that name in the horticultural press. The plant referred to carried a nice spike of eighteen blooms, which were of fine size, with clear yellow sepals and petals, the lip, as in the typical form, white, but with a very bright yellow blotch in place of the rich maroon colour. In habit of growth and all other particulars it is identical with the ordinary *C. Lowianum* and makes a very charming companion to that species.—W.

#### ORCHIDS ON BLOCKS.

Of the smaller growing and weakly-rooted species of Orchids there are many that—other conditions being suitable—are better on blocks than in any description of compost. A few also that are usually found difficult to establish may be induced to root upon a piece of teak or other lasting wood, thus giving the plants a start that cannot easily be obtained in any other way. Some may be inclined to argue that as Orchids in the majority of instances grow naturally upon the branches or trunks of trees, therefore blocking is the most suitable, because the most natural, mode of treatment for them. All practical growers, however, will be quick to note the fallacy of this reasoning. Even if we could produce an atmosphere similar to that of the natural habitat of the plants—which, unfortunately, we cannot—the task of watering would be herculean if all the epiphytial section were grown in this way. It is also well known that many Orchids under cultivation produce finer growths and larger flower-spikes than when growing naturally, owing to the moisture-holding and manurial properties of the compost provided. Opinions vary considerably as to the merits of various kinds of wood for Orchid blocks, some choosing teak, others Birch, Oak, Apple, or charred deal. Although to a certain extent a matter of fancy, the teak is probably the best, as it is so long-lasting. Oak newly sawn is certainly unsuitable, although if cut and properly seasoned it serves the purpose well. Cork is freely used for Orchids, and though denounced in some quarters as harbouring insects and fungus, this material will, I believe, be even more used in future than it is at present. I have, personally, had good results by using this material

for many dwarf-growing *Oncidiums*, particularly *O. Papilio*, giving a little Sphagnum Moss and keeping this growing about the plants in summer. *Lælia acuminata*, too, I have recently seen in first-rate order under similar conditions. The great drawback to the general use of blocks is the difficulty that is experienced in transferring the plants to a new piece when the old one decays. It is impossible to do so without checking the plants more or less seriously, so that the advantage of using blocks that last well is obvious. In all cases where practicable it is best to insert the block into a basket or pot as soon as it shows signs of decay, picking out the decayed portions of wood when subsequently repotting; or if a small flat block, it may be cut away all round where there are no roots and the remainder nailed entire to a larger piece, removing the old wood piecemeal as the roots take to the new and securing the plants in position by degrees. *D. Devonianum* when newly imported is an awkward plant to pot, as the long, pendulous stems are not easily supported without burying the eyes at the base, which would be fatal to the plant's well-being. This and similar Orchids may be easily and readily established if wired firmly to suitably sized blocks, the latter being inserted in pots, filling up these with potsherds, charcoal and a little Sphagnum. This will conduce to free root-formation, and the following season the plants may be potted in the ordinary way, or if the roots have taken firm hold of the block, place this in the pot again and treat as described above. The practice which obtains in some gardens of wiring lumps of peat to huge blocks and placing thereon such plants as *Cologyne cristata* cannot be too strongly condemned. The continual watering swells out the peat, the plants are gradually loosened from the blocks, and are always untidy. Wherever wood is used the base of the pseudobulbs or rhizomes must be brought into direct contact with the block, and so firmly fixed that it cannot be moved either way. A little Sphagnum under will do no harm; in fact, it is often necessary, but beyond this nothing is needed, and any plants requiring peat are much better accommodated in other receptacles. In fixing the plants a few thin strips of cork will be found of great assistance, as the wire used must be fine enough to be very pliable, and if tightly drawn, as it must be, it would cut through the rhizomes or pseudobulbs without this protection. Copper wire and tacks or nails should always be used, as in the moist heat of an Orchid house iron soon rusts, galvanised iron being also unsuitable. H. R.

**Odontoglossum læve superbum.**—This fragrant and small-flowered *Odontoglossum* is not much in favour with Orchid growers, its more gorgeous relations being more cared for. A very nice plant carrying a fine spike of many blooms is now flowering with Messrs. Lewis and Co., of Southgate. The sepals and petals are yellow barred and tipped with cinnamon-brown, whilst the lip is of a deep rosy lilac. This plant will often carry three dozen or more flowers upon a spike. I am in receipt of a bloom from C. Kingston under the name of *O. Reichenheimianum*, but this I believe to be synonymous with the above.—W. G.

**Lælia flava** and var. **aurantiaca.**—A spike of this pretty little *Lælia* comes from Chas. Box for a name, who asks for further information respecting its introduction, &c. The flowers to hand are of the typical form (*Lælia flava*), and a nice spike it is with eight fine blooms; these are of a uniform orange-yellow colour. It is a native of Brazil, where it grows at a considerable elevation, and consequently requires cool treatment under cultivation. It is recorded as having first flowered in this country in 1839. The variety *aurantiaca* I noticed at the last show of the Royal Horticultural Society, where it was exhibited by Mr. Hill, gardener to Lord Rothschild, of Tring Park. In this the flowers were similar to those of the type, of good size and of quite a reddish hue.—W. H. G.

## FERNS.

### HARDY FERNS.

In most gardens, large and small, there are places which cannot well be embellished by using flowering plants. Where most things fail, the more vigorous-habited, hardy Ferns will find a happy home. In dark corners or in the shade of trees they will thrive admirably, and once fairly established they will give no further trouble. It is a curious fact that many who do not grudge the labour and expense necessary for the culture of Ferns that demand the shelter of glass make little or no attempt to beautify their garden with our native kinds, which are not inferior to their exotic relatives in beauty of form and nobility of growth. I have a couple of specimens of the common male Fern which some ten years back were small plants with half-a-dozen fronds. At the present time they carry in the season a hundred or more fronds, which attain a height of 4 feet or more. Few exotic Ferns could produce a finer effect, and the majority of them cannot even with the best culture equal this common British species when seen in its best condition. Any fairly good garden soil will suit them, but, of course, they will attain finer proportions in a good compost of loam and leaf-mould. It is quite a mistake to suppose that rockwork or an elevated position of any kind is necessary for the well-being of hardy Ferns generally. Some kinds of lowly growth, such as *Asplenium viride*, *Ceterach officinarum*, and the Holly and Parsley Ferns, must have good drainage, but the robust habited varieties do not need this accommodation, and in a general way do best when the roots are not raised much above the ordinary ground level. Planting them on rockwork, rootwork, or mounds deprives them of the moisture they so much need in the growing season. One of the very finest Ferns is the Royal Fern (*Osmunda regalis*). Nothing can exceed the beauty of this native species when it is in the enjoyment of the conditions that favour its growth. It is a grave error to place this, as is often done, in an elevated position, for it is in its native habitats invariably found where the roots get a liberal supply of moisture even when at rest. In damp woods, swampy places, or by the side of streams or pools of water this Fern attains such noble proportions as to render it one of the finest of the many things in cultivation that are valued for the beauty of their foliage and elegance of growth. The dampest place in the garden should be chosen for this Fern, and if the ground is well prepared and ample space allowed for development, the plants will in due time throw up fronds 6 feet or more in height. The exotic species of Royal Ferns are equally hardy and as worthy of being well cared for. They also delight in moisture, but are apparently longer in coming to their full size. I have several specimens that were planted about twenty years ago, and they are very effective in the summer and autumn months. A plant of *interrupta* was placed on a rootwork at the back of a building which has no guttering, so that it gets, especially in a rainy season, a large amount of moisture. This it evidently enjoys, and I have never seen a finer specimen of this Fern. At the foot of the rootwork is a specimen of *Cypripedium spectabile* which flourishes exceedingly, and which after heavy rains stands for hours in a pool of watery The Lady Fern and its red-stemmed variety are certainly much more worthy of a place in gardens than many of the varieties to which they have given birth, and which are more

curious than beautiful. The same may be said of the Hart's-tongue, the type, to my mind, being infinitely much more ornamental than the majority of its varieties, in many of which the free, vigorous growth natural to this Fern is in a great measure suppressed. There is a richness of verdure in the Hart's-tongue that is particularly attractive, and which few Ferns, hardy or tender, possess in such a high degree. The Hart's-tongue will grow freely in almost any kind of soil, but to see it at its best it should be planted in well-enriched ground. The best specimens I ever had were fed into a high state of luxuriance by a liberal dressing of rotten manure. The fronds were abnormally large and exceptionally rich in colour. There are several varieties of this Fern that are fairly vigorous and not difficult to please. The best are probably *crispum* and *angustifolium*, but, to my mind, even at their best they are not equal to the typical form, which exhibits greater elegance of growth than any of its numerous varieties can lay claim to. Among the *Polystichums* there are some that may be freely used in the manner above indicated. *P. aculeatum* is a noble Fern when fully developed, and the crested form of the male Fern is but little less vigorous and enduring than the common form. In both large and small gardens there can be found room for some of these common, but noble-habited Ferns, which merely require to be well planted and left alone, and require little or no attention for years together. In the wild garden, by the side of water, and under the shade of trees these native Ferns should be freely used. They give variety and add a charm to any garden, large or small.

J. C. B.

### GARDEN ENEMIES.

THE exceptional weather experienced in February, which was responsible for a late season, and consequently one would hope for a more favourable flowering time for our fruit trees, has also had the effect of checking the early appearance of some of the enemies with which we have to contend. They are, however, I fear, not likely to be less numerous on that account; indeed, the few warm days have already brought red spider to the fore, and it is strongly in evidence on the Gooseberry buds. The fact that the many different species of bird and insect that go to make up the great army of garden enemies affect special localities is, perhaps, not sufficiently recognised. An accurate knowledge of this is necessary that the gardener should be on the alert to anticipate and, if possible, avert the attack. I notice a correspondent calls attention on page 176 to the wholesale destruction of buds by bullfinches, and reports to hand from friends tell the same tale. A clean sweep has been made of unprotected Plums, Gooseberries, and Currants. The partiality of the bullfinch for particular localities is apparent when I say that we have not lost a single bud or seen any of the birds all through the season. The damage effected in some localities by these birds has led to the covering up of the bush fruit quarters with close mesh galvanised netting. Would it not be advisable to go in for dwarfier Plums, bush trees that is, and plant them also under cover? This covering is, as a rule, a fixture both at the sides and top. I am inclined, however, to think it would be as well to leave the latter open and cover at certain times of the year with short half-inch mesh fish netting. This could easily be effected by placing a few more posts of the same height as the sides at intervals through the length of the quarter. This netting could be removed after the ripening of the fruit until danger to the buds was anticipated. If we can claim immunity from bullfinches, it is not so in the case of *Aearus telarius*, commonly known as red spider, the second enemy to make its appearance. It is, I think,

always troublesome in light, sandy soils (as may be evinced somewhat later in the year by the skeletonised foliage on the Quick hedges), and where this is so a sharp look out must be kept for its first appearance. March 15 was the first day it was noticed this year, an inspection of the trellis Gooseberries after an hour or two of bright sunshine showing countless thousands of the mite on the tips of the buds. Prompt remedial measures were at once resorted to in the shape of a rather strong dose of an insecticide that was applied with as much force as possible from the nozzle of a syringe, the aim being to give a fine spray to ensure a thorough wetting, and yet use considerable force. It may be noted that when an insecticide is applied at this season before the bursting of the buds, it can be used of greater strength. Make, for instance, two gallons of liquid where three or even four would be necessary in the summer. In the week ending March 23 the whole of the Peach and Nectarine, Plum and Dessert Cherry walls were treated to a similar dose, a little sulphur in this case being incorporated with the liquid. Where walls are old and crevices and nail holes are in evidence it is advisable to apply the mixture with sufficient force that it may find its way into these holes; also every inch of wall and portions of trees should be thoroughly wetted to make sure of the destruction of the enemy. Another garden enemy that is a source of great trouble to many fruit growers is the earwig, and it is unfortunately an enemy which is very difficult to dislodge. Last year, although the Peach, Nectarine, and Apricot trees were dotted all over with Bean and Artichoke stalks long before the fruit showed any sign of ripening, and scores of the insects were blown out each morning, the preventive measures seemed in no way to lessen their numbers, and individual fruits were tapped ere they would give to the pressure of the thumb. I intend to be still earlier in the field this year, and set the traps so soon as any punctures are noticed in the leaves. An idea used to prevail that the numerical strength of the earwigs could be considerably reduced, and the mischief caused by them, so far as wall fruit is concerned, proportionately lessened by clearing away old soil at the foot of the wall to the depth of some 3 inches or 4 inches and substituting fresh, also plastering a breadth of the lower portion of the wall with tar, but as the earwig at an early period of its life is provided with wings, it is probable that any such measures would be of little avail. If any correspondent can suggest a remedy of a drastic nature other than the bean trap above mentioned, he would be conferring a boon on those gardeners who are annually troubled with this very troublesome pest. We were nothing like so much troubled with wasps in 1894 as in the preceding summer, the wet season being no doubt answerable for the diminution of their numbers. A comparative scarcity in the preceding summer does not, however, necessarily mean a scarcity of queens, and with the advent of bright weather a sharp look out must be kept for them, any small sum paid for their bodies being money well spent, especially in those districts that may as a rule be regarded as happy hunting grounds for the wasp. In answer to a query as to the relative capability of outdoor sown *versus* transplanted Onions to resist the attack of the Onion fly, I notice on page 185 a correspondent declares emphatically for transplanted stuff. Doubtless he has good reason for so doing, but can he explain the reason? Is it that the stronger plants are less succulent, that the outer skin, which we know is pierced by the fly, is tougher in the older, larger, stronger plant, and is therefore comparatively safe from attack? In all gardens where the old-fashioned plan of outdoor seed-sowing is still followed, it is advisable to have a supply of fresh soot always on hand, and to give slight dustings of the same two or three times a week until the plants are fairly well advanced. Such dustings are at once a check to the settling of the fly on the grass and a help to the quick growth of the bulb of the Onion.

Claremont.

E. BURRELL.

## RUSHTON.

WE had never heard much of Northamptonshire for its old houses till we happened to go there, and were surprised to see some of the most beautiful houses in England, simple in architecture, dignified in form and charming in colour. Among these stately and beautiful houses was Rushton. The vegetation both of woods and pleasure gardens near helps much. The walls, beautified by time and Lichens, look as perfect as anything can be, more so than the much-talked-of French chateaux, which are very hard in effect.

The absence of flower gardening, except of the ordinary kind which leaves the beds bare in winter, prevents such beautiful effects as we might easily have about such old houses by the use of Roses, flowering climbers, and charming

extremities with a handsome Lichen-covered Doric screen. The ground falls gently down to the stream, and there the effects are very picturesque with the rich water-side vegetation and a pretty old bridge. The place is fortunate in having a fine kitchen and fruit garden, the crops in both departments under Mr. Cruickshank's care being excellent. There are also pretty borders of perennials here, which often come in so well in kitchen gardens suitable for them.

## FLOWER GARDEN.

## ON THE SEEDING OF DAFFODILS.

DECEMBER 10.—This is the first season that I have attempted to secure a harvest of Daffodil

the truth, I do not very confidently count on ever seeing Daffodil blooms from these seeds. Still I do not grudge the labour of hybridising, considerable as that labour has been. Every flower hybridised was duly labelled with the names of both parents, and this in itself was no small trouble. But it was interesting work, and I do not begrudge the pains I took even if I never see a flower from my seeds. Familiar as I was before with the more salient points in the various species and varieties, the attempt to cross varieties brought out characteristics that would have been otherwise unknown to me. For instance, I have in former notes remarked on the difficulty of distinguishing *Empress* from a well-grown *Horsfieldi*. I believe that I have now discovered this point of difference at least between them—that *Horsfieldi* if impregnated

Rushton. Engraved for THE GARDEN from a photograph by the late Mr. J. L. Robinson, C.E., Dublin.

evergreen things which are essential in the permanent kind of flower gardening. In very few of these lovely houses are the opportunities they offer for true flower gardening in simple and delightful ways taken advantage of.

Rushton, built mainly of local Weldon stone, is charmingly situated upon a gentle eminence which rises from the Ise, a small stream watering the park. It was commenced during the second half of the fifteenth century by Sir John Tresham, further enlarged by Sir Thomas Tresham, who died in 1605, and finished by the Cockaynes about 1630. The work of the time of Elizabeth and James dominates the design, and the simple masterly treatment makes the house one of the stateliest in the country. It is built round three sides of a quadrangle, the centre facing east and west, the north and south wings running from the main building easterly, connected at their

seed. In former years I have plucked stray pods and burst them open to see the beautiful jet-black and shining grains. But the pods were certainly not plentiful on any variety with the exception of the common *Jonquil*, which bears self-fertilised seed abundantly, and sows itself with very satisfactory results if only the nidus for the seed be at all suitable. Of course there is no object in sowing such self-fertilised seed. New varieties are not likely to be produced from it; an increase by means of offsets is rapid enough to make the tedious process of raising bulbs from seed unnecessary. This year, however, I have diligently cross-fertilised, with the result that I have harvested a large collection of seeds of various sorts. I suppose I shall sow them if I can find time, but as to their ever giving me flowering bulbs, that is quite another question. Five to seven years is a long time to have in prospect, and, to tell

with good pollen will bear seed-pods enclosing sound, plump seed; whereas *Empress* is mostly, if not absolutely sterile. At least, of the many blooms of *Empress* that I treated in various parts of the garden and in various exposures, not one pod came to anything, whilst flowers of *Horsfieldi* when cross-fertilised bore seed in very respectable quantity. The palm for seed-bearing must be given, I think, to *princeps*. It was delightful to me to gather the fat capsules of this Daffodil, fertilised with all sorts of pollen, and squeeze out the beautiful black seed in showers. One capsule of this variety held no fewer than 52 grains, the pollen used in this case being that of *spurius*. And not only is *princeps* a good seed-bearer, but as far I can judge its pollen is very effective, though, as regards powerful and abundant pollen, *maximus* appears to me to come in first. My flowers of this variety, unfortunately, were few in number,

but so abundant is the pollen that one flower goes a long way. Of numerous flowers of Emperor and of Morning Star—a Daffodil very like princeps—fertilised with maximus, I do not think that one failed to set for seed. The pollen also of triandrus seemed to me to be of excellent quality, though here again my flowers were too few in number to enable me to generalise. I cross-fertilised a very considerable number of moschatus with various kinds of pollen of N. minor, Jonquil, Polyanthus gloriosus, and others, but the results were disappointing. The capsules seemed to grow and swell with marvellous vitality, and I looked for a rare lot of seed, but those that perfected seed were not many and the seeds in each capsule that did ripen were few in number. Emperor is a fine seed-bearer, nearly as good as princeps, though each capsule does not contain so many seeds as in the case of princeps. Pallidus præcox var. asturiens also seems to be very fertile, though I should think that the pollen of the delicate sulphur trumpet Daffodils is, generally speaking, weak.

Of course it does not follow, because you impregnate one Daffodil with the pollen of another, that you have thereby secured a hybrid even when the seed sets; the seeds produced may after all be the result of self-fertilisation—that is, unless one grows the Daffodils in pots and removes the anthers before the pollen has become loose, a laborious piece of work which only those could undertake who could give to it unlimited time. But when I compare the small amount of seed produced in former years by the Daffodils in my garden with the abundant return from several varieties this year, I conclude that the cross-fertilisation which I so industriously carried out has been pretty effectual.

The earliest seed to ripen was that of obvallaris, the latest that of Emperor. I have harvested a large amount of seed, but I believe I must have lost more than I gathered. In the first place a storm of snow and wind battered down many stalks that were plumping for seed in quite a promising way. As for staking each head, the labour involved would be too great. A good plan is to tie several neighbouring heads in one bundle, when they will support each other. But besides the amount of seed lost from the battering down of stalks, a good many ripe pods scattered their grains before they could be gathered, and I found that when this happened I could seldom discover the spilt seed on the ground: it had probably been eaten by birds. To prevent loss of seed in this way the best plan is to gather the pods before they are dead ripe.

The following is a list of the combinations from which I obtained seed in greater or less quantity. The first named is, of course, the seed-bearer:—

Albicans × Emperor.  
Emperor × cernuus.  
Emperor × maximus major (?).  
Emperor × poeticus ornatus.  
Emperor × maximus (very prolific).  
Emperor × princeps.  
Emperor × moschatus.  
Horsfieldi × poeticus ornatus.  
Horsfieldi × triandrus.  
Maximus major (?) × Empress.  
Maximus major (?) × ornatus.  
Bicolor Morning Star × maximus.  
Moschatus × obvallaris.  
Moschatus × Jonquil.  
Moschatus × Corbularia citrinus.  
Moschatus × poeticus ornatus.  
Obvallaris × moschatus.  
Obvallaris × Polyanthus N. gloriosus.  
Obvallaris × N. minor.

Pallidus præcox × triandrus (one seed).  
Pallidus præcox asturiens × N. minor.  
Pallidus præcox asturiens × Polyanthus N. gloriosus.  
Pallidus præcox asturiens × Jonquil.  
Princeps × Corbularia citrinus.  
Princeps × pallidus præcox.  
Princeps × spurius (one pod of this cross contained fifty-two seeds).  
Princeps × N. minor.  
Princeps × moschatus.  
Princeps × Leedsii amabilis.  
Princeps × Emperor.  
Spurius × moschatus.

I am sorry that I have not noted all those combinations which failed to set seed. Spurius appears to be a poor seed-bearer, but whether mine failed from an inherent tendency to sterility or because the flower-stalks were a good deal dashed by the wind, I cannot decide. Obvallaris, on the other hand, seems as if it might become the parent of varieties. Maximus is a splendid variety for pollen, but whether this variety readily sets seed I cannot say, my stock being too small to allow of my making experiments to any extent. Want of the necessary leisure prevented me from dealing with any of the poeticus section as seed-bearers. I have marked the variety maximus major with a query, because I do not think there can be any Daffodil with such an atrocious name, but that so named with me is a handsome Daffodil, much resembling maximus in habit of flower and foliage, but bicolor in colour.

Dunedin, N.Z.

A. WILSON.

**Gaillardias.**—Although I have grown these for some years, this is the first winter that I have known them to be affected by frost. With me they have hitherto retained a small amount of leafage through the winter months, but the old stools after the protracted hard frost looked as if they were quite dead. These Gaillardias are very peculiar, for although in my case the crowns and the thick roots are killed and rotten, I find that lower down the roots are already pushing out new growths, so that the existence of the plants is practically ensured. I have not tried, but I believe that the smallest bit of root would, if cared for, form a plant. A year or two ago I transplanted some old roots and the ground remained undisturbed. To my surprise, quite late in the summer a crowd of small Gaillardias came up. In taking up the plants I had broken off some of the smaller roots and these became plants. If we were to experience such winters as the past one it would be necessary to protect slightly, as when the plants are so injured the flowering time is much delayed.—J. C. B.

**Senecio Doronicum.**—Among the earlier flowering of the composites this Senecio is one of the most showy. In height it is scarcely more than 1½ feet when fully grown. In appearance it is neat and compact, and when its orange golden blossoms are fully expanded, it is very attractive. It is by no means so frequently seen as it should be, for at its time of flowering we have not much of its shade of colour in the herbaceous border. The plant gives little trouble to the cultivator and requires no staking or tying when in bloom, it being, in fact, quite self-supporting. Being among the number which flower early in the year, it is better transplanted in early autumn, so as not to imperil its flowering. It may be increased by careful division in autumn, or, if quantity be required, by root cuttings in winter in the usual way.—E. J.

**Marguerite Carnations.**—I sowed the seed of these early in February and find that better results follow than from sowing later. I find the plants succeed much better in pots than in the open, especially if required for flowering in the late autumn and through the winter months. I have to-day (April 6) gathered a nice lot of blooms

from plants raised in February, 1894, and which have given a lot of bloom all through the winter in an ordinary greenhouse. These Marguerite Carnations are valuable in September after the ordinary Carnations are over.—E. M.

**Violet Queen Victoria.**—Those who admire double Violets should give this a trial. It is remarkably rich in colour, and for winter and early spring flowering affords a fine contrast to the Neapolitan, Marie Louise and Comte de Brazza. It would, I think, be difficult to find four Violets better fitted for culture under glass than the above. Queen Victoria has rich green foliage, flowers with as much freedom as the Neapolitan, and I fancy would succeed where the latter cannot be induced to grow with sufficient vigour to allow of the plants producing a good crop of flowers. The great enemy of all the double Violets is red spider. In some gardens where the soil is light it is almost impossible to keep the plants free from this terrible pest. In spite of rich soil, frequent waterings and sprinklings, there comes a time when the enemy gains a foothold and the growth of the plants is at once affected. The only remedy, or rather preventive, that I have found efficacious is shading from very hot sun either with canvas or with Birch sprays laid over the beds.—J. C. B.

## THE ROCK GARDEN.

### IV.

MARCH 28.—Spring at last. Though many pretty flowers bloomed in the rock garden as early as January, their beauty was of short duration, and King Frost held his undisputed reign for many weeks. But after weary waiting, genial sunshine has at last awakened the alpine from their winter sleep, and one by one the gay spring flowers unfold their charming blossoms, which are all the better appreciated for their somewhat late arrival.

Among Saxifrages now in bloom there is perhaps more variety of colour than at any other season. The host of white flowers among the mossy kinds has not yet made its appearance, but there are much choicer gems among the section which flowers earliest of all, and in every well-designed rock garden these should be combined into large groups for early spring effect. The best way of arranging them would undoubtedly be to combine the different colours into groups of varying sizes, so that the colour of each group would blend harmoniously, and here and there be intermingled with the adjoining group. An important point, of course, would be the *tout ensemble*, or connecting the various groups into one grand and effective picture.

Let me suggest the material for this picture of early Saxifrages. The following varieties are all now in full bloom (here in Devonshire), and may be said to be very fit companions for each other: *Saxifraga Burseriana*, *S. apicularis*, *S. oppositifolia*, *S. o. alba*, *S. o. pyrenaica superba*, *S. sancta*.

As all of these make exceedingly neat and compact tufts of evergreen growth, they are also well adapted for forming a carpet on which a few later-flowering things may be displayed to advantage. *Saxifraga Burseriana* does certainly best planted into a slightly sloping crevice which has been filled with gritty calcareous soil and is fully exposed to the sun. In such a position it is flowering most abundantly at the time of writing, not only here in Exeter, but also at Torquay, Newton Abbot, and other places. There is something exquisitely neat about *S. Burseriana* which makes it a picture in itself, and one of the first-class gems for the rock garden. The glaucous cushion of densely-crowded prickly foliage is ornamental even without the

blossoms, but when the flowers appear with their red stem and calyx, the large pure white corolla, and golden yellow anthers, the picture is altogether unique. *Saxifraga apicularis* forms a carpet of the brightest green on which the flowers of a primrose-yellow are most abundantly produced. I find it doing best on ground not quite so slanting as that recommended for *S. Burseriana*. At Exeter it is growing in gritty loam.

The well-known *S. oppositifolia*, with its charming rosy purple flowers, forms a delightful contrast to the primrose colour of *S. apicularis*. In many rock gardens *S. oppositifolia* does not thrive well, but in nine cases out of ten the fault is in the planting. It should invariably be planted on the shady side of a rock without being overshadowed, and I know several in-

(though during less severe winters their flowering season would be much earlier) very few can equal the well-known *Chionodoxa Lucilla*, *Chionodoxa sardensis*, *Scilla sibirica*, and *Scilla sibirica alba*. The bright blue varieties almost equal the colour of the *Gentian*, and are very fit neighbours for the *Saxifrages* just mentioned, which contain no such colour. A most natural and effective way of displaying these bulbs to their best advantage is to scatter them irregularly over patches of soil that have been covered with neat-growing carpeting plants, such as *Antennaria tomentosa*, *Sedum dasyphyllum*, *Sedum pruinaum* and similar kinds. The rich colours of the bulbous flowers show up all the brighter for the duller tints carpeting the ground beneath them.

Several *Cyclamens* are still in bloom this

and *Dondia Epipactis*, with its curious umbel of golden yellow flowers resting on a comparatively large involucre of broad green bracts, presenting a very pretty effect.

Exeter.

F. W. MEYER.

(To be continued.)

#### DORONICUM PLANTAGINEUM HARPUR-CREWE.

THE illustration here given shows the best of a handsome family of hardy spring-flowering plants. There are several fine *Doronicums* growing in gardens, but there are more names than distinct varieties, which leads to some confusion. It is important to know and grow the best of them. The varieties found in gardens can mostly be referred to two species, namely, *D. pardalianches*, which is distinguished by its rounded woolly leaves and tall flower-stems, 3 feet to 4 feet in height, and *D. plantagineum*, with larger flowers on shorter stems and more ovate leaves, resembling those of the Plantain. The variety named Harpur-Crewe originated in the garden of the gentleman whose name it bears, and its great merit is that of continuous blooming. From early spring to late autumn it will maintain an abundant succession of its fine flowers if rightly treated. In common with all the *Doronicums*, it is easily increased by division, which should take place frequently at different times, so as to secure strong batches of young plants succeeding each other in flowering. Besides the brilliant effect it gives in beds and borders, mention must be made of its merits as a cut flower, for which it is useful and lasting. Those who have reserve gardens to supply flowers for the house will find this plant of great service.

A. H.

#### SCHIZOSTYLIS COCCINEA.

FOR the cool greenhouse or conservatory in the early months of autumn this beautiful Crimson Flag—or Kaffir Lily, as it is sometimes called—is among the most useful. Few plants can equal it for brilliant colouring at the time stated when seen in good condition. In a few gardens here and there may be seen a small batch of it in fair condition, with perhaps half-a-dozen or so spikes issuing from an 8-inch pot, and these by no means of the best quality. That so beautiful and useful an autumn-flowering plant should be so generally neglected is a matter for regret. The usual way of treating this plant is to transplant it in clumps, hence the reason of so much useless growth and so very little bloom. Often in one large pot may be found sufficient material for a dozen, supposing it to have been well grown, instead of the indifferent treatment usually accorded it. Just at this season of the year the plant is commencing fresh growth and it is a good time to take it in hand. To do the plant justice and to produce strong-flowering plants that will send forth spikes bearing a dozen to eighteen of its brilliant scarlet blossoms some little cultural treatment is necessary. Where large pots of it exist these should be shaken out when all fear of frost is past, and, selecting the largest-sized plants, transplant them 6 inches apart on a warm south border in soil fairly deep and rich. At planting time if the weather be dry a good watering may be necessary, but afterwards they will take care of themselves. The plant succeeds well in strong, rich loam and in this soil grows vigorously, rarely showing any signs of disease in the leaves. By the autumn the largest plants will have growths as large as a man's thumb, shorter than usual it may be, but sturdy and certain to flower well. The smaller pieces from the spring planting should be pricked off into boxes or into nursery beds to form the batch for another year. Though the plant is comparatively

Flowers of *Doronicum Harpur-Crewe* in a vase. From a photograph sent by Mrs. Wakeman-Newport, Sandbourne, Bewdley.

stances where plants that refused to thrive made excellent progress directly they were transferred to the north side of the rock garden. The white variety (*S. oppositifolia alba*) seems still rather rare, but the improved species, *S. pyrenaica superba*, with its large and handsome flowers, is deservedly popular and is just now at its best. *Saxifraga sancta* is not grown nearly so much as it deserves to be. It forms a delightful contrast to the last-named kind, the colour of its blossoms being a very deep rich golden yellow. It slightly resembles *S. apicularis*, but both its foliage and its flowers are darker than in that variety. At Exeter it covers a stony ledge fully exposed, and is flowering at present most abundantly. I have seen other plants of this species do equally well in a half-shady position, but the flowers would appear later. Of effective bulbous plants flowering this week

week, and so are also many kinds of *Hepaticas* and that charming dark blue *Anemone A. blanda*. As all these prefer a shady or half-shady position, they might well be grouped together. *Hepaticas* and *Cyclamens* often will grow in the shade of trees where other plants refuse to thrive, and their colours vary so much, that quite a picture might be formed of *Hepaticas* alone. There are this week no less than eight distinct varieties blooming together in Exeter: pure white, single and double reds, and single and double blue in various shades, the variety *Hepatica Barlowi*, with its deep blue flowers, being particularly striking.

Among rock garden plants now flowering in a sunny position I may mention *Draba Aizoon*, with its bright yellow flowers; *Megasea Stracheyi*, with its charming white flowers tinged with the slightest touch of delicate pink;

hardy it cannot endure severe frosts, and for autumn flowering should be lifted early, potted, and placed in a cold frame for a few days to encourage new roots. After flowering is completed remove to a pit secure from frost. In spring these plants may be potted into larger pots and plunged in the open in coal ashes. Having kept the plants two seasons in the pots, they will be best shaken out and planted in the open as recommended above. In this way continued vigour may be kept up and its useful spikes of flowers fully repay the labour entailed. E. J.

## TREES AND SHRUBS.

### JAPANESE MAPLES.

A GREAT number of hardy shrubs are brought on under glass and employed for the embellishment of the greenhouse or conservatory during the winter and early spring months, but in nearly every case it is the blossoms which form their most attractive feature, hence the various Japanese Maples stand out almost unique among plants of this class, as their principal beauty consists in the charming foliage. The most of these Japanese Maples are varieties of *Acer palmatum*, more generally known under the specific name of *polymorphum*. They differ from the normal palmate-leaved type in various ways, some having the foliage richly coloured, particularly in *atro-purpureum* and *sanguineum*, while in one form, *roseum marginatum*, the small leaves are all deeply edged with pink. In some, again, the foliage is very finely divided, and amongst this class there are varieties with coloured leaves as well as some forms in which the foliage is green. The habit of the plant, too, varies in the different varieties. When required for indoor decoration they may be grown altogether in pots, and readily lend themselves to this mode of culture. When no longer required for the greenhouse they may be plunged out of doors and allowed to remain there till the autumn, when I prefer to remove them under slight shelter, for though hardy they are when in pots the better for a little protection, for the sake not only of the plants, but also of the pots in which they are growing. These *Acers* are all propagated by grafting on to the typical *A. palmatum*, with which the whole of the varieties readily unite. They are largely grown by the Japanese, who from their desire for singularity are fond of grafting several varieties on to one plant, the result being a curiosity, but to my mind far less pleasing than when each variety forms a specimen by itself. Plants grafted as above described in Japan often make their appearance during the winter in the London auction rooms, being sent from that country in company with Lilies, Tree Peonies, and various other subjects. The *Acers* are, however, as a rule, not a success, for the stocks on which they are grafted are usually old and gnarled, with but few roots; hence they bear the journey so badly that the mortality among them is generally very great, and the living ones by no means realise high prices. They are usually sent tied up in bundles of half-a-dozen or more, with the roots surrounded by Moss, and packed in such a way that they are held securely in position while the air can circulate around the branches. In this way, however, the hard, woody nature of the plants does not enable them to travel like the Tree Peonies, which are of a stouter and more succulent nature. The fact that these Japanese Maples are hardy is to a great extent overlooked by planters, yet they form very beautiful objects in the open ground. So situated, the

palm must, I think, be awarded to those two coloured-leaved varieties *atro-purpureum* and *sanguineum*, which glow with a mass of colour till the leaves drop. The richest tints are furnished by plants fully exposed to the sun, but not where they are parched up during the summer, as these Maples delight in a cool, fairly moist spot, and succeed even in soils of a heavy consistency. T.

### THE WHITE PINE.

WE fear we have from time to time undervalued this tree. Although we have seen it in its native country where its magnificent stature is very striking, a great many places in England never show any fine trees of it. We have lately seen some very fine ones at Cliveden, which makes us think more of its value as one of our really hardy exotic Pines. It is all over Canada, and is, perhaps, one of the finest trees one sees there, especially if one is lucky enough to come across a colony of old trees. We hear a very good account of the way it does in Germany, and perhaps some of our readers can tell us of good plantations of it in various parts of this country. There cannot be any doubt about its hardiness.

The misfortune of this garden planting of conifers is that they are never done in any sensible, thorough woodmanlike way. The pine-tree, with its grafted trees all stuck about like toys, is no good whatever, and even in the best pineta the experiments are vitiated by the large amount of soil given to many of the trees, as at Dropmore, where Mr. Philip Frost gave scores of loads of good loam to the Douglas Fir. This prevents any fair test of the natural conditions of our own country. Deep masses of made ground like this retain moisture so long, that the first test of all, and perhaps the most important as regards coniferous trees, is the power of the tree to do with our rainfall. That is why we see so many garden trees thriving very well for a few years as long as the artificial mass of soil in which they are planted holds out, but when the trees begin to root into the natural soil of the country and to try to put up with our rainfall, we see many of them turning backwards, dying and perishing. Planters should try much more Pines like this in masses, just as they would Larch or Scotch, adapting the tree to the soil as far as possible, but adding no artificial aid whatever; because, as we take it, a tree can be of no use in our woodlands that will not live on the same terms as our Oak, Beech and Scotch Fir, that is to say, give us a good result from the natural soils and conditions of the country. Woods or plantations of the White Pine from that point of view we should like very much to hear something about.

*Spiræa Lindleyana*.—This Himalayan species, so well described on p. 222 of THE GARDEN, is without doubt the best of the whole family of shrubby kinds. The finest example I ever saw was at Orton Hall, Peterborough. Growing there at the back of one of the rock gardens, it reached fully 15 feet high. The semi-drooping panicles of blossom had a charming effect.—E. M.

*Choisya ternata*.—Though this is hardy in many districts of England, in others it needs a certain amount of protection, and where this is the case it is well worth attention for flowering under glass, as it gives but little trouble and will bloom freely. For a structure from which the frost is just excluded during the winter it is very valuable, as a thriving specimen is, from its rich green foliage, decidedly ornamental even when out of bloom. The fact that it is hardy in many parts of the country stands it in good stead for a house in which it is difficult to maintain much

heat during the winter. After flowering it may as soon as all danger from sharp frosts is over be plunged out of doors to remain, till the autumn. About fifteen years ago the Mexican Orange Flower, as the *Choisya* is sometimes called, attracted a good deal of attention as a flowering shrub for the greenhouse, but proving hardy in so many districts it was less grown under glass. The last winter, however, has so severely crippled it, that it is probable (in common with many other so-called hardy evergreens) we shall not see it outdoors so much as formerly, in which case it may be more grown as a greenhouse shrub.—T.

**Furze and the winter.**—The destruction of the common Furze throughout the country must be great, judging by what we see in the southern counties. We grow several kinds of Furze—the Foxbrush and the autumn flowering, or, as it is sometimes called, Irish Furze. They seem to be about equally affected by the frost; that is to say, in many cases dead to the ground, or nearly so. When people talk of the use of the Furze as a fodder plant, its tenderness in hard winters should be taken into account. It is not pleasant to see large masses of this plant dead, and so the simplest way out of it is to put a match to them. After that the man who cuts down the stems finds his work very much easier. We set fire to a mass the other day, and never saw handsomer flames or quicker execution. It was a sunny afternoon, and the flame ran through the mass in six minutes. It is best to do this with Furze, because when it starts from the bottom it breaks all the fresher and better. It is better to chop down the stems after burning. With all its tenderness it is too charming a bush to give up, and we go on sowing our Furze. Near the sea, perhaps, it is not so much injured as in inland places, and its frequency near the sea on the Continent is no doubt the reason why the French call it the "Sea Rush."—*Fitch*.

### THE PONTIC RHODODENDRONS AND THE FROST.

THE Laurels, which are now dead by millions, are not by any means the only frauds among our evergreens. Perhaps, after the Laurel, the most popular shrub with the country gentlemen in England is the Pontic Rhododendron, and no doubt many people think that by using it for covert they are doing what is safest and best; but the plant is not hardy by any means, and therefore should not be depended upon for this purpose in any cold or low-lying districts. No doubt in certain elevated and favoured districts it lasts longer than elsewhere, but a great many are dead in the most favoured counties of England just now, or, if not dead, are cut very low by the frost and have a brown, unpleasant look which is quite unlike that of a truly hardy evergreen like the Holly, the Savin and the Box. As we never liked the Pontic Rhododendron very much, we made several little plantations of other kinds in the same position, as regards height above the sea, with a view to testing on them the power of frost. The result is that whilst our *catawbiense* are saved and hardy Rhododendrons on their own roots, such as Cunningham's White, are perfectly fresh and healthy, the Pontic Rhododendrons touching them are an ugly brown and dead to the ground.

We can now see the evil effects of using ponticum as a stock, because even if we selected hardy Rhododendrons and grafted them on a ponticum stock we should still probably lose them. Cunningham's White in our own plantation is on its own roots, but the ponticums that are dead are also on their own roots. Between the ponticum which is so much used as stock and the tender kinds of Rhododendrons of partly Indian origin a great deal of waste goes on in our plantations. We should select only hardy kinds raised from the North American species, and there are many beautiful ones of this kind which, if grown on their own roots, *i.e.*, raised from layers, might be depended upon to stand any winter. But we might also appeal to our great nurserymen to get

us substitutes for this tender ponticum, which is wrongly used to such a vast extent. They might easily propagate catawbiense and other hardy forms to take the place of the tender ponticum, which is clearly a much less hardy plant than the American species of Rhododendron which grow along the Alleghanies and other mountains in the Eastern States. The mischief of the ponticum is its facility of growth, which makes it so easy to raise, just as the common Laurel is easy to raise; and the growth is so obviously rank and quick, that the loss is all the greater in the end. Ponticum, as we have seen, is not hardy on its own roots, and when used as a stock in the end kills from its vigour the plants that are grafted upon it. So in the end we have ponticums everywhere in pleasure grounds where there ought to be fine old specimens of beautiful Rhododendrons.—*Field.*

**The common Box and the winter.**—Among the evergreens which have not perished this year from frost is the beautiful common Box, which is so seldom seen rightly grown in our shrubberies. The fact is, we have too great a wealth of so-called evergreens, and in such a rich mixture usually planted so that the good things can scarcely disentangle themselves from the crowd of tender rapid-growing things sure to perish in hard winters. In the usual shrubby crowd the Box is rarely seen properly developed and well grown; it is crowded, overshadowed, and mostly in places unsuited for it. In such circumstances it cannot be what it is in a wild state, a very charming shrub when fully exposed to the sun on an open hillside. Often in our gardens our wild trees are better grown than they are in the woods, but with the Box it is not so; no one has any idea what a beautiful bush it is who has not seen brakes of it wild, with its plummy, graceful toss of branches. And, therefore, to get its best expression, it ought to be treated in somewhat the same way, by planting bold groups of it—not generally mixing it at all with other shrubs, and certainly not allowing it to be overshadowed by trees of any kind. In that way we should get the simple and, as we think, the charming expression of this tree, which is a native of some of our southern hills, though not common. It would be an excellent thing to group here and there in coverts in open, sunny spots.—*Field.*

## KITCHEN GARDEN.

### TURNIPS.

ALTHOUGH the Turnip is one of the most free-growing esculents the gardener has to deal with, it is not always an easy matter to ensure a constant supply of juicy, well-flavoured roots throughout the year. The summer sowings are in some localities very liable to be attacked by fly, and for this pest there seems to be no effectual remedy. Dusting with tobacco powder or syringing with some insecticide if done in time would doubtless destroy or sufficiently check the insects, but this is in the case of large breadths too troublesome to be of much service. Dusting with soot has been tried with partial success, but it is difficult to get it on to the undersides of the leaves where the aphides do their work. In moist seasons Turnip culture is an easy matter, but when July and August are hot and dry the plants are apt to come to a standstill, the bulbs harden and never afterwards regain their natural crispness. The ground for the earlier sowings should be rich and thoroughly stirred. It should be borne in mind that there is safety in frequent sowings. It is a curious fact as regards the Turnip fly that whilst one lot of plants may be totally destroyed, another sowing made but a few days later will quite escape. This is frequently to be seen where large breadths are grown for market. I

have more than once remarked a large field annihilated in the course of a week, whilst a neighbouring field in which the plants came up some ten days later quite escaped.

Why this should be the case I have never been able to understand, but the ways of insect destroyers are sometimes mysterious. One may see this in the case of Roses, Strawberries, and other things which in one part of a garden will be badly affected by fly and mildew, whilst in other portions the plants may wholly escape. For frame culture, and especially where Turnips are forwarded by means of hotbeds, Early Milan is probably the best variety we have. The bulbs begin to swell before much leaf growth is made, and it is thus peculiarly well adapted for culture under glass at a time of year when the days are short and things brought on in warmth are apt to run overmuch to leaf. One cannot, moreover, err in employing this variety for the first sowing in the open air, although Snowball is very good for this purpose and many prefer it to any other kind. For an autumn supply I doubt if there is any better Turnip than the Early Six Weeks, this being much in favour with market growers, and Jersey Navet is one of the best late varieties. In a time of heat and drought, such as often prevails in July and August, there is a difficulty in ensuring the free germination of the seeds. In the case of small breadths the best way is to sow in drills, filling these up with water before sowing. This will give moisture enough to bring the plants through and start them freely into growth. Where Turnips are grown on a larger scale this plan is, of course, hardly practicable. Large growers hereabouts make a practice in a time of drought of following their land destined for autumn and winter Turnips, so that it is when required quite free from weeds of all kinds and a certain amount of moisture is retained in it. When sowing time arrives the ground is ploughed and fine harrows are kept at work for several days, so that the soil is brought into as fine and friable a condition as possible. A fine surface not only induces quick germination, but in some measure acting as a mulch helps to retain moisture in the soil below. It is prudent to make two sowings for winter use, one towards the end of July, the other a fortnight or three weeks later. One never knows what the weather will be like in the autumn. In a cold, wet season the earliest sowing will produce roots of just the right size; whereas after a fine autumn, when copious rains with bright sunshine and warm nights prevail, many of them will become far too gross and coarse for table use. Market growers usually make several sowings so as to make sure of a constant supply of sound saleable roots all through the autumn and winter. Any roots that may have got too big are fed off by sheep, so that there is no loss. Where Turnip greens are in frequent demand a sowing should be made in the last week of August, as the small bulbs stand severe winters much better than full grown ones. In this district all the Turnips are killed or crippled with the exception of the late sown. One man is fortunate in having about 7 acres of them, and they are in this time of scarcity quite a little gold mine. J. C. C.

*Sauvret.*

**Early Turnips.**—This vegetable is always appreciated early, and it may be had some weeks in advance of the usual time by sowing on a sloping sheltered border or at the foot of a south wall. Our early varieties, such as Snowball or Early White Stone, commonly called Six Weeks, though excellent for June supplies, are not the best for sowing for first crop. For years I grew the Early Paris Market, an oblong, early white French variety, but it is not so early as the Milan

section, of which there are two kinds, the Extra Early Milan and the White Milan, the former the earliest Turnip I have grown. It is a strap-leaved variety and quite a fortnight earlier than other kinds. It differs from the white in having a purple top and is round with a flattened root, whilst in favourable seasons it is one of the best for use in May. The White Milan is almost identical. I think it merely lacks the colour of the pink-topped variety. Those who can spare a frame will get a good return for the same, as the roots turn in so quickly, and I have noticed they are less subject to bolt or run when sown on heavy clay soil. To get the best results it is well to prepare a plot, and for heavy soils there is no better material than burnt garden refuse freely mixed with the soil.—G. W.

**Winter Onions.**—Many growers, myself among the number, will have cause to lament the loss of their winter-sown plants. Those in the northern part of the country who had more snow may be in a better position, but as far as I can learn for miles round not a root remains of some of the most popular kinds. Our plants stood well till the thaw, then all collapsed with the exception of the small Queen, a variety one would not have expected to stand. All others, such as the Tripoli section, White Lisbon, and Italian, have not a single good plant left. But we are fortunate, as at this date we have a quarter of green Onions that will prove most acceptable. They are in an out-of-the-way, exposed position and are not injured in the least. This being a singular circumstance, I will briefly relate how it occurred. Last season we had to thin heavily the spring-sown plants, which came up too thickly, and thinking the thinnings might be of service, these were laid in thickly in rows, and not being wanted no notice was taken of them. These are now growing freely, very few have died, and the roots will prove most acceptable, as there is a good breadth, showing that Onions at a certain stage will stand severe frost.—W. S. M.

### PLANTING SEAKALE IN SPRING.

Few persons who require Seakale in quantity adopt the old method of forcing in the open the same roots year after year, but resort to what may be rightly termed an improved mode of culture by planting root cuttings yearly, and thus securing in a shorter time good material for forcing. Some object to new ways, and think the old ones superior, but they would change their views had they a large family to supply with this vegetable for six months, from the middle of November till May. The winter we have just passed through shows the value of this vegetable, as at this date (March 30) there are few vegetables of any kind in the open ground, and Seakale is doubly valuable. If placed in heat in quantities as required about every fortnight there is always a supply of good quality if not forced too hard and in a dark place to get pure white growths. Much of the after success depends upon the way the roots are started and the time of planting. There is no difficulty in getting strong roots for forcing the same year if the plants are given a good start, and no matter what system is adopted, whether from root cuttings or from seed, it is well to get the planting roots intended for next season's forcing into growth at an early date. If seed is sown now thinly and the seedlings given ample space, they make good material for planting another season, but it is necessary to lift and trim the roots, cut off the crowns, and treat as advised for root cuttings. I favour root cuttings because they are so readily obtained, and at a time it is convenient to prepare them for early spring planting. Strong forcing roots provide just the material required, and make roots in one season if fed well and planted in good soil after being started in frames. Seakale to do well must have food. It roots deeply and likes a strong loam; but given ample food it is not fastidious as to soil. I find we get good roots on a light gravelly soil, but more food is required. Good planting roots

half a foot long are best, and, of course, the stronger the better if small plants or seedlings are used; the crown must be cut away, and root cuttings are cut even on the top. I prefer to place the food under the young roots and in liberal quantities, and to give plenty of room in rows not less than 2 feet apart between the rows and half the distance between the plants. In planting with a dibber make sure the root cutting is on the bottom, not leaving a space between the soil and plants. To get the best results, it is well to place the young planting roots in frames during the winter. About three weeks before planting they are placed in rich soil in boxes in rows rather close together, and planted about the third week in April. Each plant will then have a mass of fibrous roots, and with prepared plants like these it is well to plant in drills, using a spade. This is better than a dibber, for the roots are spread out, and in poor soil such aids as wood ashes, fish manure, or guano may be placed in the drill. During growth the plants are restricted to one crown, the strongest, and frequent dressings of soot and fish manure are given in showery weather. G. WYTHES.

### TOMATOES AND DISEASE.

RECENTLY we had an instructive paper at a meeting of the Royal Horticultural Society on "Diseases of the Tomato," and I, in common with others, attended to gain some information, as I have suffered badly at times and have been obliged to clear whole houses to arrest decay of fruits. Mr. Collinette in his paper introduced two diseases we have not had much experience of, or at least I have not, and trust it is a local disease that will not be imported. One closely resembles the curl, and may be the same under another name and have different effects in the warmer climate referred to, so that we may not be as free from its evil effects as imagined. In the discussion which followed, Mr. Douglas stated that his plants did not suffer from disease, and thought it was a cultural defect, but I fail to see this, as persons who only grow Tomatoes, and often in a large way, paying every attention to culture, suffer badly. Mr. Douglas stated he had on one occasion been troubled with white-fly; he soon got rid of it, and was now growing plants yearly and had no disease trouble whatever. I wish most growers were in a similar position, as in many cases I find the disease increasing. Another gentleman at the meeting thought a close, humid atmosphere aggravated the disease, and doubtless such is the case, but not to the extent one may imagine, as plants in the open are subject to various diseases. I have found there is no means of escape even in the most favourable seasons; for instance, in 1893 one could air as much as one liked and still there was disease. I am of the same opinion as Mr. Collinette. Disease is hereditary; it is transmitted by diseased seed, and to a certain extent assisted to spread by bad culture, probably by a humid atmosphere. For a few years I have saved my own seed of various kinds, not from unhealthy plants, but from the first crop and of best shaped fruits. Some kinds are more subject to disease, especially the large varieties. I have never had a plant of Conference diseased, whilst whole crops of Chemin have failed. Perhaps Mr. Douglas does not grow many varieties, and he may have more favourable positions for his houses; he certainly is fortunate in his immunity from disease with these plants when so many suffer. GROWER

**Wintering Lettuces under walls.**—An old saw tells us not to put all our eggs in one basket, and its truth is very apparent in many ways just now. Lettuces that were planted in the autumn for the earliest crop close up to south walls have nearly all been killed, as the sun had thawed the snow from them before the severe frost was over. Plants left in the seed beds and others pricked out on the open borders at some distance from the walls have come through the winter without a loss, and are now being planted

by the thousand into open quarters, later on to be occupied by Celery, where they will soon grow and be cut for use in quick succession to others put in warmer positions. Early saladings will be scarce this year, and such plants ought to pay well for planting in quantity now. The variety which has stood the winter best is the old Bath Brown Cos, but Hammersmith Cabbage Lettuce will be ready for cutting earlier than any of the Cos varieties.—J. C. TALLACK.

**Veitch's Autumn Giant Cauliflower.**—By sowing a pinch of seed early in September, pricking the plants out into a frame when large enough to handle, keeping them stocky through the winter and planting out towards the end of March, I am able to cut nice heads of this Cauliflower at the end of July and throughout August. In no other way can this Cauliflower be had in good condition at that season.—E. M.

**Spawning Mushroom beds.**—Spawning is often, I think, unduly deferred. Many allow their beds to fall to 80° and even 70° before inserting the spawn; consequently after the operation the heat rapidly declines and the spawn remains inactive for a long period. The above figures are all very well where the beds are of more than ordinary depth, but where no more than a foot or 15 inches deep the spawn may safely be inserted at 90°, as there is little or no fear of any reaction in the heat. Spawed at this figure and well covered with dry oat straw, beds will often show Mushrooms at the end of a month and continue to yield over a longer period than those that are spawed at a much lower figure.—J. C.

## GARDEN FLORA.

### PLATE 1010.

#### VANDAS.

(WITH A COLOURED PLATE OF V. SUAVIS.\*)

It was on the introduction in 1847 of the well-known *V. suavis* and *V. tricolor* in one importation that the value of *Vandas* began to be apparent, and since then the genus has been constantly enriched. *Vandas*, except in a few instances, are easily managed. They include also some of the most stately habited of Asiatic Orchids, and this, combined with their handsome evergreen foliage, makes them attractive at every season of the year.

About thirty species are known, these being spread over a wide area in Tropical Asia; from the Himalayas they stretch southwards and eastwards through India and Burma to the islands of the Malayan Archipelago, one species even reaching Australia. They are always epiphytal, the leaves being mostly arranged in a distichous manner, and are usually strap-shaped, although in a few species they are nearly or quite terete.

In regard to the cultivation of these plants, it is impossible, especially in the matters of temperatures and moisture, to speak of them as a whole. The widely separate localities over which they are spread, and the peculiar climatal conditions which attend the growth of individual species, necessitate in several instances marked differences in the methods of cultivation. The majority of the species, however, especially those of dwarf growth, require identical conditions, and, except where stated otherwise, the following particulars as to treatment may be taken as applying to the whole of those here mentioned. They may be grown in pots, baskets or cylinders; for the dwarfier kinds the two last are preferable, pots being generally used for the stronger growers like

\* Drawn for THE GARDEN in the Royal Gardens, Kew, by J. Allen. Lithographed and printed by Guillaume Severynus.

*V. suavis* and *tricolor*. In whichever of these they may be planted the lower two-thirds of the space should be filled with drainage, the remainder with clean living Sphagnum. No species requires peat or any like material about the roots, but when large pots have to be used a few lumps of charcoal or porous brick may be mixed with the Sphagnum. Whilst *Vandas* may be termed stove plants they do not require such essentially tropical conditions as some Orchids, such as *Phalenopsis* do, and mistakes are more frequently made in giving too high a temperature than in the other direction. A winter temperature of 55° to 60° and a summer one of 65° to 80° will be found sufficiently high, the lower figures indicating the night temperatures. A point of great importance in the successful cultivation of all the species is that they should have the greatest possible amount of light, short of causing actual discoloration or damage to the foliage. It is found that by keeping the plants within a few inches of the glass and shading only when the sun's rays are most powerful, not only is the foliage harder and sturdier, but the flowering is more regular and profuse, and the blooms themselves of better colour. During the growing season an abundant supply of moisture at the roots is indispensable, and as a considerable proportion of these are usually outside the pot or basket, the necessity of maintaining a moisture laden atmosphere is forcibly suggested. In the matter of ventilation a regular supply of fresh air without permitting a cold current to pass over the plants should be aimed at. In winter the supply of moisture should be greatly reduced, but the Sphagnum should, nevertheless, be kept slightly moist at all times. As soon in spring as the tips of the roots show signs of renewed activity by pushing forth green points, the dead Sphagnum should be replaced by new, and the drainage put in good order. When the roots have attached themselves to the sides of the pots or baskets, care should be taken not to disturb them; the material which has to be replaced can generally be removed by the aid of a pointed stick and by syringing. For the same reason it is advisable, when more root room is desirable, to place the old pot with its roots attached inside a larger one.

*V. AMESIANA.*—This dwarf growing variety was introduced by Messrs. Low, of Clapton, from Upper Burma. The flowers are on tall erect spikes, the sepals and petals white, flushed with rose; the lip rich magenta-rose, with paler coloured margins. From twenty to fifty flowers have been borne on one spike, and as many as eighty have been counted on imported spikes. This species may be grown in an intermediate or even cool house.

*V. KIMBALLIANA.*—It is also to Messrs. Low that we owe the introduction of this *Vanda*. It comes from the same country as *V. Amesiana*, and is nearer to it in relationship than any other. It is undoubtedly one of the loveliest of the genus. It has leaves still narrower than those of *V. Amesiana* and almost terete. The flowers are between 2 inches and 3 inches in diameter, and from six to nine are borne on the spike. The sepals and petals are sometimes of a pure white, sometimes flushed with rose, a beautiful contrast being made by the rich rosy purple of the lip. It requires the same temperature as *V. Amesiana*.

*V. TERES* AND *V. HOOKERIANA.*—These two species are distinct from other *Vandas* on account of their terete foliage. As a garden plant, *V. teres* is the superior. It has dark green stems about the thickness of a goose-quill, and cylindrical leaves about 6 inches long. From three to six flowers are borne on the raceme, each of which is 3 inches across. The oblong sepals are white

tinged with rose, the large and more rounded petals being deep rose. The lip is very showy; in front it is of a rich rose veined with orange, but in the throat the latter forms the ground colour, and it is spotted and striped with crimson. It is a native of Burmah and Northern India. *V. Hookeriana* is easily distinguished from *V. teres* by its paler green, more pointed and smaller leaves. The racemes usually carry two flowers. The sepals are white, tinged with rose; the petals larger, more spatulate, and spotted with magenta. The lip is  $1\frac{1}{2}$  inches wide; in front it is of a purple-tinted white, spotted with magenta towards the edges, streaks of the same colour occurring in the centre. *V. teres* was introduced in 1828, but it was not until 1873 that *V. Hookeriana* was seen in English gardens. The cultivation of these two species is different in some respects from that of other Vandas. They require the greatest possible amount of sunshine to induce them to flower, and may be kept pretty well unshaded at all times. In summer the night temperature should not fall below 70°, and an abundance of moisture must be given. It has been found a good plan to set apart one light of a well-heated frame for them, planting pieces about a foot long in a bed of Sphagnum 4 inches deep, draining it well. In the growing season the frame may be shut up and syringed about 4 o'clock, putting on again before evening a crack of air. In winter they may be kept quite dry in a temperature of 55° to 60°. The essential points, therefore, in the cultivation of these two species, more especially of *V. teres*, are unrestricted light, a high degree of heat and moisture, and a thorough ripening off in autumn and winter.

*V. SUAVIS* AND *V. TRICOLOR*.—For general garden work there can be no doubt that these two species are the best of Vandas. In habit both are stately and handsome; they grow well with other plants, and they illustrate, moreover, a style of growth which is comparatively rare in plant houses. Reichenbach considered them to be varieties of one species. Out of flower they are indistinguishable, and in flower the chief distinguishing character is in the ground colour of the sepals and petals, which in *V. suavis* is white, whereas in *tricolor* it is yellow. They are both natives of Java. The commonest error in the cultivation of these two species is in giving them too high a temperature and too much shade. They are intermediate rather than stove plants, and a minimum winter temperature of 50° will suit them.

*V. CERULEA*.—This species blooms in late autumn, and at that season there is no Orchid which excels it in the wealth and beauty of its flowers. The spikes, two of which not unfrequently appear simultaneously on one plant, carry from ten to twenty flowers; the latter number, however, very rarely, and only on newly-imported plants or on those of extraordinary vigour. In the best varieties each flower is 4 inches in diameter, and the sepals and petals (which ought to slightly overlap each other) are of a lovely pale lavender-blue, tessellated with a darker shade. The lip is small, but of a yet deeper blue. It is a plant of erect habit, with two opposite rows of dark green rigid leaves each 6 inches to 8 inches long and strap-shaped. This species has acquired the reputation of being a difficult one to deal with, and no doubt with some justice.

*V. SANDERIANA*.—Whilst this species does not possess the charm and delicate colouring of *V. cerulea*, it is, on the other hand, the largest-flowered and showiest of Vandas. The flowers are each 5 inches across, and a dozen or more are produced on one spike. The upper sepal and petals are pale rosy lilac tinged with yellow and have also crimson dots at the base. The lower sepals are 2 inches in diameter, fawn-coloured and reticulated with brownish crimson. The lip is small and of a dull crimson. Notwithstanding their marked structural differences, the flowers strongly suggest those of *Odontoglossum vexillarium*. The species was introduced in 1881 from Mindanao, one of the Philippine Islands, and first

flowered in Mr. Lee's collection near Leatherhead.

*V. CATHARTI* is a tall-growing plant with slender, terete stems and pale green, narrowly oblong leaves 6 inches long. It is a handsome species, but does not flower freely as a rule. The flowers are upwards of 4 inches in diameter, with broad oblong sepals and petals, the ground colour of which is pale yellow, but marked with bars of reddish brown. The lip is white with a tinge of red on the side lobes, whilst the large central lobe has a yellow incurved margin. Sir Joseph Hooker discovered this species in the hot valleys of the Eastern Himalayas. It has been most successfully grown when trained on a damp wall, and differs from most Vandas in preferring a good deal of shade.

There are still to be mentioned a number of dwarf growing species, which form a beautiful and important section of the genus. *V. Bensoni* is a charming species with flowers 2 inches across, whose sepals and petals are marked with numerous red-brown dots on a yellowish ground, whilst the lip is of a soft violet. *V. cerulescens*, as the name implies, has flowers in which the prevailing tint is blue. They are over an inch across, the sepals and petals being pale purplish blue and the lip a rich violet-blue. This delightful plant should be in every collection, a remark which applies as strongly to *V. Denisoniana*, whose beautiful white flowers render it distinct from all other Vandas. The true *V. insignis* is not a common Orchid, what is generally known under the name being a totally different plant and a variety of *V. tricolor*; the true plant has tawny yellow sepals and petals, blotched with dark reddish brown, and a lip of a delicate rosy white. *V. Parishii* is distinct by reason of its handsome bright green leaves, which are oblong and unusually thick and firm. The outer segments of the flower are of a greenish yellow spotted with bright reddish brown, the lip being white, striped with orange at the base, but magenta in front. *V. Roxburghii* has pale green sepals and petals tessellated with olive-brown, the lip being violet-purple and white. In this and various other species of *Vanda* the outside of the sepals and petals is white.

W. J. B.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**BEANS IN FRAMES.**—A short time ago I advised the sowing of *Syon House* and *Ne Plus Ultra* French Beans in small pots with a view to transplanting them into frames during the month of April. If after growth commenced this batch was given a cooler temperature, they will be robust and hardy, with thick, dark, fleshy leaves, a condition absolutely necessary if good progress and full crops are to be secured in cool frame temperature. As a rule in fairly large establishments several frames recently occupied by Endive, Lettuce, Cauliflowers, and Cabbage will now be empty, and if the soil in which these have been growing is fairly rich and dry it need not be removed, but some fresh added to it, stirring in somewhat freely an approved fertiliser. Close the frames for a few days to thoroughly warm the compost through, after which plant in rows 18 inches apart, disturbing the balls as little as possible, and planting not too deeply, so as to avoid stem-rotting. If the soil is in a semi-moist condition, no water will be required for the present, beyond settling the compost about the roots. If the frames are kept rather close for ten days the plants will quickly become established, and with increased air and overhead syringing on fine afternoons at closing time growth will be strong and rapid. This early closing must not be overlooked, as the nights may be cold for some time to come,

and the difference between plants which have the benefit of husbanded sun heat and those which have it not will be apparent. If a frame or two in which *Asparagus* has been forced can be spared, it will pay to re-pot a portion of this batch into 9 inch pots, and plunge them in the partly exhausted bed of leaves on which the frame stands, if necessary adding a fresh lining of leaves and stable litter. The roots being confined in pots will induce a moderate growth and earlier cropping than will be case with those planted out in the unheated frames, these last forming a succession. Where the pits or frames are of sufficient depth to allow of it, Canadian Wonder may be grown in this way, using soil free from manure, as this Bean is so prone to rank growth if at all stimulated in the earlier stages. Coverings of double mats will, of course, be necessary every night for some time to come. In warm sheltered gardens the first-named varieties of the same age and height may be planted out on a south border, to be protected from frosts and wind by the erection of a rough framework, the same being covered at eventide by canvas or ordinary garden mats. On frosty mornings the covering must remain on till after breakfast. One great point in early outdoor culture is to work in amongst and around the roots a quantity of fine semi-dry soil. Do not sink the plants in trenches, as some do for protection, but rather place a few Yew boughs here and there on either side of the rows. Slugs often play havoc with this batch, a few of these pests unobserved ruining the whole lot in a few nights. The best plan is to sprinkle soot and lime thinly over the surface of the ground at planting time, renewing this after rain until the Beans grow out of harm's way. Sowing the seed in the open ground had better be deferred till the first week in May, and even then a very sunny site will be necessary, coupled with a warm, well-drained soil. Sow plenty of seed, as Beans are not in the best condition this season, and thinning to any extent can be practised if the plants should be too thick.

**SUCCESSIONAL TOMATOES.**—The present is a good time to sow seed for the production of plants to fruit in cooler houses either in boxes or pots, the growth being trained up the roof glass or in an upright manner to stout stakes. These will follow the second earliest lot now being grown on in an intermediate heat. The Old Red is still one of the best. Sensation, Jubilee, a good strain of Perfection, and Conqueror are useful. If weight of fruit to the individual plant is the main thing, Oxonian, a variety sent out last year, is worthy of cultivation, the fruit being simply enormous, and well adapted for cooking or for converting into sauce. Where small lunch-sized Tomatoes are in request, the old Trentham Fillbasket is a useful kind and a good bearer, and where the desire is to have a variety which, in addition to being a heavy and continuous cropper, is likewise fit for exhibition, I cannot name a better than Webb's Regina. One noted grower for market after growing it on a moderate scale last year decided to make that his sheet anchor in 1895, so good was it in every respect. Plants raised recently for outdoor work must be brought on under as cool conditions as possible, and subjected to all the fresh air and as dry an atmosphere as can be given; too much heat and a stuffy atmosphere will lay the plants open to attacks from the dreaded disease when they are exposed against open walls. Some of the very best results are obtained from plants in 10-inch pots, these being plunged in the border at the foot of the wall and well mulched to preserve the moisture. If half the plants is so treated and the remaining half planted in the ordinary manner, a supply over a longer period will be secured, as those in the pots will ripen a fortnight sooner than the planted out ones. It must, however, be borne in mind that, owing to their confined condition and a multiplicity of roots, a good amount of nourishment will be indispensable.

**MAIN-CROP BEET.**—From the present time to the end of the month is a good time to sow Beet for the principal winter supply. I know that some advocate sowing in May, but should the

summer turn out wet and cold or excessively dry, the roots often do not attain to much more than half their normal size, as practical men do not care to sow Beet on richly manured land. A good deal depends on the variety, as some sorts, although catalogued as medium-sized and even small, will, even on unmanured land if it is in fairly good heart, grow coarse and woolly in spite of late sowings and little thinning. For my own part I prefer Veitch's Selected Red as an all-round table Beet, it being of medium size and very rich colour, and quite free from white rings, so noticeable in some Beets; its flavour also is irreproachable. Nutting's Dwarf Red is a capital old Beet, Dell's being hard to beat where an extra dark-fleshed variety is wanted. A lightish soil, free from stones and of fair depth, and that has been cropped since manure was dug in, is what is wanted. Moderation also in thinning out the young plants is necessary, as if too much space is left between them any kind will grow to an ungainly size.

**PARSLEY.**—The end of April is a good time to sow for the principal winter supply. One or more batches should occupy ground that can be conveniently covered with frames as soon as bad weather comes on in November or December. From this sowing also transplantings may be made for the purpose of lifting in autumn and placing in frames or pits for winter pickings. In this case plenty of room must be allowed between each plant in order that lifting may be made easy and a ball of soil be secured. I generally sow in July for early spring use, protecting the young plants during winter with a frame. This lot springs into new growth in February or March, and soon gives a good supply. The ground should always be specially prepared for Parsley by the admixture of plenty of insect-proof ingredients, such as soot, gas-lime, and wood ashes. This is a good mixture for banishing wireworm, the chief enemy to Parsley roots.

**POTATOES IN POTS.**—Where these are grown for a few early dishes the haulm will now be assuming a yellowish cast. The tubers also will be of fair size. Less water and increased volumes of fresh air will likewise be needed to impart flavour and prevent them from eating watery. Later lots must be well nourished.

**SEAKALE.**—Where the produce from beds forced by means of pots and leaves has been cut, means must now be taken to gradually harden off the stools previous to complete exposure. The lids of the pots should be removed each morning, and replaced again at eventide. After this treatment for a fortnight the pots may be removed and the crowns just covered with a few leaves, this being taken off after a similar period.

**PLANTING SEAKALE.**—A fortnight ago I advised planting a portion of the more forward root cuttings in a sunny aspect for supplying crowns for early November forcing. The main lot may now be planted, as this will have a longer rest after shedding its leaves in autumn before being placed in heat. More manure may be dug in than is advisable with the earlier lot above referred to. Plenty of space also is essential both between the rows and from plant to plant. From those that are well sprouted remove all but three, and draw a little soil over them to protect the tender growth from frost. Frequently slugs and other pests are troublesome, eating off the young leaves as they begin to develop. Sparrows also and wood pigeons often attack them, hence the need for occasional sprinklings of soot and wood ashes. Malt dust is a capital manure for Seakale. It may be dug in at the start, and likewise applied in the form of a top dressing after growth has advanced somewhat. The rains will then wash in its virtues.

**PRICKING OUT.**—There will now be a considerable amount of this work amongst seedlings of various early vegetables. Early Celery, Lettuce, Cabbages, and Cauliflowers must not be neglected in this respect, or no amount of after attention will atone for it. See also that the boxes containing such things are removed from the germinating quarters to cooler ones in due time, as if once the seedlings are allowed to become leggy and fall

about, they seldom take kindly to the soil when pricked off. In a cooler position they come on slowly but surely, and can then be attended to from time to time.

**HOING AND CLEANING.**—A good deal of this will now be needed amongst the earlier green crops, as ill weeds grow apace. Spring Cabbages and Spinach are much benefited by frequent surface stirring to remove small weeds and admit air. After hoeing, a little soil should be drawn up to the plants of the former. Onions will require hand-weeding, firming, and a broadcast stimulant, using the thick-necked ones for present kitchen use. Ground should now be got in readiness for the earliest Leeks. They may be grown either in trenches or on the level; if the latter, holes should be made with a dibber some 9 inches in depth, and the young plants dropped down to the bottom, a little soil afterwards being forced in to cover the roots. Plenty of rich food is necessary for this crop, as the larger they grow the better.

**HERBS.**—The more tender sorts of those sown some time since in heat will now be fit for hardening off, and in a fortnight's time may be transplanted, giving them some fine soil to start in. Seeds also of all the more hardy robust herbs may now be sown in the open border. J. CRAWFORD.

### FRUIT HOUSES.

**BANANAS.**—Those who grow Bananas will now find it advantageous to feed liberally plants that have thrown up fruits and to top-dress with short manure. Musa Cavendishi is the best variety for most growers, owing to its dwarf habit, and though thought inferior, the fruits are greatly superior to those imported. Many can grow a few plants in large pots or tubs who cannot devote a house to their culture, and frequently plants grown in this way are more profitable, as when a house is devoted to them they are, like Negro Largo Figs with a large root area, prone to much leaf growth and few fruits, whereas with restricted root growth they can be better managed. Large plants that have not fruited should not be allowed to produce suckers too freely. Any plants large enough to fruit should be kept on the dry side till the flowers show, when more moisture and rich food in the way of liquid manure should be given, top-dressing with some artificial manure. A high temperature with ample moisture in all parts of the house is necessary. Fruiting plants should have a heat of 70° at night with 10° higher by day, though excellent fruits may be cut from M. Cavendishi grown in a temperature 10° lower than the average given, allowing it to run up freely at closing time. Plants that are grown slowly at times are longer in pushing up their fruit, and if stationary too long the fruits decay in the stem, so that it is advisable to supply more warmth at this season.

**SUCCESSION PLANTS.**—Suckers taken from fruiting plants now if strong and potted on will make fruiting plants for next spring. I prefer suckers taken in April or May, as they winter better, do well in a low temperature, and show fruits in about twelve months from time of potting. Earlier suckers are apt to show in the autumn, and they do not thrive so well, making a poor growth. In some cases there is a difficulty in getting the fruit free of the leaves. The compost should be good rough, turfy loam, with some decayed manure and small bones or bone meal, potting firmly and shading for a short time. Short, sturdy suckers are preferable to large pieces with drawn leaves. If extra strong suckers can be obtained and planted at once, it is important that they get good drainage, rich soil, and plenty of warmth from the start. Kept in a dry hot-house, the foliage soon gets infested with red spider and thrips. Smoking occasionally is necessary, and in syringing it is well to lightly damp overhead, as the deep midrib conveys the water into the heart of the plant in greater quantities than is desirable. If planted out in beds, it is well to restrict root space not so much in width as depth. If planted too deeply, the plants in dark houses or mixed with other plants decay at the

collar and fall just before the fruit forms. It is always well to renew the border after fruiting, as the soil is impoverished, giving new drainage before replanting.

**STRAWBERRIES IN POTS.**—The earlier fruits will now be at the ripening stage, and need care to obtain flavour. Too much water in dull, sunless weather will cause poor flavour, and if the plants are in strong heat in a moist house the flavour will be second-rate. Objection is taken to forced Strawberries by many owing to the lack of flavour, but to a certain extent this may be avoided from this date. With earlier crops it is more difficult, as there is not time to get flavour by adopting cooler treatment. Those who force in quantity and are able to devote whole houses to the plants will be in a position to lower the temperature and keep the house drier. Much can be done by careful removal to a small pit or house where the plants may be given more air, and thus obtain the brisk acid taste so desirable. Manures are often given too late, and thus affect flavour. I feel sure many plants would be much benefited by giving manure just as the flower-spike is pushing up, not waiting till the fruits are formed. Strawberries fruiting in vineries should be removed as early as possible, as the plants are so subject to red spider and mildew.

**SUCCESSION CROPS** will now come so freely, that there is no fear as to their cropping qualities if specially grown for forcing. Thinning should be done early as the plants soon feel the strain of a heavy set. Thinning should be done according to the size of fruit. Such a large kind as Auguste Nicaise, a very fine mid-season variety, requires more thinning than Keens' Seedling, six fruits being ample, whereas eight to ten may be left on others of less size. For fruiting in May I always depend on President, one of our very best forcing varieties. Its chief fault is that it mildews badly, and if not grown against the glass the foliage gets much drawn. To follow this Sir C. Napier is always good, the fruits firm, solid, and of grand colour. To get these varieties good it is well to force slowly from the start. There is often a difficult period to bridge over by those who force Strawberries—that is the end of May, as in many gardens the forced plants are over, and those in the open not nearly ripe. In such seasons as 1893 the outside crop was ready by the end of May, but it rarely happens we have such favourable weather. The plants in the open this season have been much cut by severe frosts, so will be late. I find it a good plan to place a few hundred plants in cold frames about the end of April, these providing a supply at the time named. I do not advise growing on shelves or stages, but on a cool ash bottom. Grown thus, there is less watering, insect pests are few, and the flavour is equal to that of outdoor plants. Of course grown thus it is necessary to stake all the flower trusses and to grow near the light. Frames that have wintered plants may be made good use of. Many shifts have to be made at times to obtain a late supply for frames. Treated as advised, it is not necessary to keep the pot plants. Should there be a scarcity I have found that young plants lifted with a ball do well, and though they must be well thinned, good-sized fruits are obtained. The much-abused Noble does well given cold frame treatment and the flavour is very fair. Those who require late Strawberries after the permanent beds are over would do well to harden their forced plants of Vicomtesse and La Grosse Suerée. These planted out in richly-manured land will furnish a good autumn crop.

**CHERRIES** under glass will need more attention just now than at any other period whilst being forced. The Cherry being so subject to the attacks of aphides, frequent fumigation is necessary, doing the work twice or thrice in succession, and choosing a quiet time for the work. Trees grown in cases will need a liberal supply of moisture, and as soon as a good set is secured the syringe should be used freely to keep red spider at a distance and promote a free growth. The damping overhead having been discontinued during the flowering period must be resumed as

soon as a good set is secured. The trees also will require water, and as the fruits swell warm liquid manure should be given. The temperature now may range from 60° to 65° by day with 10° lower at night. Air freely during bright sunshine, and do not attempt any thinning of the fruit till the growth is somewhat advanced.

**PEACHES IN CASES.**—Late trees in cases or those merely given glass protection will now be flowering freely. Plenty of air should be given during the day, and there should be no lack of buds on well-managed trees. In many cases the flowers will be so thickly packed that it will benefit the trees to remove badly placed flowers, thus giving the more prominent ones room to expand freely. Fertilising the flowers in light airy cases will not now be necessary; bees will do the work much better. As regards thinning, my remarks apply to vigorous trees and those overdone with bloom. Fumigating must be well attended to, and it is necessary to do the work as soon as the fruits have set, as green or black fly soon cripples the young shoots, and once the leaves get into a curled state the fly is more difficult to get rid of, the leaf protecting the enemy. Watering will be necessary, and it is well to use water of the same temperature as the house. Water thoroughly and disbud as soon as the shoots are on the move, doing a portion of each tree daily.

G. WITHERS.

## ORCHARD AND FRUIT GARDEN.

### HARDY FRUIT CULTURE.

IN face of the magnificent fruit prospects no doubt many will be watching the weather with more than ordinary interest for the next few weeks, especially those whose livelihood depends in a great measure on the crops. So far the weather has been in the grower's favour, as trees are much later than last year. At this date (April 6) last spring all our Plum trees were in full bloom, but even with warm weather the flowers will not expand under another fortnight this season, all of which makes spring frost less dangerous. However, though we have an advantage in that respect, the severe winter and late spring do not appear to have acted as a check on the hatching of insect eggs, as I found to-day the larvae of the winter moth just hatched on Plum, Apple, and Pear trees in quantity, and have commenced spraying with 1 oz. of Paris green to every 20 gallons of water. On Apple trees aphides are appearing, and no time should be lost in dealing with this pest while in its infancy. Whatever insecticide is employed for its destruction, I would strongly suggest applying it warm, as it is more effectual. Red spider is alive on many Gooseberry bushes, and it will be a good plan to spray them with a suitable remedy early, taking care to force the liquid to the underside of the foliage. In Raspberry plantations the Raspberry-bud caterpillar (*Lampronia rubiella*) is just commencing to appear, the buds failing to grow or drooping. If these buds are taken off, a small red grub will be found in each. Hand-picking is the best and most efficacious remedy at this season. A whole host of injurious insects could be named that the fruit grower has to fight against if he means to make his calling a success, and I believe insect destruction is one of the most important items in hardy fruit culture. If we could give the same amount of care and attention to fruit trees outside as given to those under glass, what splendid results would be obtained. Unfortunately, it is practically impossible to do so in the great majority of gardens, as the labour is totally inadequate to attempt anything of this sort without neglecting other work that must have attention if the

ordinary supply of vegetables, flowers, &c., is to be kept going. In some few gardens, both large and small, sufficient labour is provided for all requirements that may arise, and in such instances I would suggest bestowing extra care and attention on a few trees of different kinds, disbudbing them just the same as if grown under glass, stopping all shoots that appear unduly strong, syringing them once or twice daily, according to the state of the weather, and liberally thinning out the fruit when it is fairly set; also supplying sufficient manure for the full development of growth and fruit. By giving the trees of any sort such good culture, fruit will be produced of magnificent proportions and remarkably fine in colour and flavour, as proved by actual experience when I had more time to attend to these details. In growing for market I question if it would pay to bestow so much attention on the trees, as the labour bill would be heavy in a large plantation; still I should not like to state that it would be unprofitable, as I have sold Warner's King wholesale at 2s. 6d. per dozen fruits from trees treated as mentioned above. But the private grower is differently placed to the market man, as he does not grow for profit, but for his own use and pleasure, and expense of production is a secondary matter. When this is the case, I think nothing gives more pleasure or interest to the owner than to see his fruit daily developing into specimens infinitely superior to anything of the kind he can see elsewhere. Not only so, but the grower of such fruit confers a benefit on the neighbourhood, as he shows in a practical manner what can be done in fruit growing by giving the trees high culture, and he may be perfectly sure that others will be stirred up to follow his good example. We hear a great deal about over-production, low prices, bad prospects for all connected with the land and its cultivation, but in spite of such pessimistic views there is still money to be made by fruit growing if conducted on proper lines.

W. G. C.

### GRAPES FAILING TO SET.

IN reading the remarks on this subject at page 193 I observe that "W. G. C." had a good set of Muscats with the temperature at night as low as 45°. The question of low versus high temperatures for Muscats or indeed any varieties of Grapes has often been discussed, and as far as the evidence has been forthcoming from the best sources, it has told in favour of the higher temperatures. It will be observed that in the case alluded to the days were bright and favourable. If the weather had been bad with little or no sun-shine, the low night temperature might have been disastrous. I quite agree with "W. G. C." as to the importance of having the roots in good condition; that is of primary importance, but it is not everything. Our house of early Vines was in flower as early as February this year, and I greatly fear if we had been obliged to have the temperature so low as 45° as a minimum, that two varieties of Grapes would have failed to set. These are Madresfield Court Black Muscat and Venn's Muscat, which is presumably merely Snow's Muscat or the still older Black Muscat of Alexandria. The Buckland Sweetwater and Black Hamburg are both free-setting varieties, but even with these I would be afraid to trust their setting in such an exceptionally low temperature. I kept the minimum temperature well up to 65°, but there was not much rise above this by day; probably 70° would be the average day temperature. The atmospheric conditions have to be considered. A dryish atmosphere is best, and once every day, about noon or soon after, the bunches are gently shaken, and the pollen is conveyed from the Black Hamburg variety to any others that are known to be shy setters. My plan is to tie a

rabbit's tail to a stiek and draw it over the bunches of the Black Hamburg. It comes off them laden with pollen, and we merely touch the bunches of say Snow's Muscat and Madresfield Court Muscat with the fur of the rabbit. In some cases a small globule of moisture is attached to the stigmatic part of the flowers, and unless this globule is dispersed, the pollen cannot touch the stigma. The best way, or at least a good way, to remove it is to draw the hand over the bunches and also give them a gentle shake. Of course, the condition of the Vines at the time of setting has a good deal to do with success or partial failure. My plan is to give the Vines a thorough watering when the house is started, and another good supply is given when the bunches begin to open out, say a week previous to flowering. This second watering will carry the Vines into the stoning period, when they may again be watered. How much water should we apply to the Vines at one time? is a question frequently asked, just as people ask, "How often shall I water my Pelargoniums, Fuchsias, &c.?" In the case of the Vine border the question is more easily answered. I give a border about 12 feet wide and 30 feet long about 300 gallons of water, and at the time that I was a frequent exhibitor of Grapes at the metropolitan and other flower shows in May and June I used to heat a copper of water, and as the water was being applied to the Grape Vines enough warm water was added to heat it to a temperature of between 90° and 100°. I have won first prizes with Muscats in the last week in May, and I remember growing twelve bunches of Buckland Sweetwater on one rod, and every one of them was exhibited and all won first prizes. This variety was planted at the end of the earlyinery, and close to the wall on the other side was a large boiler which heated theinery in question and three other hothouses, so that the furnace was seldom out summer or winter. The berries on these bunches were quite of a golden colour. This is evidence that the artificial heating of Vine borders is sometimes productive of good. It may be harmful if care is not taken to apply much larger quantities of water to the artificially heated border. As bearing upon the setting of the fruit, I found that there was no trouble with the Buckland Sweetwater near the heated part of the border, but a plant near the other end of the house would have badly stoned berries sometimes. A dryish atmosphere is essential to a good set of Grapes.

J. DOUGLAS.

**Planting young Apple trees amongst old ones.**—How often even now do we see this error committed, although not one single point can be advanced in its favour. In the first place the root-run is generally impoverished by the older occupants of the orchard, while their branches produce such a dense shade that any young trees planted in the intermediate spaces stand no chance whatever of receiving light, air, or sun. Usually this kind of planting is carried out when the old trees show signs of exhaustion and decay. This being so, the better way would be to sacrifice one-half of the old trees, trench and enrich the soil by liberal additions of loam and manure, and plant the young trees. The other half might be retained till these come into bearing, when it could likewise be renewed and replanted. At any rate, planting young trees amongst old ones is a most unpractical and unprofitable proceeding.—J. C.

**A letter from Russia.**—I have the pleasure of sending you some scions of a species of Cherry which is grown on its own roots and which is propagated and multiplied by means of its suckers. It is unquestionably the best kind of Griotte Cherry, and in the north of Russia, in the government of Vladimir, and especially at Viazniki, there are very extensive plantations of this species alone. The fruit is fair-sized and red skinned and the juice of it stains deeply. When quite ripe the flesh is sugary and pleasantly acidulous, in fact very agreeable to the taste. From it are made preserves and very delicious liqueurs, and it

is also eaten fresh from the tree, or dried, &c. The tree grows to a medium height, is very hardy, remarkably productive, and very constantly so. When a tree appears to be worn out it is cut down close to the ground, and of the numerous shoots which are emitted from the stump one of the strongest is selected and retained, to be trained and grown as a bush or half standard. The Cherry tree in question has many synonyms, the commonest of which are Cerise Vladimirskaia, C. Viaznikovskaia, and C. Roditelera.—LEON SIMIRENKO.

**Liquid manure for fruit trees during winter.**—Few persons appear to realise the benefit that fruit trees derive from having their roots thoroughly soaked during the winter with liquid manure. Too much of this is allowed to run to waste where there is a tank in connection with the cowhouse or stable. Much good would be done to all fruit trees over ten years planted by soaking the ground well with liquid manure, choosing a fairly dry time in February, March, or even April. Apple trees cannot be renovated more quickly or cheaply than by supplies of liquid manure. From 50 to 100 gallons is not too much to give to a tree that has been planted for say fifteen years.—E. M.

#### EARLY PEARS.

THE early Pears that ripen in August are not very largely grown. They are soon past their best, and at that time many other delightful fruits are in season. If gathered and eaten at the right moment, however, these early Pears are delicious and refreshing. Their season may be extended by gathering them at intervals, and if stored a few days in a cool fruit room their flavour is considerably improved, provided, of course, that gathering takes place a little in advance of ripening.

**CITRON DES CARMES** is a well-known early variety, bearing abundant clusters of fruit after the manner shown in the illustration here given. In most seasons it bears freely, and succeeds either as a pyramid or a standard. The fruit when ripe is yellowish green in colour, and in forward seasons may be gathered about the third week in July.

**DOYENNE D'ETE** is the earliest summer Pear, ripening a few days in advance of the preceding. It is of delicious quality if eaten at the proper stage, but to secure it at its best the fruits must be gathered in advance of their ripening. If allowed to hang upon the tree till quite ripe the quality greatly deteriorates. The fruits are smaller than those of Citron des Carmes, but more yellow when ripe. It bears freely either in standard or pyramid form.

**JARGONELLE** is a popular early variety of much larger size. Its flesh is sweet, melting, and very juicy, the quality truly delicious. It is unsuitable for small gardens, not fruiting well as a pyramid, but in the standard form or trained on buildings with abundance of room for its spreading branches it is decidedly the best early Pear grown.

#### Forced Strawberry plants and exposure.

—It is often stated that, provided forced Strawberries are not exposed at the roots, they do not take any harm. But I am inclined to think we may carry this advice too far. This season a lot of plants for forcing protected with ashes did not break nearly so strongly as I could wish; the spikes were short and scarcely out of the foliage, whereas the same variety placed in fruit houses and not given much heat, only to keep out frost, was all one could desire. Again, we often see a very low temperature advised for young plants, but much depends upon when it is given. I had a lot of plants just showing their bloom in the centre of the plant, and through the breakdown of a boiler many have failed to fruit freely, though the temperature they were in never went

lower than 40°. Till this season I was under the impression Strawberry plants were not so particular as to exposure. Doubtless these, like many others, do not like extremes: and with regard to the first failure, when one can house the plants in cold fruit houses and keep well supplied with moisture, one is more independent, as he can get at them at any time. Failing houses, cold frames with ample protecting material are useful.—FORCER.

#### UNHEALTHY PEACH TREES.

OCCASIONALLY the most skilful Peach growers are troubled with trees that suddenly become unhealthy, the foliage assuming a pale green or yellowish colour, the growth weakly and followed by the fruit falling wholesale. What makes the mystery greater is the fact that other trees in the same house, or, if outside, on the

choking up the pores of the foliage after several applications. When this was discovered the tree was vigorously washed morning and evening with chilled water, and a dressing of muriate of potash given at the rate of 2 ozs. to each square yard of border as far as it was thought the roots extended. The result of this treatment was a rapid improvement in the health of the tree, and before the end of the season it was as vigorous as any other on the place and is now a mass of bloom. Sulphate of iron at the rate of a quarter of an ounce to the square yard has a very good effect in bringing a healthy hue to the trees on some soils, but is utterly useless here on our light soil. Muriate of potash answers better than any other remedy that I have tried. Another enemy to Peach and Nectarine trees is "blister," which usually attacks the foliage early in the season. A low temperature and cold winds are considered the principal cause of this dis-

*Pear Citron des Carmes. From a photograph sent by Mr. McWalter, Armagh.*

same wall, are perfectly healthy and everything that the cultivator could wish. Several probable causes have been mentioned from time to time that are likely to produce such an effect on the trees, but I think nothing really definite is known. One cause I believe is the roots taking up some element from the soil which, passing into the sap, cannot be assimilated, thereby injuriously affecting the growth. It is also a fact that such trees are the first to become infested by insect pests and the efforts to cull the enemies often produce a still further bad effect on the trees. As a case in point, last year I had a large tree outside of Hale's Early Peach the foliage of which began to lose colour, and directly this occurred aphids became very troublesome. A new insecticide that was highly recommended was freely used to eradicate the foe, but I believe if I had employed more clear water and less insecticide the tree would have recovered sooner, as many of the leaves fell through the oil or other substance in the insecticide

figurement to the trees, but I think there are other causes, such as the fungus remaining dormant on the trees for months, and again becoming active in the spring when fresh growth is made. In proof of this, we see trees lifted from outside walls and taken indoors become more or less blistered for a year or two. Some trees that I brought indoors last autumn have this spring had a few leaves on each affected. This was not caused by a low or fluctuating temperature. Probably the old remedy of picking off all the infested leaves and cutting away any malformed shoots as soon as detected is still the best, also spraying the trees thoroughly with an insecticide that is known to destroy fungoid attacks. Sulphide of potassium has always acted admirably with me for checking the spread of blister, mildew or any fungoid enemy on Peach trees. Half an ounce dissolved in 1 gallon of warm water is quite strong enough for the worst cases. After using this preparation for nine years I can strongly recommend it, but I

should state that under glass care should be exercised that none of the liquid falls on the paint or woodwork, thereby staining and disfiguring it. In addition to natural manures, I may advise an application of superphosphate at the rate of 2 ozs. to the square yard for either inside or outside trees, giving a dressing now and again as soon as the fruit has been gathered. This will do good on any soil, and materially benefit the trees and their produce.

W. G. C.

#### GROS COLMAN GRAPES.

UNDER the best cultural management, on a suitable soil, and every advantage that may be deemed desirable to grow this Grape well, it cannot be termed a variety of rich flavour, and on some soils and under conditions that other varieties like, Gros Colman is of a very objectionable quality, the disagreeable Ivy flavour being very pronounced—so much in fact, that it has been rejected by gentlemen as being unfit for their dessert tables. There can be no question that soil exercises a wonderful effect on this variety, that which is light, porous, and of a sandy warm character being the best adapted to its requirements. On the soil of the description mentioned I find it succeeds splendidly, and many experts have stated they never tasted the variety so free from the Ivy taint, and I could mention other places where the soil is similar having the same effect, particularly Mr. Child's, of Croome Court Gardens, Worcester-shire. For many years I have seen his exhibits at Cheltenham and other shows, and although the bunches were never large, the size of berry and high finish I have never seen surpassed, not even by Mr. Taylor, Alderman Chaffin's talented gardener, at Bath, who always grows this Grape in grand form, and whose soil is of the character named. On the other hand, I have not seen this Grape in perfect form when grown on a close, heavy soil; it may be that mortar rubble, sand, or other materials have been employed to render the compost suitable, the result has, so far as I have seen, been disappointing. The crop and size of bunch and berry may have left nothing to be desired, but the colour has always been more or less foxy and the flavour far from pleasant, in spite of cultural skill second to none. Opinions probably will never agree as to colour and quality going together, but although many say that a red berry is of quite as good a flavour as a deep black one, I think those who make the assertion would hesitate about doing so when referring to Gros Colman. Every year I have a few bunches at one end of theinery devoted to this variety that fail to finish up well, and which would furnish cause for complaint if sent to my employer's table, or if sold to the fruiterers who purchase our surplus Grapes. And a further proof of the value of a high finish is given by the fact of the annually increased demand for such Grapes in spite of increased competition and falling prices. To get this Grape in the best possible order and of superior flavour the Vines should be started at the latest early in March, as unless the colouring process is completed by the end of September it is very doubtful if they will finish properly unless October is a particularly bright and sunny month. In our uncertain climate it would be folly to start the Vines late on the expectation of a fine October giving the desired colour, it being just as likely to prove unfavourable as otherwise. On the question of temperature a good deal of difference of opinion exists, some advocating a warm, or, say, Muscat heat, and others a cooler temperature that would be suitable for Black Hamburgs or Alicante. My practice is on the later system, as obligation is no choice; the Gros Colman house being the lowest and least supplied with piping, a high temperature would be impossible, but even if plenty of heat were available I should not maintain a Muscat heat, a perfect finish being obtained without it, and this also means less expense in firing. It should be understood that while not recommending a high tempe-

rature fire-heat could be dispensed with in hot weather: on the contrary, I think it a great mistake to allow the fires to be out for days or weeks, depending entirely upon natural heat. There can be no doubt that a gentle heat in the pipes morning and evening is of material service by keeping the atmosphere sweet and pleasant to the Vines, also preventing great fluctuations of temperature, which cause mildew, checks, and other evils. Very often cases may be seen where a false economy has been made in trying to save expense in fuel, finding when too late that the extra cost of fuel would have been money well spent. Manuring is another matter of more than ordinary importance, which can only be settled by a close attention to soil, subsoil, and a knowledge of the constituents that are present or absent in the soil. If the grower on a heavy soil were to feed his Gros Colman or other Grapes in the same manner as another one that has to deal with a very light one, the chances are that he would kill his Vines with kindness. On our soil I apply stimulants in a weak form every time the borders are watered both summer and winter, but such a system would prove injurious on heavy and badly drained borders.

G. C. R.

## BOOKS.

### FERN GROWING.\*

FIFTY-THREE years of diligent research, as stated in the preface, have led the author to come to the conclusion that the great problem of Fern hybridising had at last been clearly and definitely solved by himself and by several of his pupils, some of whom, unfortunately, are no more. Unless one deliberately closes his eyes to the facts published in connection with British Ferns, it is difficult in the presence of the numerous instances stated by the veteran Fern grower, to whom we are indebted for the production of so many beautiful forms, to remain incredulous on the subject any longer, for the experiments of which the records are published leave very little doubt as to the success of the operation repeated by him times without number. Mr. E. J. Lowe states (p. 73) "that altogether more than nine hundred experimental sowings of spores have been made in forty years," so that his conclusions have not been drawn in any way hastily.

If we take into consideration the comparatively short space of time that has elapsed since the discovery of the reproductive organs in Ferns by a German botanist in 1834, it will be seen that the work done by the author of "Fern Growing" is exceptionally interesting, for, not satisfied with the publication of the results of his simple crossings of varieties or even of species, he also largely dwells on the possibility, nay, on the to him undoubted real effects produced by multiple crossing. This theory consists in the impregnation of several cells of one prothallus by the sperm of three, four or even six varieties, and as an example he gives, at page 64, the results of experiments having produced in some instances plants with two kinds of fronds in which the characters of the six parents were distinctly shown.

The experiments conducted by him with such signal success appear to be conclusive, yet they do not agree with similar ones carefully undertaken by me ten years ago under the guidance of Col. Jones, who narrowly for three years watched the results of the operation. This consisted in the sowing under his directions of four species and one variety of North American and British *Osmundas*, and the result was thousands of seedlings, all of which when fully developed represented one of the five plants sown, but though they were planted out and grown for three consecutive years, there was not the slightest variation observed among them. Yet, at p. 65, the

author, speaking of a series of experiments in which four parents had been used, states that "In these experiments no single individual was like any one of the varieties that had been sown together." The experiment has since been repeated by me, and has been, as before, attended with negative results. These two experiments, and others equally fruitless, having been worked on hardy exotic Ferns do not, however, affect Mr. Lowe's work, as I have had other opportunities of testing the efficacy of the theory of simple crossing, as stated in Lowe's "Fern Growing."

A very interesting operation and mode of propagation known as the sectioning or dividing of the prothalli into several parts as a means of increasing the seedlings is well described in this remarkable work; the same operation had already been successfully performed when a note of it appeared in THE GARDEN of February 27, 1886, p. 192, but this was in connection with the raising of *Todeas* only. Although dealing exclusively with native species and varieties, "Fern Growing" is unquestionably a work of great merit, full of established facts, clearly related, of useful hints as to cultivation, propagation and hybridisation, and should be in the hands of all who take any interest in that beautiful class of plants. It is a most valuable addition to "Our Native Ferns," "British and Exotic Ferns," &c., by the same author, as the reading is clear, concise, and well calculated to guide, encourage, and emulate Fern growers in their endeavours to produce new forms of British Ferns. The illustrations of many of the hybrids raised by the author of "Fern Growing" are numerous, and the whole work reflects the greatest credit upon author and publisher alike, and it is sincerely hoped that it will receive at the hands of the public the attention which it really deserves.

G. S.

### WAYSIDE IRELAND.\*

"WAYSIDE IRELAND" is the narrative of a trip from Cork through Connemara, Achill Island, &c. The author is not one of those who go from Dan to Beersheba and say that "all is barren." He is determined to be pleased, and he shows a keen sense of humour in recounting all that he sees. He chats with parsons, priests, peasants, "Removables," and in the facial lines of these last, be it said, he discovers a marked resemblance to the humble "bog-trotter" of the soil. At Kilkee from the railway-carriage window he notes "great huge blocks of Flag Iris and the Potato gardens blue with wild Scabious" and *Aster maritimus* quite at home, "one sheet of magenta." Cut, dried, and sold by the gross in bunches for decorative purposes, the French and Germans, he thinks, would make money by it. Barren Hill abounds in wild plants of great beauty; Ferns of all sorts and a blue *Campanula* in sheets of colour. Corkscrew Hill, too, is a "perfect paradise of wild gardening," and when you get down into the valley at the Ballyvaughan side, the entire aspect becomes so like the hills in the Holy Land, the plains where poor Jacob guarded his flock and had his vision of visions. Here *Fuchsia Riccartoni* is seen in full bloom, and "Hydrangeas quite blue from the iron in the soil. Dahlias live out all winter and become huge bushes of bloom." There are good oysters too. On Achill he saw *Parnassia palustris*, *Pinguicula*, quantities of *Sedum* and *Saxifrage*. The climate of Achill Island is so mild, that Dahlias live out all the winter at Dugort, the most northern portion, and so do *Fuchsia Riccartoni*, *Veronica*, *Escallonia macrantha*, &c. The book contains sixty-five pages of readable matter, and should have a wide circulation if only that it may perhaps induce the searcher after natural beauty to visit a portion of the Queen's dominions which has hitherto been much neglected by tourists.

## STOVE AND GREENHOUSE.

## THE FRAGILE HAREBELL.

(CAMPANULA FRAGILIS.)

THIS is one of the most charming of all the dwarf-growing members of the Bellflower family, of which there are several others some of which may possibly be hardier than that now under notice. This Harebell is seen to far better advantage as a basket plant or for brackets above the line of sight than for growing in lower positions. I have grown it with the best results for the latter purpose when having to fill brackets outstanding from a wall covered with glass overhead, but with open sides, a groundwork of climbers covering the wall itself. In its season it was here a most effective feature. It also serves a good purpose when used in quantity as marginal lines to large basket arrangements or the stages of conservatories, whereby the pots of other plants are conveniently hidden. As a window plant it is grown extensively in some parts of the country, finding equal favour with the humble cottager, the well-to-do artisan, and those of high degree. I recollect very well being shown on one occasion some plants of this Harebell by the gardener to a well-known family which were attended to by the lady of the household. When grown in a window it should be suspended no lower than the upper half. More light will thus fall upon it, this being essential to induce it to flower more profusely. Its growths will frequently reach far below the pot in which it is growing, continuing a long time in flower. It is a remarkably easy plant to propagate, division in the early spring being the better method of increase. In its culture the mistake that many make is that of over-potting. A smaller-sized pot with the soil made firmer will give the best results. The compost should consist chiefly of loam, with some pieces of lime rubble mixed with it, likewise a little decomposed leaf soil if available. A very fitting companion to this Harebell is *Campanula isophylla*, or the Ligurian Harebell, a most profuse-flowering and free-growing species. It has flowers somewhat larger than the subject so well depicted in the accompanying illustration. For rockwork outside in sunny spots both varieties can be relied upon to give every satisfaction. Another good old species is *C. garganica*, which is of closer growth, having darker coloured flowers than those of *C. fragilis*, which are of a soft shade of pale blue. These dwarf Campanulas are all natives of sunny Italy; hence it is not well to expose them entirely during our English winters.

SOUTHERN.

**Asclepias curassavica.**—This plant, which is referred to on p. 244, succeeds in an ordinary greenhouse temperature and is easily grown from seed sown in gentle heat. If the seed is sown in the early part of March, nice flowering plants can be had the same year, as the growth is rapid. Seed pods are freely borne, and when these approach the ripening stage the woolly-like covering over the seeds within the pods has a quaint, yet pleasing appearance.—E. M.

**Begonia Rajah.**—The different fine-foliaged Begonias, in the production of which *B. Rex* has played so conspicuous a part, are, I think, more grown than was the case a few years ago, and among them there are now some very beautiful forms, though most of the new varieties of this section come from the Continent. To the lover of *B. Rex* in its numerous forms the new *B. Rajah* will have much to commend it, for it is a decidedly pretty and very distinct Begonia, dense and compact, yet free in growth, and is as suit-

able as *B. Rex* for planting on rockwork or in similar positions. In this the major portion of the leaf is of a decided brown hue, while the course of the veins is marked with bright green. The under sides of the leaves are of a dull red colour. The surface of the leaf is somewhat puckered between the veins. It was discovered by Mr. H. M. Ridley, of the Botanic Gardens, Singapore, and has through that gentleman been introduced into this country. Being a native of the tropics, it requires the temperature of a stove, in which structure it will form a new and distinct feature. This Begonia was shown in good condition at a meeting of the Royal Horticultural Society last August, when a first-class certificate was awarded it.—H. P.

## CALADIUMS.

THE present-day culture of the *Caladium* affords an immense contrast to that of twenty-five or thirty years ago. Now we have a

temperature falls below 60° as an average, with 55° as the very lowest. With some growers it has been a practice as the plants become shabby to stand them out in vineries, so as to be clear of them in the stove. The penalty, however, has to be paid sooner or later; one season they may escape, but in the next they may possibly be left too long when the cold nights come on. No suspicion may be aroused until the following spring, when the question of shaking out for repotting is undertaken. If the bulbs be then found rotten throughout, it may be put down safely enough to the cold treatment during the autumn. I prefer to lay them on their sides under other stove plants when the pots are large. Some amount of moisture will reach them in this way; whereas if standing upright the pots might catch too much for the good of the bulbs. Another good plan—one which, all things considered, is the best—is to shake the bulbs out of the soil, clearing them carefully of

*Campanula fragilis.* From a photograph sent by Miss Burrowes, Moreton House, Buckingham.

number of varieties which possess the greatest diversity of colours in the richest possible shades; then we were confined to but a few really good sorts, not many of which are now found in gardens.

## CULTIVATION.

Caladiums are not in the slightest degree difficult plants to cultivate. Heat and moisture are the two chief essentials to success; given these, the rest of their treatment is easy. Where many fail, however, is in the treatment of the bulbs during the dormant period. More Caladiums have been lost by oversight at this time than during all the rest of the year put together. At no time, even when resting, should they be outside of the stove, whilst it is never desirable to let them remain in any position where the

their old roots and removing at the same time any decayed part round the base of the bulbs; then they should be covered with sand in seed-pans. To keep them entirely dry even then is a mistake; an occasional watering should be given to prevent the bulbs shrivelling. Dry rot will at times set in under the best of conditions, but it is greatly obviated by the bulbs being plunged in sand and watered occasionally. When the bulbs have been chilled, the decay is of a different character, being of a soft or soapy nature. Most of the Caladiums have been introduced from the district of Para—land drained by the Amazon and only a few hundred miles south of the equator. This fact at once speaks for itself as to the necessity of warmth when at rest even,

as it also does to the inadvisability of keeping them too dry. Coming from the valley of the Amazon points also (assuming that their habitat is congenial to them) to the fact that alluvial soil, rich in decaying vegetable matter, is the proper soil to choose, or at least to imitate as nearly as possible. In my own experience this has been borne out, for I find that the best of leaf-soil with a little good loam and road scrapings is as good a choice as can be made, two-thirds of leaf soil to one of loam being a good proportion. Failing good loam I have added old Mushroom-bed manure with excellent results. Firm potting is not needed, by this I mean ramming of the soil; all the work may be done with the hands unless it be a large plant, to which a shift is being given during its growth, then a potting-stick may be useful, but it should be used sparingly. It is far better to err on the side of small pots than to go to the other extreme, for *Caladiums* can be watered freely, being gross feeding plants. I do not care for artificial manures as stimulants, natural manures being much better, liquid farmyard manure or that made from good Peruvian guano being two good selections. I have frequently watered with the latter when the plants were infested with fly at the base of the leaf-stalks, with good results in exterminating this insect. Although *Caladiums* enjoy moisture in the atmosphere as well as at the roots, it is never advisable to wet the foliage overhead with the syringe, more particularly if the water be hard; it water-marks the leaves in the same way that it does bunches of Grapes. Shading is needful as the sun gains power. After the middle of March it should be the rule to shade from bright sunshine, but not heavily, the ordinary shading of a stove being sufficient at any time. The light-coloured varieties are seen to better advantage when shaded a little more than the others. When it is seen that the growth is ceasing, then far less water will be needed; a warm pit from that time would be a good place for them. Some kinds will push up several flower-spines after having formed a leaf or two in the spring; these should be pulled out in good time. The time of starting into growth can be regulated so as to suit each case, but, on the whole, the month of February is a good starting time. Starting in too much soil or, in other words, large pots, is a great mistake.

#### VARIETIES.

The following may be taken as a good selection of twenty-four kinds of various habits. To give colours is scarcely needed, seeing that so many catalogues give descriptive lists. As dwarf kinds, *C. argyrites*, *C. minus erubescens*, *C. Souvenir de Para*, and *C. Ibis Rose* are worthy of all that can be said in their favour; *Mme. Leon Say*, *Reine de Danmark*, *Raymond Lemoine*, *Comte de Germiny*, *John Laing*, *Marquis F. d'Albertus*, *Mrs. H. Veitch*, *Mons. Willaume*, *Mercedes d'Argent*, *L'Autonne*, *Comtesse de Brosse*, *Charlemagne*, *Cardinale*, *La Lorraine*, *Lymington*, *Louis A. van Houtte*, *Gaspard Crayer*, *Glück*, *Triomphe de l'Exposition*, and *Candidum*, one of the best light-coloured varieties. G.

**Impatiens Sultani.**—If this is raised from seed I do not see much good in sowing it before March is tolerably advanced. If sown much earlier the seed is apt to germinate badly and the young plants will often come to a standstill should the weather be very dull and cold in the early stage of their growth. This very attractive Balsam is of quick growth, and as comparatively few care to have larger specimens than can be produced in 6-inch or 7-inch pots, there is not the need for such early propagation as is the case

with plants of slower growth. In a temperature of from 60° to 70° this *Impatiens* will make rapid progress, a never-failing supply of warmth and atmospheric moisture being the important factors in its well-being. Cuttings strike with great freedom at this season, this being the method of increase generally followed. It is, however, advisable to have a plant or two in small pots for furnishing cuttings, larger specimens being apt to damp off in winter.—J. C. B.

### NOTES OF THE WEEK.

**Streptosolen Jamesoni** is a plant, I fear, not grown so extensively as it should be, for it is a gem for late winter and early spring flowering—a decidedly pretty combination of colours. The flowers keep well when cut and used for indoor decoration. It is of easy cultivation and will flower at almost any season, but is, I think, prettiest and most useful at the time named.—J. R., *The Gardens, Tany-bulch*.

**Bunch Primroses and the frost.**—Hardy as these are they suffered this year in our garden. In a long border near my cottage, facing west, many plants were killed, while those growing on a north border have not suffered in the least, the leafage being as good as last autumn. I note the common Primroses had all the foliage killed in many places. Wallflowers are all killed, in borders and on the stone walls round the abbey.—J. CROOK.

**Rhododendron Early Gem.**—In spite of the recent severe winter this *Rhododendron* about three weeks ago was in full bloom in the Coombe Wood nurseries of Messrs. J. Veitch and Sons, and is still in flower. This shows how hardy the shrub is, as many things have suffered greatly through the prolonged severe frost. The purplish colour of the flowers was very rich in contrast to the deep green glossy leafage.

**Hedera atropurpurea and the Forsythias.**—If one desires a pretty contrast of colour it can be got by planting these two things together. A few flower-laden shoots of the *Forsythia* spreading over the deep purple, almost chocolate-coloured leaves of the Ivy have a rich effect. This variety of the Ivy is not often seen, but it is very handsome, the leaves rich in colour and the growth vigorous.

**Rose Reine Marie Henriette.**—In our garden this Rose is not in the least injured. I planted a big plant from a pot some two years ago on a south wall. Last year it gave us some splendid blooms, and it promises well for this year. It is far hardier than many other Teas and climbing kinds growing by its side. *Catherine Mermet* and *Yellow Banksian* are sadly cut, while such kinds as *L'Idéal* are killed to the ground.—J. C., *Forle Abbey*.

**Daphne Genkwa.**—This, recently in bloom in a cold house at Coombe Wood, is a delightful shrub to force gently, as its clusters of rich lilac, almost violet-coloured flowers are distinct from other things in bloom at this season, and one desires as much change as possible in the greenhouse plants in spring. The flowers are fragrant, but not so much so as those of the *Mezereon*. *D. Genkwa* was brought by Fortune from Japan in 1866, but it is comparatively rare. When in the open it blooms usually at this time, and should have a sheltered corner.

**Magnolia stellata.**—The late frost has injured the evergreen *Magnolias* everywhere almost without exception, and often to such an extent that not a single green leaf is visible. But amidst the wholesale destruction wrought among shrubs by the exceptionally severe weather, *Magnolia stellata* has escaped. In the nurseries of Messrs. Veitch, Exeter, a specimen is just now in full bloom, presenting a beautiful sight. Although the plant is scarcely 4 feet in height, it is covered with more than fifty large snow-white blossoms. The plant is growing against a low wall with a western aspect. That it is perfectly hardy

without such protection is proved by another plant growing as a bush in a perfectly open and exposed position at Newton Abbot. This also is in full bloom at present, though it has not received the slightest shelter of any kind.—F. W. M.

**March rainfall in Wales.**—I presume the rainfall here (including snow) during March "beats the record" for even this humid district, for out of the thirty-one days we had but seven without rain in measurable quantity, and most of them were dull and sometimes foggy, so that the sunshine was almost nil. The total rainfall for the month was 8.31 inches, the greatest fall occurring on the 23rd, 1.36 inches. During the month we recorded rain exceeding an inch on three days, viz., 19th 1.18, 23rd 1.36, and 28th 1.03, so I think, taken altogether, we had enough.—J. R., *Merioneth*.

**Persian Cyclamens at Farnham Royal.**—We recently noticed a very fine collection of Persian Cyclamens in the nursery of Mr. James, Farnham Royal, near Slough. The colours were superb, especially the shades of crimson. A very fine variety had rose-pink flowers, another white flushed with pink, set off with a crimson base, whilst in another case they were white, one of the largest and purest white forms we have ever seen. One sees so many objectionable magenta and allied tones in the flowers of the Persian Cyclamen, that it is delightful to see such care taken to get the clearest and brightest self.

**Notes from Baden-Baden.**—One of the prettiest sights in my garden is just now a bed of *Anemone blanda scythica*. It comes from North Kurdistan, and is distinct from the type and *blanda cypriana*. One-tenth of the plants has pale or sky blue flowers, nine-tenths are of the purest white. It is quite a treat to look at these white stars. There are several forms of *Muscari azureum*, *M. a. Freynianum* being the best. The spikes are two to three times as large as in the typical form, and of the same or even a brighter turquoise-blue colour. A new *Fritillaria* is very striking. It grows 5 inches or 6 inches high, and the flowers, as large as a hen's egg, are of a deep claret-red, inside tessellated white. *Iris mesopotamica* is a fine novelty. The flowers are much like those of *I. sindjarensis*, but they are broader, fuller, and of a pleasing milk-white colour with a sulphur-yellow crest.—MAX LEHTLIN, *Baden-Baden*.

**Camellia reticulata.**—It is unfortunate that this fine *Camellia* is not more plentiful, for although it was introduced about 1820, it is only to be found in a few places in England. We have a fine plant on the conservatory wall. It has been in bloom for some time, and will be for a considerable time yet; the flowers are semi-double, large, over 7 inches across, of a glowing pinkish crimson, and frilled. This *Camellia* is quite distinct from all the other singles or doubles, its flowers being free from the stiff form of the single cup-shaped or the double imbricated formal flower. A large plant of this *Camellia* would be most effective in bush form if planted out in a large house along with such as *Donkelaari*, the *Old Double White*, and many more that could be named of equal merit. Such a house would be most attractive when the *Camellias* were in bloom during the dull winter months, particularly in such a winter as we have lately had.—A. KEMP, *Coolhurst, Horsham*.

**Forsythias.**—The bright yellow of the flowers of these Japanese shrubs, their profusion, and the exceeding grace with which they are displayed make the *Forsythias* amongst the most welcome of all our spring flowering shrubs. There are two species, *F. suspensa* (or *Fortunei*), *F. viridissima*, and a hybrid between them called *intermedia*. *F. suspensa* is the first to flower, and is easily recognised by its lax habit. The hybrid follows, and lastly *viridissima*, although so closely that all three may be seen in flower at one time. The last named is a shrub of more sturdy, erect habit. To get a fine effect these *Forsythias* should be planted in large masses and be given if possible a background of some evergreen like the *Box* or *Holly*. They can be struck from cuttings

or layers so finely, that it is very easy to obtain a good stock.

**Asparagus plumosus.**—No better illustration of the value of this species as a climbing plant can be needed than that afforded at Mr. Icton's nursery, Putney Park Lane. It is there grown in large quantities, not only for cutting, but also for the purpose of seeding, so as to meet the large demand for seed, which is the only reliable mode of increase other than by division. On a recent visit I was greatly struck with the excessive vigour of the plants, which are being grown in borders rather than in pots. Several young shoots were pushing up that were quite as large as the average lead pencil. Mr. Icton had for experiment cooked some of these, and found them to possess the true *Asparagus* flavour. In one house the growths were so dense as to envelop the under side in a complete shade. A temperate treatment is found to answer well. Considering its durability in a cut state, this *Asparagus* is not even now grown in sufficiently large quantities; of its utility there can be no manner of question.—H. G.

**Franciscea Hopeana.**—It is not often that one now meets with this species—an old one it is quite true, but none the less welcome. I noted it quite recently flowering in the stove show house at Messrs. Veitch and Sons', Chelsea. Compared with most of the *Franciscea*s this variety has smaller flowers, but this is more than compensated for in their great profusion, extending over a long season, one crop often succeeding another in rapid succession upon the merest bit of wood. The flowers, which are deliciously scented, open at first of a light violet shade, gradually fading away to pure white with age. In the more favoured districts of the south this *Franciscea* may be stood outside to mature its growths after completion of growth, then when again introduced into warmth it will soon yield a crop of bloom. Being a somewhat slow-growing plant, it remains for a long time of a convenient size. In a cut state it is admirably suited for making button-hole bouquets. It is also known under the specific name of *F. uniflora* and is one of the oldest species in cultivation.—J. HUNSON.

**Orchids from Edinburgh.**—I am sending you per this post a few blooms of Orchids. A bloom of *Cattleya* which I send seems to be near to *C. intermedia*, but it has this year a much stronger bulb, more like that of *C. amethystoglossa*. It is 18 inches in length, with three leaves, as against two in former years. The larger bloom of *Cattleya Trianae* is rather over, but the smaller, which is not quite developed, being from a very small bulb, which ought not to have been allowed to bloom, but was overlooked, shows fairly well the colour of the larger flower; it is a very fair variety. I send three vars. of *Vanda tricolor*, two vars. of *V. insignis*, *V. suavis* Veitchi, *Dendrobium Venus*, *D. japonicum*, two blooms of *D. Ainsworthi*, a few *D. nobile* vars. and *D. Wardianum*, *Cypripedium villosum aureum*, *Cattleya Skinneri*, *Odontoglossum Rossi majus* varieties, *O. crispum*, *Laelia anceps*, *Cymbidium Lowianum*, and *Coeloglyne sparsa*.—H. J. JAMES HUNTER, Edinburgh.

\*\* A beautiful gathering of Orchids, the flowers carefully packed and fresh. The *Cattleya* sent is *C. intermedia*. The flower of *Cypripedium villosum aureum* is that of a very fine variety.—Ed.

**Notes from Paris.**—The season is very late this year. *Anemone nemorosa* is coming into bloom in the woods round about Paris. In the St. Germain Forest the ground appears in the distance as if covered with a white sheet of bloom. Here and there some flowers of the blue *Pulmonaria officinalis* are appearing. In the garden *Omphalodes verna* is opening its Forget-me-not-like blue flowers along with the yellow *Doronicum caucasicum*. *Primula denticulata* and *P. cortusoides amona* are showing their first blooms. These have not suffered in the least from the severe winter, although the thermometer in February for several days registered as low as

20° centigrade. A plant of *Aralia (Fatsia) japonica*, quite unprotected in the border and planted out years since, had its leaves slightly injured by frost and snow, but the wood is quite safe. It is a general idea amongst gardeners here that these Japan *Aralias* are not hardy. In the same border I have a dozen plants of *Musa Basjoo*, the north Japan Banana tree, a native of Hakodate, in the Isle of Yezo. These were planted out four years ago and slightly protected in winter with dry leaves. All of these are now starting into growth. The Horse Chestnuts are unfolding their leaves (April 15).—J. SALLIER.

**Rhododendron arboreum.**—The value of this shrub for large conservatories and winter gardens is by no means so fully taken advantage of as it might be, for there are few if any plants that produce at this season so bright and glowing a mass of colour as it does. In the typical form the flowers, of a brilliant red, are produced in rounded, cone-shaped trusses about 4 inches or 5 inches through, resting on a rosette-like whorl of dark green leaves. It is, however, an extremely variable species, and the different varieties have flowers ranging in colour from the brilliant red just mentioned to rose and pure white. One of the best of the rosy-flowered varieties, *nilagiricum*, has been figured in THE GARDEN, July 20, 1889. There is, besides this, another variety called *limbatum*, a fine specimen of which is in bloom in the temperate house at Kew, and which has flowers very similar to those of *nilagiricum*, but its leaves, instead of being rusty coloured beneath, are silvery grey. Where these *Rhododendrons* cannot be grown out of doors (and it is only in the south and south-western counties that the climate is mild enough for that), a house with sufficient fire heat to maintain a temperature above freezing point in the severest weather and which is kept moist and well ventilated in summer is best suited to them. *R. arboreum* is the oldest Himalayan species in cultivation, having been introduced in 1820.

**Rhododendron fulgens.**—The brightest flowered of hardy shrubs at this season is unmistakably *Rhododendron fulgens*. Whilst the various trees and shrubs belonging to the great rosaceous family—the Plums, Almonds, Peaches, &c.—give us whites and pinks in abundance, and the Forsythias provide shining masses of yellow, the only real red is this *Rhododendron*. In the dell which at Kew is devoted to these shrubs there is a plant of *R. fulgens* some 7 feet high. It rarely misses flowering. That after such a winter as the past it should be uninjured in foliage and now have a flower-truss on almost every twig speaks well for its hardiness, even though sheltered by trees from north and east. The flowers are of a rich blood-red, each about 1½ inches across, and the whole compact, rounded truss 3 inches to 4 inches in diameter. The species is a native of the Sikkim Himalayas at an altitude of 12,000 feet to 14,000 feet, and Sir J. Hooker, who introduced it in 1851, says that it is "one of the richest ornaments of those inhospitable regions, the flowers glowing like fire in the short hours of morning sunlight." In foliage it resembles *R. campanulatum*, another Himalayan species also in flower. In both instances the leaves are covered beneath with a reddish felt; the flowers of *R. campanulatum*, however, are white. Other *Rhododendrons* in flower at Kew are *dauricum*, purple; *Nobleanum*, rosy red, and *præcox*, pale rosy purple.

**Notes from Wales.**—So wintry an aspect of all vegetation in the middle of April in this district is happily of rare occurrence. All plants are wearing their winter garb; consequently there is but little bloom in the open. A few *Rhododendrons* of one variety only—supposed to be Cunningham's White—are the most conspicuous flowering objects on the place. *Prunus Pissardi* is showing colour, a few varieties of *Berberis* are just opening, and *Andromeda floribunda* has not yet expanded. There is no *Laurustinus*, for all the bloom buds were killed. Daffodils on grass are developing, early and late varieties

having a neck-and-neck race, so all will be in bloom together. Primroses and Polyanthuses, the pretty wood Anemones and the modest Violets combined add brightness and sweetness to our sunny banks, while patches of *Andromeda axillaris* are even now attractive. Our rocks are still devoid of much floral beauty. A few *Erica carnea*—white and pink—*Daphne Mezereum*, a clump of *Hepaticas* here and there, mostly *triloba*, *Chionodoxas*, an occasional sprig of *Omphalodes verna*, some of the earlier Saxifrages, the old double yellow Wallflower—a rare plant now-a-days—and some Anemones, exceedingly bright, are about the sum total of flowering plants thereon. Of damage done by the extremely severe and prolonged winter, followed by excessive rainfall, I hope to report on later, when one can reckon the losses more accurately than at present, for while the destructive easterly winds now prevailing remain, it is risky to jump at conclusions.—J. R., Merioneth.

**Royal Horticultural Society.**—The next meeting of the Royal Horticultural Society will be held in the Drill Hall, James Street, Westminster, on Tuesday, April 23. In addition to the society's ordinary show, the National Auricula and Primula Society will hold its annual show. At 2.30 p.m. a conference on Primulas and Auriculas will be held in the hall. Professor Michael Foster, F.R.S., has promised to preside, and the following papers will be read: "New Primulas," by Mr. J. G. Baker, F.R.S., &c.; "Culture, Classification, &c., of Primulas," by Mr. Selge-Leonard; and "The Auricula," by Mr. J. Douglas. The council will be glad of exhibits of as many different natural species of Primula as possible.

**Hardy fruit growing.**—The council of the Royal Horticultural Society of Great Britain offer a prize of £10 for the best essay on "The Commercial Aspect of Hardy Fruit Growing in the United Kingdom." The essay, not to exceed 10,000 words, is to be sent under seal to the secretary of the society, 117, Victoria Street, Westminster, on or before August 1, 1895, each essay to be signed with a motto and the writer's real name and address enclosed in a sealed envelope bearing the same motto outside, the prize essay to become the sole property of the council of the society to deal with in any way they may think fit. Unsuccessful essays will be returned after October 1, 1895, on application, enclosing the necessary postage and the motto of the writer.

**The weather in West Herts.**—During the past week the nights have been, as a rule, cold, but on several days the temperature has risen above the average for the time of year during the warmest part of the day. On the 17th the highest reading in shade was 64°, whereas on the night preceding the 14th the exposed thermometer showed 7° of frost. There was a slight fall of rain on Tuesday night, otherwise this was a dry week. There has been a capital record of sunshine during the past eight days, the average duration for this period amounting to nearly nine hours a day. A Peach tree trained to a south wall in my garden came first into blossom on the 4th, which is a week later than its average date for the previous nine years and thirty-one days later than last year. The wood Anemone first flowered on the 10th inst., or eleven days later than in the same wood last year. The swallow first made its appearance at the Watereress beds here on March 28—an unusually early date.—E. M., Berkhamsted.

**Cobbett's Gardening.**—Will any reader kindly tell me the date of the first edition of this work?—X.

**The New Zealand Veronicas.**—Will any reader who grows the New Zealand Veronicas kindly tell me how they have fared after the past severe winter?—H.

**Books received.**—"Beeton's All About Gardening," New and enlarged edition. "Fruit Growers' Association, Ontario," twenty-sixth annual report. "Agricultural Gazette of New South Wales."

# “NEW EASY” LAWN MOWER.

Lightest Running and Cheapest ROLLER MACHINE,  
THE LARGEST SIZE (24-in.) EASILY WORKED BY ONE MAN.

**UNEXCELLED DURABILITY!**  
MADE IN ALL SIZES FROM 10 TO 24 INCHES.

**Unsolicited Testimonials.**

Trelissick, Truro,  
"March 4, 1895.  
"Gentlemen,—Twelve years ago I purchased the first 'Easy' Lawn Mower. Since then I have had several machines from you, and it is only due to you that I should tell you how entirely satisfactory they have all proved. I have for several years worked two of your 24 in. machines fastened together, drawn by a mule, and it is astonishing the amount of work they got over. In my opinion the 'New Easy' is the most easy draught, the simplest, and cheapest Lawn Mower extant. "WM. SANOWIN."

**Unsolicited Testimonials.**

"Churwell, Leeds,  
"August, 1894.  
"I have 'New Easy' Lawn Mower, pattern 1888, which I got from you in 1889. This is the sixth season, the machine has worked well (18-in.), and has cut 1/2 acre Lawn weekly by a lad since I got it, and it is good now "SAMUEL ATKINSON."  
"Biggar, August 29, 1894.  
"Gentlemen,—The 'Easy' Lawn Mower I got from you seven or eight years ago has been a splendid machine. "ROBERT BOA"  
"The Gardens, Ravelston, Black Hall, Midlothian, March 5, 1895.  
"All the three machines I have had are working still, the first having been purchased seven years ago. I have not used any other for three years, as the men find them light and easy to work, as we have a very large extent of grass to keep, and the 'New Easy' are fine running machines, with rollers in front. "D. JARDINE."

"The Gardens, Laleham House, Staines.  
"June, 1894.  
"Gentlemen,—We have had 'The Easy' now for six years, and it has done its work well, and easily worked by our man. I sharpen it once or twice a year, otherwise it has never been out of use, and never wanted repair. "THOS. ANDERSON."

PRICE LISTS MAY BE OBTAINED THROUGH MOST IRONMONGERS AND SEEDSMEN OR FROM

**SELIG, SONNENTHAL & CO.,**  
85, QUEEN VICTORIA STREET, and LAMBETH HILL, LONDON, E.C.

## THE CELEBRATED XL ALL VAPORISING FUMIGATOR

The Cheapest, Most Simple, and Best Fumigator in existence. A Liquid Compound simply Evaporated from a Small Copper Cup by the Agency of a Spirit Lamp.  
Prepared in Bond, from Duty-Free Tobacco, by Special Permission of the Hon. Board of H.M. Customs.  
\*\* One trial will convince anyone of its great superiority over all other Fumigators.

**COMPOUND**

For using in the Fumigators.

**FUMIGATORS**

(Will last for Years).

To do 5000 cubic feet of space at a time, 2s. each.  
To do 2000 cubic feet, 1s 9d. each.  
Showing a cost for Fumigating of only 8d. per thousand cubic feet of space.

Mr. A. Maxin, The Gardens, Heckfield Place, Winchfield, writes April 16, 1895: "Your XL ALL Fumigator is far and away the best contrivance I have ever used or seen, and I feel sure that no one will ever return to the use of Tobacco Paper after once testing your XL ALL Vaporising Fumigator."  
This Fumigator is largely used by Messrs. J. Veitch & Sons at Chelsea; Messrs. F. Sander & Co., St. Albans; Messrs. Low & Co., Clapton; Mr. William Bull, Chelsea; Messrs. Charlsworth & Co., Bradford; Mr. Thomas Rochford, Turnford; and also by most of the other large Nurserymen and leading Gardeners throughout the United Kingdom.  
To be had from all Nurserymen, Seedsmen, Florists and Seedsmen; or direct from the Sole Proprietor. Price List Post Free.

## LLOYD'S PERFECTED ‘Pennsylvania’

AMERICAN  
LAWN-MOWER.

"We strongly recommend the 'Pennsylvania.'" —Field.

World's Fair, Chicago, Highest Award.  
Paris International Exhibition, Highest Award, Silver Medal.  
NO AWARD WAS GIVEN to any English or Continental-made Lawn Mowers.

**THE “PENNSYLVANIA”**  
IS THE  
Perfection of EASY WORKING and EFFICIENCY.

The only American Lawn Mower fitted with Six Cutting Blades.

## THE “PENNSYLVANIA”

IS THE

**MACHINE**

FOR  
GOLF  
LINKS.

Above illustration shows the machine as it appears when OUT OF GEAR, and in the proper position for running it easily from one place to another, over gravel walks or rough and uneven ground. When moving it in this way, there is no unnecessary wear of the driving pinions, all risk of damaging the cutting knives is avoided, and the machine can be pushed over the ground with very little labour—a great advantage in extensive gardens, but especially on GOLF LINKS.

**THE “PENNSYLVANIA.”**  
CARRIAGE PAID TO ALL STATIONS.  
**THE “PENNSYLVANIA.”**  
ONE MONTH'S FREE TRIAL ALLOWED.

**TESTIMONIAL.**

"World's Columbian Exposition, Chicago, Oct. 16, 1893.  
"Gentlemen,—I desire to state that we have used the 'Pennsylvania' Lawn Mowers almost exclusively during the progress of the Fair, with the most satisfactory results. The ease in working them was remarkable, and they did more work than we supposed was possible for Lawn Mowers to accomplish. The appearance and condition of our lawns in comparison with others prove the high grade and superiority of these Lawn Mowers.—A. B. FARQUHAR, Executive Commissioner."

Price Lists and Testimonials (including the New Pony Machine) from

And all Ironmongers and Seedsmen.

# NEW PLANT CATALOGUE (No. 133) for 1895

## WM. CLIBRAN & SON

WILL BE PLEASED TO SEND THEIR

New Catalogue of Stove and Greenhouse Plants, Herbaceous Plants, Soft-Wooded Plants, Tea Roses, Dahlias, Hardy Climbers, Florists' Flowers, &c., &c.,

Post free for Three Stamps. 152 pages, with full descriptions of all the finest novelties and the best old varieties of the above-named plants.

OLDFIELD NURSERIES, ALTRINCHAM; ALSO AT MANCHESTER AND LLANDUDNO JUNCTION.

# JAPANESE LILIES

Special reduced prices to clear an immense consignment just come to hand direct from Yokohama, Japan.

GENUINE, PLUMP, WELL-RIPENED BULBS FRESH FROM THE JAPANESE CASES.

Satisfaction absolutely guaranteed to every purchaser. We supply most of the large gardens in England and on the Continent.

## LILIUM AURATUM.

Splendid bulbs, up to 9 in. round, 12, 2s.; 50, 6s. 6j. (The above will bear 4 to 6 flowers each.)

Grand bulbs, 9 to 10 in. round, 12, 3s. 3d.; 50, 10s. (No small included in above.)

Extra-size bulbs, 6s. doz.; 50, 20s. Gigantic bulbs, 12s. doz. Finest possible condition. Half dozens at dozen rate.

Postage 9d. per doz., 6d. per half dozen EXTRA. Fifties, uniform rate of 1s. extra for carriage.

Japanese Drawings of Lilies in book form. An edition de luxe, specially drawn in colours by a very eminent Japanese artist. Each variety faithfully portrayed from Nature. Flowers and leaves are full natural size. 36 varieties are depicted in handsome Japanese cover. Limited number only for sale. Price 10s. 6d. A genuine work of art. SENT ON APPROVAL TO CUSTOMERS.

## W. H. HUDSON, F.R.H.S.

Japanese Lily Importer,

KILBURN, LONDON, N.W.

Telegraphic Address: "Auratum, London." SPECIAL LILY LIST FREE

# CHRYSANTHEMUMS

SPECIAL OFFER. SUPERPLUS PLANTS, EXTRA STRONG.

Mlle. T. Rey, Jules Ferry, Pitcher and Manda, Mrs. J. R. Hammill, Autumn Tints, Good Gracious, Duke of York, Pres. Borel, Mrs. S. Fortescue, Mrs. Geo. Gordon, Wilfred Marshall, Mad. C. Capitant, Mons. C. Molin, W. Bolla, Eugene Daille-douze, Elmer D. Smith, Mrs. G. Addison, Inter-Ocean, Dr H. Hull, Mons. Thos. Hallyer, and many other choice novelties. Purchaser's selection, 6s. dozen, post free. W. J. G.'s selection, 7s. Not less than a dozen sent.

Older Varieties, but good, at 3s. 6d. dozen.

"PHILADELPHIA," the startling American Novelty, strong plants, 2s. 6d. each.

## W. J. GODFREY, EXMOUTH, DEVON.

## WHOLESALE SEED CATALOGUE.

We have now published our Wholesale Catalogue of

# Vegetable and Flower Seeds

Containing also the best Novelties of the Season. MAY BE HAD ON APPLICATION. Any of our Customers not having received one by post will oblige by letting us know, when another shall at once be posted.

Watkins & Simpson, Bulb and Seed Merchants, EXETER ST., STRAND, LONDON, W.C. Seed and Trial Grounds—Feltham and Twickenham, Middlesex.

## THE NEW STRAWBERRY. — Stevens'

Wonder. The most prolific and finest Strawberry grown. Solid fruit, good flavour, high perfume. Awarded First-class Certificates Royal Hort. Society and Royal Bot. Society, 1895. See *Gardener's Chronicle*, March 2, *Journal of Horticulture*, March 14, and *THE GARDEN*, March 16. Good rooted runners, £3 per 100; established in 3-in. pots, £5 per 100. Plants ready early in August. Terms cash with order. Orders in rotation. Stock limited.—J. R. STEVENS, Clayton Nursery, Hassoeks.

FILL your Greenhouses, Gardens, &c.—RICHARD PANNETT, Florist, Chailey, Sussex, offers choicest Zonal Pelargoniums, double, single and Ivy-leaf, 100 cuttings in 100 varieties, 8s.; do. well rooted, 20s. per 100 varieties; Dahlias, well rooted, 12 choice varieties for 2s.; 100 do. 20s. See Catalogue also for Fuchsias.

# DICKSONS' IRISH ROSES.

NEW

## ALEX. DICKSON & SONS

Have pleasure in announcing for distribution in May a further series of their

## Celebrated Pedigree Roses,

HELYN KELLER (H.P.), Rosy Cerise, superb ... 10 6 each  
MAVOURNEEN (H.P.), Silvery Flesh, first rate ... 10 6  
MAFJORIE (H.T.), White, Pink centre, very pretty 7 6

ALSO

The Best of the NEW FRENCH and BRITISH ROSES. Descriptive Catalogue Post Free on application.

## NEW (H.T.) ROSE

BELLE SIEBRECHT (Mrs. W. J. Grant).

Raised by Alex. Dickson & Sons, distributed by Siebrecht and Wauley, New York. The most valuable introduction of the past ten years. This superb variety has gained the highest awards whenever exhibited in Great Britain and America, chief among these being the National Rose Society's Gold Medal. Valuable alike for exhibition, decorative and forcing purposes. No frost-tender, however small, complete without it.

PLANTS IN POTS IN MAY, 10s. 6d. each.

Particulars Post Free on application to

## ALEX. DICKSON & SONS ROYAL NURSERIES,

NEWTOWNARDS, Co. DOWN, SOLE AGENTS FOR EUROPE.

## JACK FROST

Has caused many losses that can be made good in an easy and cheap manner by purchasing the following bulbs and plants, which I can strongly recommend as being first class.

### BEGONIAS, Single.

20,000 grand bulbs, mixed colours, finest offered at the price, 3s. per dozen.

### PELARGONIUMS, Show and Decorative.

Five plants, in best kinds, 6s., 9s., and 12s. per dozen.

### ZONAL PELARGONIUMS.

Best kinds only, 6 for 2s. 6d.; 12 for 4s.

### IVY-LEAF PELARGONIUMS.

A very choice lot, 6 for 2s. 6d.; 12 for 4s.

### DOUBLE PETUNIAS.

Extra fine new kinds, 6 for 3s. 6d.; 12 for 6s.

SEND FOR CATALOGUE, FREE.

## H. J. JONES,

Ryecroft Nursery, Hither Green, LEWISHAM.

## NETTING FOR TENNIS BORDERING.

Good colour and specially prepared, with line attached on net, top and bottom throughout; easy to erect or to take down; 25 yards long, 3 yards wide, for 7s. 6d., carriage paid.—H. J. JONES, Net Works, Rye.

# DANIELS BROS.

TOWN CLOSE NURSERIES,

## NORWICH.

## TUBEROUS-ROOTED BEGONIAS.

(CARRIAGE FREE)

We have much pleasure in offering fine Flowering Tubers from our grand strains, as below:—

**Double-flowered** Per doz.  
Choice named varieties, including some magnificent flowers ... 35s., 40s. and 50s.  
Extra Choice varieties for Exhibition, carefully selected, a grand mixture ... 24s. and 30s.  
For Pot Culture, splendid varieties of the most beautiful form and colours ... 12s. and 18s.  
Mixed Doubles for Bedding, a capital variety of good double flowers. Per 100, 40s. ... 6s.

**Single-flowered**  
Extra Choice Exhibition varieties, immense blooms of the most beautiful colours and perfect form ... 18s.  
For Greenhouse and Conservatory, a very choice mixture of carefully selected flowers ... 9s. and 12s.  
For Pot culture, beautiful selected varieties. Per 100, 40s. ... 6s.  
Choice mixed Seedlings, all selected, and approved flowers, splendid for bedding. Per 100, 25s. ... 3s 6d.  
From Mr. R. G. MILNE, Gardener to the Earl of Minto.

Aug. 2.

"I am glad to say the BEGONIAS have done splendidly; they are by far the best strain we have. They were greatly admired by all who saw them."

From Sir R. Dick CUNYNGHAM, Bart., Cheltenham. Oct. 6.

"On my return home, after a long absence, I am much pleased to find the bed of nearly 400 BEGONIAS still full of flowers. The double ones in the house are a show for colour, size and beauty of shape."

## Fruit Trees a Speciality.

APPLES, Pears, Plums and all kinds of hardy fruit trees. The best varieties for garden or market. New and rare sorts not obtainable elsewhere.

STRAWBERRIES, Gooseberries, Currants, and all kinds of small fruits. All the best, newest, and most profitable varieties.

Priced and abridged Catalogue free. Full Descriptive Catalogue and Guide, the most complete issued, 6d.

JOHN WATKINS,

POMONA FARM NURSERIES, WITTINGTON, HEREFORD.

## CARNATIONS.

The best new and old varieties now ready for planting out in all the classes. 31 First-class Certificates in 1894 awarded to J. Douglas for Carnations. 1st prize Auriculas, show and alpine to name. Carnation and Picotee seed, saved from best named varieties, hand fertilised, 2s. to 3s. 6d. per packet. Auricula seed, only the best, 1s. 6d. to 2s. 6d. per packet. Fancy Primrose and Polyanthus, 1s. to 2s. 6d. per packet. Calceolaria seed (Douglas's best strain), 1s. 6d. to 2s. 6d. per packet, Silver Medal R.B.S., 1894. Cineraria (Douglas strain), 1s. to 2s. 6d. packet, from 1st prize named varieties in 1894-5. R.B.S. Catalogue gratis and post free on application.—JAS. DOUGLAS, Great Bookham, Surrey.

# FERNS A SPECIALITY.

We have an immense stock of all kinds of Ferns, Stove, Greenhouse, Fibry, Hardy Exotic, and British, including many very beautiful varieties rarely seen, but which ought to be more generally grown. Catalogue free on application.

W. & J. BIRKENHEAD, F.R.H.S. Fern Nurseries, SALE, near MANCHESTER.

No. 1223. SATURDAY, April 27, 1895. Vol. XLVII.

"This is an Art  
Which does merd Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare*.

## ORCHIDS.

### NOTES ON PHALÆNOPSISIDS.

THE long cold winter has been very trying to these beautiful Orchids, and the effect of the low temperatures which prevailed is in many places too apparent. Nothing is more annoying than to grow a fine plant, to nurse it as carefully through the winter as circumstances permit, only to find it in spring rapidly decreasing in size by the loss of the lower leaves, yet this is unfortunately the position of many growers just now. Failures should have their advantages as well as disadvantages, and may often point out useful lessons for future guidance. The present is a suitable time for a thorough overhauling, cleaning, repotting or surfacing of these Orchids, the temperature now being sufficiently high to prevent checking the plants, they also having the best of the growing season before them. It is hardly necessary to say that, unless it is absolutely unavoidable, Phalænopsisids ought not to be disturbed at the roots, but baskets and cylinders will decay; composts, however carefully prepared, eventually lose that sweet, open condition so necessary to the well-being of the roots, and the cultivator must step in to prevent the backward tendency that this entails. The best way to provide a new rooting medium for the plants and to transfer them to it will be the first consideration. It has been my experience that Phalænopsisids of the stronger growing kinds, as *P. amabilis* and *P. Schilleriana*, transplant much better from pots or pans than from baskets or cylinders, because of the freer ramification of the roots among the drainage. A root running straight down the rod of a cylinder for a foot or 15 inches is all very well as long as the wood lasts, but when the time arrives for moving the plants it will be found very difficult to do so without damaging them considerably. With pots or pans, on the other hand, no matter how firmly the roots have taken to the sides, we have only to carefully break them, pick or wash away all loose pieces of potsherds and dead roots, while those with living roots clinging to them may be placed in the new pots. This, too, sounds easier to do than it will be found in practice, but with care it may be done without checking the plants. Against the use of pots I have to urge the undoubted liking that the roots of Phalænopsisids have for wood and the length of time they live upon it. Taking into consideration the rapidity with which this decays in the heat and moisture of the East India house, I am inclined to prefer pots for these more robust growing kinds, using blocks and pans for the weaker growing species. The pots used may be deep rather than broad, those with perforated sides being preferable, the free circulation of air about the roots being conducive to their longevity. The greatest care is needed in placing the plants in their new pots to avoid bruising the roots, pot-tery ballast being preferable to broken pots as drainage for this reason. This may be brought right up to the base of the plants, kept higher in the middle, and the plants secured as firmly as may be before putting the layer of Sphagnum on. This must consist entirely of clean growing points and must be kept alive, being in this state a capital index to the moisture in the pot.

In transferring plants from old to new baskets even greater care and judgment are needed. The first thing necessary is to wash away all the Moss and remove all the old crocks that can easily be got at. A fine toothed saw such as is used by carpenters for dove-tailing should be used for severing the rods in as many places as needed to pull the basket to pieces, avoiding the roots where these are clinging to them. Here the rods may have a thick strip cut off with a sharp strong knife, making no attempt to detach the roots, but placing the strips in the new baskets, filling up around the base of the plants with large pieces of charcoal, fixing so that they cannot slip about, or the roots cannot obtain a hold of them. The mode of transferring block plants has recently been referred to in THE GARDEN, and a little care in this operation is amply repaid in the results attained. The whole of the plants after being disturbed should be subjected to a kind of convalescent treatment, a little more heat and shade being afforded for a time and the plants kept in a nice moist temperature. It is not advisable to damp the foliage much, but a slight sprinkling on bright days will be beneficial. A suitable night temperature will now be 60° to 65°, rising by fire-heat on dull days to 75°, by sun-heat running up to 85°, increasing the air as the plants re-establish themselves and inuring them by degrees to a stronger light. If flower-spikes appear before the plants have taken a hold of their new home, it is a good plan to restrict the number of flowers upon them, but not to entirely remove the spikes, as this may possibly cause secondary ones to be produced, the plants being proportionately weakened. H. R.

**Cypripedium selligerum atro-rubens.**—*C. selligerum* was raised in the nurseries of Messrs. Veitch and Sons some seventeen or eighteen years ago. *C. selligerum atro-rubens*, although not so stately as the variety *majus*, is of grand form and, as the name implies, of fine colour, the veining in the dorsal sepal being rich rosy purple and the petals also nicely suffused. The parents of this variety are *C. barbatum* × *C. philippinense*.—W. H. G.

**Lælio-Cattleya Pallas superba.**—This beautiful hybrid from Mr. T. Statter's collection is one of exceptional merit. It is the result of crossing *Lælia crispata* with *Cattleya Dowiana*. The sepals and petals are both pale rose, the side lobes of the lip being rather deeper in colour than the other segments, whilst the large front lobe is beautifully crisped and of an intense rich violet-purple, faintly veined in the throat with yellow.—W.

**Odontoglossum polyxanthum** (Hardy's variety).—This very beautiful and distinct variety of this fine species was shown by the gentleman whose name it bears at the recent meeting at the Drill Hall. The sepals and petals are broadly lanceolate, of a lemon-yellow ground colour, the former blotched and the latter spotted with very dark cinnamon-brown; the lip is broad and flat, of a chocolate colour, excepting a small space at the base, and a fringe at the apex, both of which are pure white.—W. H. G.

**Cymbidium eburneum.**—"W.," writing of this beautiful Orchid at page 229, says it first flowered in this country about seventeen years ago. This is an error; it was flowered in Messrs. Loddiges' nursery in 1847 and was figured in the *Botanical Register* in that year. It flowered again in the Hackney Nurseries the following year, May, 1848, and a drawing was prepared from it for the "Magazine of Botany." The plant was introduced from the Khasya Hills in 1837 by Griffiths, and therefore it did not flower for ten years after its introduction. The first variety that flowered had no spots, but varieties with the lip more or less spotted are found in importations. The temperature in which the plant ought to be grown and its other cultural requirements are now

well understood, and when once the plant is well established its culture is not at all difficult. It will not thrive in peat, and although some good growers use a little peat in the compost it is not necessary. The main part of the potting material should be good loam, although of this all kinds are not suitable. That in which I have found it do best is found on commons where the Brackens thrive. Tough fibrous material, decayed sufficiently to kill the grass, is what the plant delights in. I have tried them with a third part of loam to one of peat, and they have done equally well in either. The use of Sphagnum with the compost may or may not be desirable; it is certainly not necessary. A good proportion of crocks is certainly beneficial and has the effect of keeping the compost open for two years. After that time repotting is necessary.—J. DOUGLAS.

**Dendrobium Phalænopsis Schroederianum.**—With the increased temperature and light this splendid species will be growing rapidly, producing growths not only from the base of the pseudo-bulbs, but also towards the tops. These latter growths are very useful for propagating, and young plants raised from them grow away with great vigour when once established. If taken off too soon, however, they are not always satisfactory, and even if taken with a portion of the old bulb attached—as, in fact, they should be, they are often a long time before they make any headway. In a letter from a friend, who is very successful with Orchids and an enthusiast in their culture, he says that he has had very good results by placing small pans in juxtaposition to the new growths, these being elevated for the purpose on stakes or otherwise and filled with compost in the ordinary way. This allows the growths to root and establish themselves before being removed from the parent bulb. The advantage will be obvious to anyone, and I should say the results would amply repay the little trouble involved. It would possibly be necessary to enlarge the holes in the bottom of the pans in order to pass them over the bulbs and growths, this being preferable to splitting the pot, as in the old-fashioned plan of ringing Crotons and other plants. My correspondent says the difference between plants raised in this way and any other with which he is acquainted is surprising, much time being saved, as they are not checked in any way, but grow in a perfectly natural manner from the first.—R.

**Cattleya Lawrenceana.**—This grand *Cattleya* is one of the finest introductions of late years. This plant produces its spikes of bloom from March until May. The flowers are usually of a rich rosy purple, the lip shaded with maroon-purple; there are, however, several lighter coloured varieties, but the darker forms are decidedly the more beautiful. This superb *Cattleya* grows in abundance in British Guiana at about 3000 feet to 4000 feet altitude upon the branches of trees in sheltered positions.—W.

**Dendrobium capillipes.**—On a recent visit to Messrs. Lewis and Co.'s nursery at Southgate I saw a fine example completely covered with flowers deep golden yellow throughout, and produced singly and in pairs on peduncles that just reach above the leaves. Thus a good-sized well-flowered plant upon a raft, as was the specimen referred to, has the appearance of a dense mass of yellow colour. It is found in Moulmein, and was imported about thirty years ago by Messrs. Low and Co., of Clapton.—G.

**Spathoglottis aurea.**—Of the few species comprised in this genus, this is the most useful and beautiful. It was introduced by Messrs. Veitch some fifty-five years ago from Mount Ophir, a mountain in Malacca, but it appears to have been lost to cultivation or to have become an exceedingly scarce plant, and remained so until re-introduced about ten years since by Mr. Sander, of St. Albans. Being a terrestrial Orchid, it should be potted in a good mixture of turfy loam, fibrous peat, and silver sand, with the addition of some chopped Sphagnum, plenty of drainage being given. This plant should be grown in the East India house.

The flowers are produced upon an erect scape, from 2 feet to 3 feet high, and a succession is kept up for several weeks. The individual blooms are 3 inches in diameter, the sepals and petals of a bright canary yellow, the former striped on the outer surface with red; the lip is also clear yellow, streaked with chestnut-red and spotted with the same colour on the basal portion.—H.

**Cattleya Schroederæ.**—This somewhat resembles the popular *C. Trianae*, and flowers about the same time. Mr. Joseph Broome, of Llandudno, sends me some beautiful flowers, each measuring fully 7 inches across, the colour very delicate, whilst the orange-red throat of the lip is very pronounced. An albino is also included, and although this is the best white form I have yet seen of *C. Schroederæ*, it cannot be called pure white, as there is a decided tint of blush in the lip; the bloom is of fine size and good substance, with very broad petals, the lip large, beautifully fimbriated, and broadly expanded, with much less orange-yellow in the throat than is found in the coloured varieties. It is certainly a chaste and beautiful form.—W.

**Cypripedium Morganii langleyense.**—Although *C. Morganii* is one of the very finest hybrids in this genus that have yet been raised, the variety *langleyense* is much superior to the original form, as may be supposed, seeing that the finest varieties of the parent plants have been used. This is a cross between *C. Stonei platyanium* and *C. superbium*. This variety is superior to the original in having larger, broader, and better defined petals, and the whole flower is richer in colour. This, like the type, was raised by Messrs. Veitch and Sons, and I believe flowered for the first time about twelve months ago.—G.

#### BARKERIAS.

There are but few species in this genus, which was established by Knowles and Westcott. Recent authorities have included them with *Epilendium*; nevertheless, they are still known in our gardens under the above name. It is a pity that these plants are not more extensively grown, for their requirements are few and they do not occupy a great amount of space. *Barkerias* are all natives of Central America, where they grow upon the branches of trees in Mexico, Costa Rica and Guatemala. The best way to treat them under cultivation is to place them upon blocks of wood without any soil round their roots. Many have failed with *Barkerias*, owing to keeping them too dry and giving too much heat, the most suitable temperature being similar to that maintained for the Mexican *Lælias*, where they can obtain a plentiful supply of fresh air and sunshine, both these being essential. *Barkerias* enjoy being frequently syringed, and during the summer months need very little or no fire heat. They are compact-growing plants with slender pseudobulbs, and being deciduous, lose their foliage during the resting season, at which time very little water will be required. The flowers, produced at different times during the year and continuing a long time in perfection, are borne on stems rising from the top of the bulbs. The following are the most beautiful, and well merit a place in every collection:—

**B. CYCLOTELLA.**—A very pretty kind, introduced from Mexico about fifteen or sixteen years ago, is often classed as a variety of *B. Lindleyana*. It blooms in the early months of the year, producing terminal racemes of very showy flowers, each measuring about 2 inches across. The sepals and petals are of a bright magenta purple, as is also the lip, excepting the disc, which is white.

**B. CENTREI.**—A fine form and very showy, introduced in 1873 from Costa Rica by Messrs. Veitch and Sons. The flowers of this plant often measure quite 3 inches across, the sepals and petals being bright rose, the lip white, tipped with rich

purple. The slender peduncle carries eighteen to twenty flowers upon a raceme.

**B. BARKERIOLA.**—This is a very small-growing species, not attaining more than about 3 inches in height and not so attractive as many of the other kinds. The peduncle bears three or four white flowers, suffused with a lilac tint, the tip of the lip being bright purple. This pretty little plant was introduced by Mr. F. Sander, of St. Albans, about 1884, and does better with rather cooler treatment than most of the others.

**B. ELEGANS.**—It was upon this plant that the genus was founded, having been introduced to cultivation by Mr. Barker in 1837 from Mexico. Although the first kind known, it still remains one of the best. For many years it remained a very scarce plant. The flower-stems are each about 18 inches long, terminating in a raceme of five or six blooms, which individually measure upwards of 2 inches across, the sepals and petals rich purple, suffused with white; the lip white, with a large purple blotch on the front.

**B. LINDLEYANA.**—A very beautiful species, often bearing from eighteen to two dozen flowers upon a raceme. These, appearing about September and October, are rosy purple, the lip having a large white disc. It is a very distinct and desirable species, growing about a foot in height, with leaves from 4 inches to 5 inches long. It was discovered by Mr. Ure-Skinner in Costa Rica, and first flowered in this country with Mr. Bateman about fifty-five years ago.

**B. MELANOCALON.**—This is a very distinct and rare kind. The flowers, produced freely, are of a rosy lilac colour, the lip having a blotch of green in the centre. It appears to have first been seen in bloom nearly fifty years ago, when it was described by the late Prof. Reichenbach.

**B. SPECTABILIS.**—One of the finest in the genus, although known in our gardens for many years. It flowered first in the gardens of the Royal Horticultural Society at Chiswick in 1842, but is at the present time seldom met with. The flowers are 3 inches or more across, of a rosy lilac colour, and spotted with red. It is a native of Mexico and Guatemala.

**B. SKINNERI.**—This, at the present time a rare plant, flowers during the winter months. It inhabits the same countries as the preceding kind at considerable altitudes, and was first sent home by Mr. Ure-Skinner. The flowers, produced freely, are bright rosy purple, excepting the lip, which is orange-red, with streaks of yellow on the disc.

*Barkerias* during late years appear to have lost public favour, but they are certainly worth the attention of cultivators, and those who have the accommodation for the Mexican species of *Lælias* should again take up their culture.

WM. HUGH GOWER.

**Dendrobium atro-violaceum (Ashby).**—This, I believe, has been in commerce for five or six years, having been introduced by Messrs. Veitch and Sons from New Guinea. It is a beautiful *Dendrobe* and quite distinct from other kinds. The flowers are produced on the leafless stems in pairs and threes. The sepals and petals are greenish yellow with deep purplish spots, and the lip is of a rich purplish colour. It is a very beautiful species, allied to *D. macrophyllum*, and requires strong heat to grow it successfully.—W.

**Odontoglossum triumphans.**—I am in receipt of two forms of this fine *Odontoglossum*. That from Mr. James Miller is of large size and beautifully coloured, the sepals heavily blotched with deep cinnamon-brown, the petals golden yellow, with smaller blotches and bars of a similar shade to those on the petals. The lip, white and finely fringed, has a large square spot of a reddish brown on the anterior portion, whilst the raised crest is very prominent. The other flower sent by "L. O. L." is similar, but the segments are not so broad. This species is one of our finest cool house kinds. It is very showy when in flower, producing an erect spike from 2 feet to 3 feet in length,

the individual blooms measuring 3 inches and more across. It is a native of New Grenada, where it grows at a considerable elevation on the mountains.—W. G.

**Angræcum Sanderianum.**—I have recently noticed this in several collections, and in some instances quite small plants have carried a couple of long, drooping spikes each with sixteen and eighteen blooms. It is a native of the Comoro Islands, and therefore enjoys strong heat under cultivation. The plants are naturally small, the narrowly oblong foliage not growing larger than about 6 inches, whilst the spike often measures three times that length. The pure white blossoms are each an inch across, the slender spur, which is also pure white, being upwards of 3 inches long. This plant much resembles *A. modestum*, but is distinguishable even when not in flower by having larger and broader leaves.—G.

**Celogyne lentiginosa (Ashby).**—All the kinds in this section produce their blooms on pendulous racemes, and are therefore better accommodated in shallow pans or wooden baskets, so that they may be suspended from the roof. This position not only suits their requirements by enabling them to obtain as much light as possible, but the flowers are seen to better advantage. This plant, a native of Moulmein, has flowers with straw-yellow sepals and petals, the lip being yellowish brown, margined with white, the side lobes also white, spotted with brown.—W.

**Cypripedium Lindleyanum.**—This is a strong-growing plant, the leaves attaining a length of 2 feet, and upwards of 3 inches broad. From such strong growths one would expect a fine large bloom, but this is not the case, for the flowers do not measure more than about 2½ inches across, and are borne on very long scapes. These are of a pale greenish colour, with red-brown veins, the lip of a similar shade, but somewhat darker. It succeeds well in a comparatively cool temperature, and is a native of British Guiana, where it is found at an elevation of about 6000 feet.—G.

**Cattleya Trianae at Southgate.**—Amongst a splendid lot of this useful spring flowering *Cattleya* that is now quite gay in the nurseries of Messrs. Lewis and Co., of Southgate, are some very beautiful varieties, ranging in colour from white to very deep purplish crimson. *C. T. splendens*, a fine large flower of very rich colour, especially the lip, which is beautifully frilled; *C. T. alba*, the delicate and chaste white variety, having only the yellow on the disc; *C. T. plumosa*, *C. T. Lewisiana*, both exceedingly fine and handsome; *C. T. delicata*, with white blooms of good substance, slightly flushed with rose; *C. T. quadricolor*, also very distinct, with large orange blotches in the throat, the front portion of the lip very bright and margined with white, are worthy of note. I noted also in flower some fine pieces of *Cypripedium callosum* in good variety, *C. Exul*, *Lælia harpophylla*, *Vanda tricolor* *Lewisiana*, very distinct, *Odontoglossum Pescatorei*, *O. cirrhosum*, *O. luteo-purpureum*, *Ada aurantiaca*, &c.—W. H. G.

#### SHORT NOTES.—ORCHIDS.

**Lælia purpurata.**—I have a plant of *Lælia purpurata* in flower. It has three fine blooms on one spike, the centre one having four sepals and two perfect lips. Is this unusual with this *Orchid*?—Gus. TROLLIE, *Rosebank, Cape Town*.

**Dendrobium Auguste Victoræ.**—This appears to be very free-flowering and grows to a good height. The blooms are pure white, the lip prettily veined with a pale violet hue, the sepals and petals having a peculiar twist. It was introduced by Messrs. Sander and Co., of St. Albans.—W.

**Orchids from Trewyn.**—I am sending you a few more *Orchids*. *Cattleya Mendeli* I bought in 1892, when imported. It is now showing eight sheaths, two flowers from each sheath. *Dendrobium fimbriatum oculatum*, two flowers of which I am sending, was bought in March, 1890. It has always bloomed well and is in fine flower at the present time.—J. C. WILLIAMS.

## WATER GARDEN IN NEW JERSEY.

THE illustration shows what we call over here a remarkably fine plant of *Victoria regia*. This specimen had twenty leaves in different stages of growth above water, a fine flower and two buds. The seed was started in the greenhouse early in March. The plant was moved to the outdoor pond about the middle of May, from which time till July 4 it had the protection of a sash. The sash and frame were then removed. The first flower opened July 14, and was followed by thirty others in succession, the last one opening October 4. Four flowers were permitted to mature seed, yielding respectively 188, 458, 293, and 569 large, plump, heavy seeds. Unfortunately, three of the young leaves were injured by a severe thunderstorm which passed over this district a few days before the picture was made. The nature of the damage shows plainly on the edges of the leaves. Many of the leaves were 6 feet in diameter, with rims 6 inches high. Will this plant compare favourably with good specimens grown under glass in

length and the leaf 42 inches in breadth. This was by 6 inches larger than any leaf I had previously measured. In my opinion the *N. speciosum* bears the handsomest flower that grows, everything considered.

*Clifton, New Jersey.*

S. C. NASH.

## KITCHEN GARDEN

## EARLY MILAN TURNIPS.

FEW can successfully force Turnips under glass, and in heavy clay soils many are afraid to sow early, as the plant runs and much time is wasted. The soil in most gardens this season worked splendidly and there was no difficulty in sowing in March for an early crop in the open, so that with a scarcity of vegetables in spring a few early dishes of Milan Turnips will prove most acceptable. From several years' experience I have found the Milan varieties the

vegetables force more readily. A few dishes of forced Turnips during April are a welcome addition to the somewhat meagre supply of vegetables at this season. Too much heat at the start must be avoided. I prefer to get the bottom-heat from leaves, these giving a slow, but moist heat, and the plants do not run to top. Allow a free circulation of air by the top ventilators or sashes. It is essential to sow thinly and to make a firm bed to assist the plants to bulb freely, as if the soil is too light the plants dry badly and make long useless roots. Moisture is important, and when the plants are growing freely they are much benefited by liquid manure. It is surprising what a lot of useful roots a good-sized three-light frame will produce. Seed sown the first week in February on a mild hotbed will give good roots the middle of April. A depth of 6 inches of soil is necessary, adding burnt wood ashes, bone-meal, or decayed manure if at all stiff or clayey.

For early dishes from the open a warm corner must be chosen. There are few better materials than wood ashes, burnt garden refuse, or the siftings from the potting bench. The more rapid the early growth the less danger of running, and in a light porous soil one can feed freely when the plants have made the third or rough leaf. For outside culture I still rely upon the Early Milan types. Last season these varieties sown on a sheltered border early in March were fit for use the third week in May. Much can be done to forward an early crop by using Bracken or straw hurdles as a shelter at the start. I do not shelter those sown in the open, as the frame roots give us a supply till the early crop on a warm border comes in, but those who do not force may with advantage give shelter in the early stages, and a week or two may be gained by sheltering with branches of Fir of any kind to break the force of cold east winds. For summer use I do not recommend the above varieties; there are better, such as Snowball and Red Globe, the value of the Milan being earliness. If the weather at the end of May or early in June be hot and dry, I find it advisable to lift fully-grown roots and lay them in soil in a cool border.

G. WYTHES.

*A water garden in New Jersey. Engraved for THE GARDEN from a photograph sent by Mr. S. C. Nash, Clifton, New Jersey, U.S.A.*

England? I have often stood on leaves to satisfy doubting visitors. The heaviest person I ever photographed on an unsupported leaf weighed 174 lbs.; add weight of rack (9 lbs.) made of laths, and placed on the top of the leaf to distribute the pressure and protect the web of the leaf from the sharp shoe heels. The total weight was in that case 183 lbs. I vouch for the absolute accuracy of these statements.

I have nearly all the varieties of *Nymphaeas*, or have had them, both hardy and tender. Some I have discarded as not worth bothering with. The only one that proved too much for me was *N. sphaerocarpa* (the Swedish Pink Lily). I have paid as high as 32s. for a small root of this species or variety, but though I have tried several times, I have not succeeded as yet.

*Nelumbium speciosum* does grandly here out of doors. A neighbour of mine planted one tuber of this in a natural pond (about 1¼ acres extent) in 1892. I visited this pond last year in August, and do not hesitate to say there were more than 1000 blooms and buds in sight. At my request he cut the largest leaf we could see. The stem measured 10 feet 6 inches in

best for early use, either for forcing under glass or for a first crop in the open. For some seasons previous to the advent of Early Milan I grew the Early Munich, a purple top variety, somewhat similar to the Purple Milan, but taking a longer time to mature and not so good for sowing under glass. Now there is a white Milan variety, a counterpart of the purple form, but even earlier. Sown under glass in the last week in January the new white variety was fit for table in ten weeks. Many may consider ten weeks a long time, but we had during that period several weeks of very severe weather, so that it was impossible to open the frames, and the plants were a great portion of the time in darkness. I find the Purple-topped Milan quite a week later, and in future I shall depend upon the Early White for sowing under glass, but its earliness may have been owing to position of the beds, one variety having received more warmth than the other. For crops in the open these varieties may be relied upon not to bolt like later kinds. Turnips do well forced if due attention be given in the way of moisture and a free circulation of air; indeed, few

**Tomato Ladybird.**—I believe this medium-sized, handsome fruited variety will take a leading position generally. One grower for market recently told me that he had a high opinion of it, having grown it last season. He preferred it to Hathaway's Excelsior, which had been his sheet anchor for many years and always sold well in the market. Ladybird is not only of good shape and quality, but a prodigious cropper also.—J. C.

**Runner Beans.**—These are rather uncertain if sown early in the open ground, the seed being so liable to rot. For an early picking the best way is to sow in boxes or pans, as advised for French Beans. If sown thinly and brought on in a cool frame they transplant well and soon make rapid progress. When planting a moderate drill should be drawn out, this being filled with light, friable soil, or if this cannot be done, some of a similar compost should be placed on and around the roots at planting time. Sutton's Scarlet is a good early sort, having an especially robust constitution and cropping well, the pods remaining in eatable condition longer than in some varieties. The old Scarlet for general use will still hold its own, well-ripened seed of this variety not being so liable to rot as the larger seeding sorts. Veitch's Climbing is another excellent Bean, which should be grown by everyone, Painted Lady or

York and Lancaster being capital for successional sowings. As a rule the first week in May is soon enough, even in warm sheltered gardens, for sowing Runners in open quarters. Do not bury the seed too deep, rather draw up a little soil round the stems when the plants are a few inches high. The climbing French Beans lately introduced are most useful, especially where difficulty is experienced in obtaining tall stakes which are needed for the ordinary Scarlet Runners. This new type of Bean does not as a rule run higher than from 4 feet to 6 feet, ordinary Pea rods answering well for supporting the haulm. Those who have not given this new type of Bean a trial should by all means do so. If these are sown at this date in the open ground, I would advise forming slight ridges and sowing therein in order to prevent the seed from decaying.—J. C.

**Potato Ringleader.**—I think it was Mr. Molyneux, of Swanmore Park, who, in replying to notes of mine on early Potatoes last year, advised me to give Ringleader a trial for early frame and border work. I took the hint, and do not regret it, as tubers planted in frames the second week in February are now (the same date in April) affording good eatable Potatoes, this having been accomplished in anything but the best of weather. Mr. Molyneux, if I remember correctly, placed it before Sharpe's Victor for earliness and general cropping, and I quite think he was warranted in doing so. Sharpe's Victor will not succeed in all soils. I tried it for two seasons both in frames and on an early border, but the yield was so poor that I did away with it. I fancy it requires a somewhat strong soil.—J. C.

**Sowing Peas in pots.**—The advocates of sowing the seed in pots and planting out the seedlings when 4 inches high have so far the best of the argument this season. For weeks the ground was frost-bound when we should have been sowing the early varieties. By doing so in pots in a cool house the plants grew strongly, and were ready to go out of doors into their permanent quarters as early as the seed could safely be transferred to the soil. Thus a fortnight would be gained, and that is of some consequence in the matter of early Peas. I every year sow a good batch of Duke of Albany in pots, keeping the plants in a cool house or frame. In this way I get good pickings of this Pea early in July. It is not safe to sow seed of the large Marrowfat varieties much before April, at least in heavy, cold, wet soil.—E. M.

**Tomato Early Ruby.**—This, one of the newer varieties I tried last year, is quite distinct. Last season was one of the worst on record for Tomatoes in the open, and though I had some half dozen kinds planted out, there was not sufficient warmth to give a fair test. Under glass this variety did well, the plants bearing enormous crops. It is one of the most prolific varieties I have grown. The fruits are nearly round, quite smooth, and of a rich ruby-red colour, in large clusters, many having ten to twelve fruits in a bunch, and most of them above medium size. The plants fruit freely quite close to the pot or soil, and for pots few varieties can equal the Early Ruby. Plants raised in March had ripe fruit in June.—S. H.

**Profitable Cucumbers.**—Varieties of Cucumbers are so numerous now-a-days that amateurs and others are often puzzled to know which to select from the long list which appears in the seed catalogues. Probably where profit alone is considered, a good strain of Telegraph is hard to beat, but for private gardens where quantity is not the sole object there are several other sorts of great merit. For some years I have grown one called Perpetual Bearer and can recommend it to all who prefer a large, handsome Cucumber. It is a capital bearer and, as its name implies, continues to fruit over a long period. Sutton's Prize-winner is also a grand white-spined fruit of fine symmetry and colour, and carrying a dense bloom. Allan's Favourite finds favour with many, being one of the best exhibition Cucumbers in cultivation. For general excellence that well-known

sort Tender and True would be hard to beat, although it is not everyone who can grow it satisfactorily, as it needs careful cultivation. Daniels' Duke of Edinburgh, although, perhaps, a little coarse, is a long, handsome fruit and a prodigious cropper. The Duke is very suitable for frame culture. The Roebford, a market variety now being catalogued by some as a new Cucumber, but which is not really so, it having been grown by some firms in the neighbourhood of London for some years, is just the sort for amateurs and those who have little space at command, as it will grow when pinched rigidly and fruit at every joint. Of the smaller-fruited section, Lockie's Perfection, Verdant Green, and Purley Park Hero are amongst the best, while for winter work the old Syon House is about the best when obtained true.—J. C.

**Savoy De Vertus.**—Late Savoys are always more useful than the early or small kinds, and in few seasons have large growers who have good quarters of late Savoys had better returns, as during the severe frost in February Savoy Cabbages were plentiful. Savoys are often sown much too early, as when they come into use in September or October there is such a wealth of Coleworts, Cauliflowers and other vegetables that the Savoy is not so much valued. The variety named De Vertus is well worth extended culture on account of its good keeping qualities. It may be termed an improved Drumhead. When sown at the end of April or early in May and planted out of the seed bed before the plants get drawn or weak it is a splendid winter Cabbage.—S. H. B.

**Cottager's Kale.**—Here this has stood the winter better than any; in fact it seems to stand with impunity any kind of weather. By some this Kale is looked upon as too common a vegetable to grow, but our plants, over a yard high, are giving abundance of succulent, mildly flavoured sprouts. The main point in the culture of this and other Kales is to sow early and ensure a free and strong growth by the end of September. It is useless to expect the plants to be serviceable in March and April if the growth is not completed by the time named. That which is made later is immature, and therefore unfitted to withstand the frost. I never cut off the heads of the plants until just before they begin to run to seed, as these afford much protection during the winter.—S. P.

**Forcing Beetroot.**—With the improved types of Turnip-rooted Beet there is no difficulty in providing the table all the year round with roots of first-rate quality. The stored roots at this season will grow out and lose flavour, but a check may be given by removing to a north border and covering with damp soil, thus keeping up a supply. When there is a scarcity it generally occurs through May, when the old roots are exhausted and the newly sown will be some weeks before they are fit for use. This may be overcome by sowing a box of seed in heat in the same way as Cauliflowers, pricking off when large enough singly into 3-inch pots, growing in frames, and when hardened off planting out on a sheltered border at the end of April. The plants soon bulb and are large enough for use in a short time. The best varieties for this purpose are the Turnip-rooted kinds.—G. W. S.

**Dwarf Brussels Sprouts.**—Many large growers do not care for dwarf Brussels Sprouts, and I can fully understand the reason if they supply the market, as size is everything. For late use and for home consumption I certainly advise a dwarf variety, as in our case this season the taller kinds were quite killed; whereas dwarf ones, though much browned, were sound and gave a lot of sprouts. For late use I do not advise early sowing; April is quite soon enough. The most important point in culture is ample space in the seed-bed, planting out early before the plants get drawn. If the plants of many of the Brassica tribe were given more space in the seed-bed and less delay in planting out, there would be hardier plants. I am aware these crops

often follow Potatoes or other early vegetables, and the ground is not vacant at the time. In such cases it is well to thin or transplant, and thus get strong plants. I will only name two varieties, as they are the most reliable, being dwarf, hardy, and valuable on account of their mild flavour. My selection is Sutton's Dwarf Gem and Paris Market, the former invaluable for spring use, and the Paris Market for early winter. Paris Market is much grown near Paris on account of the earliness of its hard, bullet-like sprouts and its compact growth, combined with good flavour. Being a dwarf grower it may be planted at 2 feet to 2½ feet apart in the row. This latter variety will supply the table from November till February, when the Dwarf Gem will continue the supply well into April. For earlier supplies, those who require this vegetable may obtain sprouts fit for table in September by sowing in a frame and transplanting when ready. For early use these dwarf growers are equally good, as they soon mature and the sprouts are not so strong when cooked.—G. WYTIES.

**Frame Cucumbers.**—Plants raised in March may now be planted out in frames, provided substantial linings are provided and the frames are well covered at eventide. Of course a comfortable bottom heat, the result of a bed of leaves well trodden, is necessary, taking care not to plant until all rank steam, if there be any, has dispersed. Place the soil, which should be light and sustaining, in a ridge in the frame some days before planting that it may become thoroughly warm. Make the plants firm, water home with tepid water, keep close until established, shading slightly if flagging occurs, and air carefully for the next month. Close early and syringe lightly on fine afternoons. Amateurs and others who have no means of raising their own plants can at this season always procure them of local nurserymen at moderate charges. Where seed has now to be sown for frame plants, Duke of Edinburgh, Lockie's Perfection, and Perpetual Bearer are all first-rate sorts for the purpose.—C.

**Dwarf Beans sown early.**—Many growers who have a heavy clay soil are placed in an awkward position in sowing seeds for early produce, as, should the season be unfavourable, the crop is much injured by cold in its early stages. To assist the germination of the Bean warmth is necessary, and even after the plants are above ground in wet, clayey soils they frequently turn yellow and refuse to grow, later sowings, with more warmth in the soil, overtaking them. To assist early rooting I have tried various ways. The best plan I found was to throw out the crude or cold soil, making a deep-shaped drill or trench, filling this entirely with spent Mushroom manure, the drill being several inches lower than the surrounding soil. In this the seeds soon germinate, and once the plants start into growth the manure greatly assists them.—S. H. B.

**Early Cauliflowers.**—Having tried several varieties for early summer use, I find Early London one of the best. I always sow in the autumn, sometimes wintering the plants in pots, and at other times pricking them out in a frame, using nothing but straw hurdles for winter protection in the place of lights. Plants raised in the autumn are much hardier than those obtained by sowing in heat in February. The plants so treated are now growing nicely on a west border. Each was planted under protection, as it were, by digging the soil out with a fork as planting proceeded, banking it up on the north side. Others in deep drills between the Asparagus beds also look promising. These autumn-sown plants are not nearly so liable to be eaten off by slugs as those of spring growth.—E. M.

**Protecting early Potatoes.**—Unless the growths of early Potatoes are protected in some way or other at night the probability is that they will be ruined. On open quarters I always use 9-inch or 10-inch flower-pots, these being stood between the rows during the day. It is advisable also to stop the holes in the bottom with clay, or this cavity will admit sufficient frost to blacken

the tops. Dry Braeken or short Oat straw also answers the purpose, although somewhat untidy in appearance. I like to give protection as soon as growth begins to force the soil in an upward direction; I am then on the safe side. The tender haulm can be preserved from frost for a few days—if other work is pressing—by drawing a slight mound of soil over each stool with the hoe, but partial protection is useless, and if once the first growth falls a victim, no secondary growth can produce tubers of a satisfactory character.—J. C.

## ORCHARD AND FRUIT GARDEN.

### RIBSTON PIPPIN APPLE.

PROBABLY no dessert Apple is so well known as this old favourite and more universally grown. Unfortunately, the tree is prone to canker in all parts of the kingdom, and many able men have an idea that the variety is worn out, and that it is only a question of time for it to go out of cultivation. Several of these pessimists who have seen our trees and the large and beautifully coloured fruit they produce

branches, healthy appearance, and fine fruit. Provided there is a free outlet for surplus water and a fairly warm and good soil, I believe that anyone may succeed in growing this splendid Apple to perfection. Where it fails under such conditions, it proves that some constituent necessary for the growth and general health of the trees is lacking. What that particular constituent may be can only be discovered after a series of careful experiments, and then applied as may be deemed advisable. I would also suggest the application of the wash mentioned during the winter, as I think it exercises a powerful influence for good on the trees. Another point worthy of increased attention is the stock upon which Ribston Pippin answers the best. Double grafting undoubtedly produces an excellent effect, employing a strong growing variety of the Warner's King stamp as the stock. Some trees that I saw on a strong soil in this county (Herefordshire) were wonderfully clean and healthy, without a sign of any ailment. Probably much more might with advantage be done in that respect where the above variety is pretty much a failure now.

While advocating the growing of Ribston

*Apple Ribston Pippin. From a photograph sent by Mr. Norman Blake, Bedford.*

have altered their opinions, and I believe this excellent Apple will continue to maintain its popularity in the future in spite of its propensities to canker. The cause of canker is such a debateable subject, that it will be unsafe to enter into that matter now, but I have proved that cankered trees of Ribston Pippin may be practically cured of that disease, more especially if planted on a light, porous soil. About six years ago I found canker setting in somewhat severely on about 200 trees, and I was afraid our Ribstons were doomed; the roots were all near the surface, and so far as one could see the trees (bush form) ought to succeed admirably. After experimenting with various chemical manures to supply a missing element in the soil, muriate of potash appeared to have answered the requirements. At first only  $1\frac{1}{2}$  cwt. per acre was applied, but since then double that quantity has been used with the most pleasing results. In addition to this fertiliser at the roots, each winter the trees have been thoroughly washed with 1 lb. of crude potash and 1 lb. of caustic soda dissolved in 10 gallons of water. Since adopting the above measures our Ribston Pippin trees have formed new bark over the old wounds, and, as a rule, are remarkable for their bright clean

Pippin for home use, I should be sorry to recommend it for market work, as it is too uncertain. Though the trees may bloom most profusely, it seldom occurs that a heavy crop follows. My experience is that only a moderate crop can be reckoned upon, and though the fruit will realise a satisfactory price in the London market, it will not realise anything like the amount per acre that some of our large cooking varieties will make. W. G. C.

**The Apple blossom weevil.**—I thought it might interest you to know that the Apple blossom weevil is now depositing eggs in the small unopened buds in enormous quantities. I have carefully examined several orchards lately and found the major portion of the buds punctured and the weevils continuing the process. If this is general it will be a serious matter for fruit growers.—S. T. WRIGHT.

**Chaumontel Pear.**—On page 257 "Y. A. H." appears surprised that I had a good word for the flavour of the above variety. If the promise on our trees is realised this year, I shall have much pleasure in sending "Y. A. H." a dish for him to test, and I think he will acknowledge the good qualities of the fruit, unless we have a bad season for their ripening. I believe "Y. A. H." was at the Hereford fruit show last November, and if so

he probably noticed the splendid dish of Chaumontel staged by Mr. Ward, Steke Edith Gardens, in his first prize collection of Pears. That grower informed me they were from pyramid trees, and, unless I am mistaken, also stated that the flavour was always good. As Mr. Ward is a reader of THE GARDEN, perhaps he will kindly correct me if in error.—W. G. C.

**Protecting fruit blossoms.**—This will now need attention in most gardens, and as both Peach and Apricot trees are scarce of flower in the majority of places, extra trouble should be taken to protect what there is from the ravages of frost. Single fish netting is of little value as a frost-resister, and when double it is not effectual if sharp frost should occur immediately after rain. My experience is that frigi-domo or tiffany is the only safe material. If it is used of moderate thickness only and sufficiently porous to admit sun and light, it may be allowed to remain down in front of the trees during the day as well as the night, being kept from pressing against the blossoms by means of stout poles let into the ground and securely fixed at the top of the wall. Crops of Pears are sometimes lost from want of a little protection. In unsheltered situations espaliers are difficult to protect, but much may be done towards saving the bloom by fixing between the wires small boughs of Yew or Spruce. J. C.

### CROPS OF GRAPES.

At the present time growers will be considering how many bunches they can leave on their Vines with a certainty of their finishing up well. Some are too anxious to secure a heavy crop and leave so many bunches, that the Vine is strained to its utmost power to perfect the crop, and very often it is unable to accomplish such a feat, thus inflicting a great injury to the Vine. The varieties of Grapes are so different in their strength and productive powers, that what may be a fair average crop on one kind would be an absolute failure on another. Take White Frontignan as a case in point; if it were permitted to carry as heavy a crop as Foster's Seedling or Golden Queen will bear with ease, shanking would be practically certain to set in, and the berries that did not shank would never have the finish and delicious Frontignan flavour which makes this Grape so much appreciated in many places. To get White Frontignan really first-class, I think a crop at the rate of half a pound to each foot run of rod is a fair weight with extra strong Vines and a soil well adapted to the variety. More might, perhaps, be obtained, but even then I believe it best to keep near the weight mentioned, thus avoiding any risks and ensuring a similar crop annually. Lady Downe's Seedling is another Grape that may easily be overdone in cropping, and I have committed errors with it on two occasions; in each instance the wood made was remarkably strong, and great care had to be exercised in tying down the sub-laterals. To check this gross habit, I allowed an extra heavy crop to remain, almost every lateral having a fair-sized bunch, and some bunches of large size. Apparently no harm was done, as the crop in each case coloured up well, but later on the bunches did not keep so well in the Grape room, and the following spring the Vines started irregularly and much weaker, with smaller bunches. Supposing the Vines of Lady Downe's Seedling are moderately vigorous and in good health, 1 lb. of fruit per foot of rod is sufficient, and those growers who expect to have and try to secure the same weight from it as from Black Alicante or Gros Colman are courting failure. With respect to the two last-named varieties, my experience is that no other Grapes will produce such a heavy crop year

after year. With the Vines in good health and planted in a suitable border with the roots thoroughly under the cultivator's control, strict attention to feeding and other important details being also given, Black Alicante and Gros Colman will carry from 2 lbs. to 3 lbs. of Grapes for each foot of rod. For market work they pay better than any other sorts, and of late years I have sold all out by Christmas. Muscat Hamburgh, Madresfield Court, Mrs. Pince and Lady Hutt should not be expected to bear more than 1 lb. per foot of rod; in fact, Muscat Hamburgh will be finer in berry, finish and flavour if that weight is a little less, as it is always somewhat uncertain in colouring up perfectly, and if the weight is at all beyond the powers of the Vines, a foxy hue is sure to be the result. The evil effects of overcropping Mrs. Pince have been recently mentioned in THE GARDEN, and I need add no further remarks beyond stating that my experience agrees with that of the writer's. Muscat of Alexandria is undoubtedly the king of white Grapes when well grown, but to have it perfect in colour a very heavy crop should be avoided. I have had Vines of this variety in a house 15 feet wide that finished up a crop well with an average of over 40 lbs. per rod, but I found that the Grapes failed to keep well in the Grape room after February, while other Grapes of the same sort from Vines not carrying more than half the weight were plump and sound until the end of May. Some of the most lovely coloured and largest berried Muscats that I ever saw were staged in Edinburgh some years ago, and the grower informed me that he attributed his splendid examples to always allowing the laterals to be fruitless between each bunch, or say a bunch on every fourth lateral on each side of the rod. No doubt many would consider the crop a light one, but when such a system combined with high cultural skill can produce Grapes of such remarkable merit, it is worth while to give the plan a fair trial. Mrs. Pearson was recently figured in THE GARDEN, and a well-deserved recommendation given the variety. In addition to the remarks then made it may be stated that, with the exception of Foster's Seedling, I believe no other white variety will produce so heavy a crop of good Grapes year after year as Mrs. Pearson. If the Vines are in robust health, 2 lbs. per foot of rod will not distress them or interfere with future crops provided the feeding is sufficient for requirements. For a long time I considered Golden Queen the most prolific of all white Grapes, but experience has convinced me that it is bad policy to permit this variety to bear more than 1½ lbs. per foot of rod. In some seasons a heavier crop will come out all that could be desired, but in others it will be disastrous. Last year I had one Vine of Golden Queen that was of extra strength, and I left on a big crop of bunches, at least 2 lbs. per foot; everything went satisfactorily until the last swelling, and then the berries became marked with dark lines, or, as usually termed, "muddy," and when ripe the flavour was very inferior. The good old Black Hamburgh is often overcropped, and it is astonishing that it stands so much ill-use so well.

Amateurs who only have a few Vines are especially prone to leave so many bunches on, that it is a marvel the Vines do not utterly break down under the strain. When the Vines are very strong, 1½ lbs. or 2 lbs. per foot can be carried with safety, but with weaker Vines half that weight will be ample. No one can state exactly how many bunches or weight a Vine may carry unless he is well acquainted with the soil, feeding, and skill brought to bear upon their cultivation, as one man may be able to

obtain as much as 4 lbs. per foot of rod of really good Grapes by carefully allowing no wasted energy and a judicious system of high manuring. Another man who has equally as good vinerics and every facility for the growing of Grapes will frequently fail to get 1 lb. of well-finished Grapes per foot of rod through not taking careful observation of the Vines' requirements, and also going over the sub-laterals at regular intervals, shortening back such growths wholesale instead of removing all surplus shoots with the finger and thumb immediately they are large enough to pinch out. I am also a strong advocate for the early removal of all bunches not likely to remain to ripen on the Vines. For many years I have cut off these surplus bunches before the blooming period with gratifying results, and have never had cause to regret doing so. W. G. C.

#### PEACH LEAVES DISEASED.

I ENCLOSE some Peach leaves, and hope you will be able to tell me what is the matter with them and whether the disease is likely to spread to the other trees.—J. McC.

\* \* \* The leaves sent are not diseased—at least, such is my opinion. In all probability only some portion of the branches or, say, one side of the tree is showing signs of debility, and if those branches do not die outright this season they will not long survive. It is the stems that are affected, and it is owing to a deficiency of sap that the leaves are changing to a sickly glaucous hue, little or no further progress being made. When large branches fail in the manner indicated they may as well be cut out at once, as the fruit on them will inevitably drop off. The decay of bark and stem partakes somewhat of the form of canker, and according as sap communication is cut off from the roots the branches will fail. Gumming is sometimes responsible for these occurrences, and strong sunshine pouring direct on the stems is thought by some to injure the bark, slow decay resulting; while faulty stoeks are also blamed for some failures. Whether this cankerous affection is the result of a bad bruise of stem or sunburn I am unable to decide, and can only advise cutting away all dead portions of bark, neatly rounding off where sound, and then coating with clay and manure to facilitate the formation of fresh bark. In any case it is advisable to commence the preparation of a young tree to take the place of that failing, taking care when moving the former in the next or following autumn to give it the benefit of quite fresh loamy soil. Should the other trees give signs of becoming sickly, then there is most probably something seriously wrong at the roots, nothing short of wholly lifting and replanting in fresh fibrous loam to which bone-meal and "burn-bake" have been added, using the latter most freely. This lifting of trees should be done in the autumn after the wood is well matured and before the leaves have fallen. Peach and Nectarine trees pay well for this treatment whether they are in a sickly state or not. Some of the most successful growers give their trees the benefit of a fresh supply of loam every autumn. It should, perhaps, be added that it is a good plan to screen exposed stems from bright sunshine, enclosing them in wooden boxes made to fit them, perhaps answering best.—W. I.

**Strawberry Royal Sovereign.**—I am pleased to see the note at p. 262 by "S. W. F." on the above, as it so fully agrees with my own opinion as to its merits for forcing and good cropping qualities. As regards earliness, I am not able to place it before Noble or Vicomtesse H. de Thury, as I did not place the plants indoors at the same time. From close observation I think it may be termed a first early. The large firm fruits require time to ripen if flavour is the first consideration. I find the flavour excellent, brisk and refreshing. It is

a splendid cropper; the flower trusses are thrown well above the leaves, setting freely. When this variety has been grown specially for early forcing, the runners obtained from maiden plants, it will doubtless prove one of the best early forciers we have. I have not yet been able to give it the same favourable treatment as some of the older kinds, but intend to do so in future.—W.

**Feeding Gooseberry trees.**—Few fruit trees receive less manure than the Gooseberry, so many other things require it, but even with a short supply these trees well repay a little attention. I prefer the spring months to any other time for mulching, as there will then be finer fruits and less trouble with red spider. The Gooseberry suffers badly from the pest named, but a good rouch keeps the roots moist. A good dressing of decayed manure—cow manure—is excellent for light soils. We collect the strawy litter which has done service in covering early crops and place neatly over the surface under the trees, and having plenty of liquid manure, this latter is poured freely over the straw, which prevents it running away and retains the moisture. This is done twice a month.—S. B. M.

**Fig trees.**—It is only now that the full extent of the frost and its bad effects can be seen on Fig trees. In most instances they are in a sorry plight. Even those trees that were protected by Fir branches have all their young wood quite killed; other trees not protected not only have all the young, but much of the old wood killed or seriously injured. As all this dead or dying wood absorbs sap to some degree from the tree, it will be advisable to cut away all such portions at the earliest possible date if not already done, thereby preventing any waste of energy and also inducing the back buds to start into growth more rapidly. Of course no fruit can reasonably be expected this year, but a good foundation for next season's crop can be laid by ensuring an early growth that will be well ripened by the time the foliage falls.—W. G. C.

#### VINES NOT BREAKING.

Will you kindly tell me the cause of my Vines not breaking? I took charge of them last summer. They were covered with mealy bug, and the Grapes were so dirty that they could not be made use of. The shoots were very weak. The house is used as a plant house as well as a vinery and the border is outside. I scraped them rather hard in winter, and scrubbed them with soft soap and Gishurst compound. There are eight Vines in the house; four have started and four have not.—W. J. WRIGHT.

\* \* \* If all the Vines had failed to start I should have been disposed to blame the severe scraping and dressing with soft soap and Gishurst compound for the collapse. Many hard scraped rods, however, annually receive a rather strong dressing without apparently being greatly damaged thereby, and we must look in some other direction for the destructive cause. Vines in a house that has to be used during the winter for plant growing do not, as a rule, get sufficient rest, a weakly, irregular break resulting in most cases. Keeping the house warm enough to exclude sharp frosts for any great length of time is almost certain to excite the Vines into growth earlier than desirable, and directly sap movement commences that portion of the rods outside is very liable to injury from frosts. They ought, therefore, to be very carefully protected, not merely during the winter, but till all danger from severe spring frosts is past. It may be some of the stems were not so well protected as the others, but of this W. J. Wright ought to be the best judge, and I can only write conjecturally. Haybands put on a year or more ago, or not very closely bound together when used last autumn, would not prove sufficient protection against such an extra severe frost as we experienced in the winter, but surrounding them with dry sawdust enclosed by boxes would have saved them. If the outside of the stems is split or burst, frost is to blame, and nothing else. No amount of scrub-

bing or dressing during the winter will wholly rid the Vines of mealy bug, but if what few of the latter that escape are hunted for and destroyed during the early part of the growing season, the cleansing will be complete.—W. I.

#### BEST STOCKS FOR VINES.

I AM obliged to "W. G. C." and Mr. J. Crawford for their answers to my query. No doubt I and, perhaps, many others will greatly profit from their kindly advice. As I have not got Black Alicante I shall be obliged to graft Muscat Hamburg upon the Muscat of Alexandria. Some three or four years ago I planted two new vineries. In the early house I planted Black Hamburg, Foster's Seedling, and Madresfield Court. When I first saw a whole house devoted to Madresfield Court I instantly fell in love with it. It was in the year 1888 at The Dell Gardens of Baron Schroeder where I saw it for the first time.

In the second house I planted Black Hamburg, Madresfield Court, and a few rods of Gros Colman. The early house is just fit for the first thinning; the second house will be in flower in about two weeks. Now allow me to tell you what have been the results with Madresfield Court for the last two years. In the early house the berries were subject to cracking and never got their proper colour. In the second house quite the reverse happened, the bunches as well as the berries being large, with no cracking and of good colour. Now what is the matter with them, why do they behave so differently? Mr. Barron tells us in his excellent treatise upon the Vine that Madresfield Court is an early Grape, best suited for early work and requires less heat than Black Hamburg. The Vines are generally not subjected to a great amount of heat with me, especially from the colouring period onwards.

With Gros Colman I never have good results—even in September the colour is quite foxy. Would it be advisable to plant Gros Colman in the early house, or is there any hope that it will do well in the same house if grafted upon the Muscat of Alexandria?

When I got home some five years ago from my rambling abroad I at once adopted the English system of pruning—I mean the spur system, or, better still, the short spur system. Up to that time everywhere in this country was followed the long rod system, and here and there one happened to see a few rods pruned on the spur system, but upon the long one. I confess as I pruned my Vines to the first spurs I did it hesitatingly, saying to myself, in England there is another climate, probably more favourable to this short pruning than with us in our cold country. But, nevertheless, I did it—at least on the permanent Vines, but on the temporary ones I did not venture doing this.

Last year I pruned my permanent Vines, which in the meantime had reached about two-thirds of the rafter, quite close. Just then an old gardener called upon me, looked over the pruned rods, and said in an admonitory voice, "If you want to get bunches, you must prune to two or three eyes, but never so close as that." R. KATZER.

*Pawlowsk, near St. Petersburg.*

**Apple Pine-apple Russet.**—I believe this is a very old Herefordshire Apple, as a few old trees are scattered about the country, but it appears to be dying out. I have a few bush trees, from which I annually have a few excellent fruit, but after trying this variety in almost every form of tree I have been unable to secure a good crop. This year the prospects are superb, every bush tree being covered with bold fruit buds, and if the season is favourable an excellent crop should be the result. Locally the variety is named the Old Pomeroy, and is highly appreciated by those acquainted with it for its earliness and rich flavour. In its season (end of August and early in September) no Apple is equal to it in this part

for flavour. If it would only be more productive, few Apples would be more sought after. Old standard trees make little growth and in the summer the foliage assumes a yellow tinge, as if in bad health; but bush trees worked on the free stock make plenty of strong shoots, with large, dark-coloured foliage. It would be interesting to know if this variety is more prolific in other places or on a different soil to our light, hot one.—W. G. C.

**Tasmanian Apples.**—These are arriving in very good condition this year, and a portion of the cargo of the *ss. Curaco*, which brought 12,000 cases, was sold by auction, realising prices which are said to be remunerative to the colonial fruit growers, whilst they are decidedly satisfactory to the London consumers. The excellent quality of the Tasmanian Ribston, Cox's Orange, New York, Sturmer, and King Pippins, and of the Scarlet Pearmain, Alfriston, and Prince Alfred Apples is widely recognised. They fetched from 9s. to 16s. per case, coming into competition with the last of the Nova Scotian and Canadian Apples, which are selling at 16s. to 20s. Were it not for the introduction of Apples from the Antipodes, we should have difficulty in replenishing the dessert dishes this year, as there are no English-grown Apples to be had, last season having proved disastrous. The Cape fruit, which was obtainable for about a month, has almost ceased to arrive, and no other source of supply will be available until July, when Lisbon consignments are expected. Until then Tasmanian Apples will practically have sole command of the market.

#### THE MELON.

EARLY Melons have not come on so rapidly this year as they usually do. I generally sow the seed about the first week in January and the young seedlings come on slowly during that month and February; but owing to the continuation of the cold weather the plants made weak growth. There is some difference of opinion as to the best treatment of the plants until they are ready to plant out. The young seedlings should be planted singly into 3-inch pots as soon as the seed leaves have grown to their full size, and the plants should go into the soil almost as deep as the leaves. Place the plants on inverted flower-pots up near to the glass roof where they can obtain plenty of light, which promotes a healthy growth and compact habit. Re-pot them into 5-inch or 6-inch pots as soon as they are ready, and they may remain in these until they are ready to plant out. The best method of cultivating early Melons is to train the growths to a trellis fixed about 10 inches from the roof-glass. The best soil is good yellow loam to which has been added a fourth part of decayed manure. Tread or press this in firmly, and let it be in the heated house a week or so before planting out the Melon plants; by that time the bed of soil will be sufficiently heated, and the plants should be put out about 3 feet apart. The leading growth is trained up to the trellis, and this ought not to be stopped before it has grown to within 18 inches or so of the top. Melons do not require, nor do they thrive so well in rich open composts as Cucumbers, but the soil ought to be moderately rich and the bed made firm. The plants do not require a very large space for the roots to run into. A bed about 2 feet wide and 18 inches deep will be quite sufficient with ample drainage. The base of the trellis need not be very much above the bed of soil. Four to six fruits are a sufficient number to grow upon a plant, and the female blossoms should all be open about one time, say within twenty-four or thirty-six hours of each other. If two or three fruits get a few days' start there is little chance for those that come later. I remember once having to plant a house of Melons where the base of the trellis was over 3 feet above the bed, but I happened to have some 2-foot glazed tiles about 12 inches in diameter, and I filled these with good compost

and placed them on the bed of soil. The Melon plants were planted in the tiles, the roots ran down into the bed, and I had a most satisfactory crop of fruit. The only trouble there is with Melon plants is their tendency to damp off at the neck and the liability of the plants to the attacks of red spider, which is a most troublesome pest, but it can be kept down by daily syringings.

J. DOUGLAS.

**Strawberries and the frost.**—I was as surprised as sorry to read Mr. Wythes's note on the unsatisfactory condition of Strawberries in the open quarters at Syon. Here in South Notts the plants, though slightly injured, do not appear to be at all crippled. There is on all varieties in our garden plenty of old foliage in a green state, while new crowns and leaves are abundant. I am glad to find the Gunton Park seedlings have stood the winter as well as any. This fact strengthens my opinion that these fine Strawberries are destined to become popular market varieties. Some of the newly-raised sorts are all very well in warm, sheltered gardens, but in open fields and ordinary market gardens they are useless. Coupled with a good constitution, the Gunton seedlings, Lord Suffield, Gunton Park and Empress of India, possess the very finest flavour. We are getting some unwelcome frosts now, and should these continue a short time longer the flowers on the earliest kinds will be injured, if not destroyed. What makes one more fearful is the remembrance of the terrible frost of the middle of May last year. In regard to mulching Strawberries in the autumn, I have great faith in the practice, provided short littery material is used. This may be saturated with urine, the strength of which will be washed down to the roots during winter and greatly benefit the crop the following year. Using very rotten manure is, I consider, a mistake, especially on soils which are not of the warmest character, as the manure becomes wet and then frozen, this ruining many of the surface roots, which, of course, are the best.—J. CRAWFORD.

**Peach buds dropping.**—At page 193 I set down what I believed to be the reason of Peach trees dropping their buds. I believe that in many instances bud-dropping is the effect of the causes I have given. That there may be other reasons, I am quite ready to admit. "Peach Grower" and "Wiltshire Gardener" (page 257) give evidence in their writing of being skilful gardeners and have full knowledge of the cultural requirements of their trees. They tell us the young growths have been well thinned out, the leaves kept clean and free from aphid or red spider, and the borders well watered. Borders may be too well watered if Chrysanthemum plants are set upon them for two or three months at mid-winter. It may be well to seek for the evil in the constitution of the variety, and I recollect a case in point. Some twenty-five years ago I was an enthusiast in orchard house culture, especially the culture of Peaches and Nectarines. I must have grown some fifty or sixty varieties and proved them. Amongst others I had a yellow-fleshed variety named Exquisite which bore six fruits the third year from the bud, and these six were good enough to win a first prize against fifty-three competitors early in September. Some of my gardening friends planted it out in their Peach houses, and I do not know any of them who did not regret doing so, and for one reason only: the blossoms did not set well, and the fruit when it was obtained, though large, was not first rate as regards flavour from the planted-out trees. I must say that in the orchard house I had little or no trouble with buds dropping. I found Early Grosse Mignonne to be a very free setter, as "Peach Grower" has done, and the true variety is an excellent Peach. Hale's Early is an excellent early Peach with which I had no trouble, nor had I any trouble with the American variety Alexander or with the very early varieties raised by Mr. Rivers, of which I thought Early Rivers was the best.—J. DOUGLAS.

## TREES AND SHRUBS.

## CARPENTERIA CALIFORNICA.

KINDLY allow just a word of explanation. I imagined from what Mr. Miles wrote to you that, under some special process of Mr. Smith's, *Carpenteria californica* was doing quite well in his hands, and I wanted to know what it was, but I now find from a letter he has been so good as to send me that Mr. Smith's advice was relating to something else. From what Mr. Miles says, I should fancy that his shrub and mine are in very much the same plight, and that there was little more to be done for them than what they have had at our hands. But what a difference does this reveal between the state of things at this time and what it was a year ago! The *Carpenteria californica* was apparently happy enough and on the straight road to present us in early summer with a most glorious picture. Now it is certainly alive—though I was afraid to say as much as that of it at first—but there is no chance of its blossoming this season.

Of course, what Canon Ellacombe says about serviceable precautions in winter is quite correct, and many are the hints he has given me about shrubs, &c., during the last twenty-five years, but on one point in his letter I cannot quite rest in the conclusion to which he has come. It is a very easy thing to say that such and such a plant is short-lived, and therefore its disappearance cannot be helped, there is no cause for regretfulness; but how can my old friend be quite so certain that he is right? In very many cases of this sort I should dissent from his dictum altogether, and if a post-mortem examination were to be held after the decease of some favourite flower or shrub, I should often want, if I were a juror, to bring in a verdict of culpable planticide rather than that of death from merely natural causes. I will give an instance in point. *Fremontia californica* has the reputation of being very short-lived, and I have been myself told as much. For all I know to the contrary the sad experience which I had with it in the year 1893 may have been cited in proof of it. But that is far from being the way in which I should look at the matter. I reproached myself at the time, and I reproach myself still, for letting the most glorious specimen in the whole country slip through my hands as it did. It died here from sunstroke, and if I had been aware of its danger, as I might, and as I think I ought to have been at the time, it would be alive now. So also I am persuaded it is with very many other things which are reputedly short-lived—they are mismanaged, and then we say to ourselves when the worst has come to the worst, it is all very natural. Because of this I prefer to ask questions right and left, and I feel sure that good must result from it. If my garden wall had been painted white at the back of *Fremontia californica*, and if a few handfuls of straw had been tied round the main trunk of the tree, it would have been perfectly happy in all the heat and glare. The omission to do this I put at my own door, and it cost me the finest thing in my garden. The death must be assigned to preventable causes.

Since writing to you the other day I have noticed two more survivals, which are of very great interest to me. *Crinodendron Hookeri* (which I raised from a cutting given to me at Bilton) has apparently pulled through this hard winter, though of course it is cut up a good deal, and *Rosa gigantea* (which was given to me at Kew as a very questionable thing in point of hardiness) is in exactly the same case. The judgment of one of the best gardeners in

the Isle of Wight—Mr. Smith, of Appley—coincides with my own on this head, and if I can make these two things do well—and they cannot have worse terrors to go through in the future than they have already met with in the past—it will go far to compensate me for some great disappointments.

But it is perfectly certain that the Isle of Wight is hit now as it has scarcely ever been before in our time. It will take two years for my rock garden to be again at the point at which it stood last autumn, and only a few days ago a young man who seemed to know what he was talking about told me that he had been wandering a good deal over different counties of England during the last few weeks, and he never saw anywhere such marks of the desolating frost as he found here. The reason for it I take to be this. We have been accustomed to think that we never could have any great cold in these parts, and therefore when it did come we were vulnerable in all sorts of ways, and we were quite at its mercy. But some things have gained when many others have suffered. It is a true saying that what is meat to one person may be poison for another. Never, so far as I can remember, has *Magnolia conspicua* looked more promising than it does now, and instead of being nipped and injured, as is so frequently the case, it will in a few days' time be a perfect picture of the most unsullied white. I have a *Magnolia* of this sort which must be about 12 feet high, I should say, and near it stands another of still greater size. I refer to *Magnolia grandiflora*, of which I am very fond. But what a difference do their cases present! *Magnolia grandiflora* is literally browned from head to foot; it is just as though the hand of "chill October" were on it still, and the ground is littered with the falling leaves. Very soon, I suppose, the branches, which are usually covered with thick glossy green leaves, will be bare and naked under a summer sun. The one of these two *Magnolias* is a sort of representative at this moment of radiant happiness. Being deciduous, it gave no point of attack to the desolating wind and the biting frost. The other is a kind of symbol of disappointment and sorrow; it went on merrily at first and took things unconcernedly as they came, but it has had to pay a penalty of a grievous sort. The winter of 1894-5 has given the worst possible turn to the one of these two trees and the very best turn to the other. We must in a garden take the bad with the good and be thankful that things are with us as they are.

HENRY EWEANK.

*St. John's, Ryde, Isle of Wight.*

P.S.—It occurs to me to mention that *Shortia galacifolia* has been very indifferent to the ordeal we have had during the last winter. Four or five large plants here have been beautifully in blossom in the open air for a month past.

**Bambusa aurea.**—I never saw this grow so luxuriantly as at Send Hulm, Woking. Owing to the late hard winter, the leaves look the reverse of green, of course, but what struck me was the great length to which the sucker-like canes had reached. I measured some 14 feet in height and as thick as an ordinary walking-stick. Being interested in the cultivation of *Chrysanthemums*, I envied such excellent neat sticks, which furnish the best of supports for these rather tall-growing plants. The Bamboos are planted near a magnificent lake.—S.

**Historical trees at Walmer.**—Among the trees in the grounds of Walmer Castle there is an *Acacia* which is pointed out as having been planted by Queen Elizabeth. From its size and

appearance it looks as if it might have been raised from a seed borne by the tree that good Queen Bess is said to have planted, but it can hardly be the original. There is also a Yew which Lord Clive is credited with planting; also a very handsome Tulip tree and a splendid group of Limes which tradition has associated with Pitt and Fox. The Duke of Wellington planted here a cutting from the Willow by the grave of Napoleon at St. Helena, which lived till shortly after Earl Granville became Lord Warden. The tree in question stood in the garden, and there is a Willow in the moat that is said to have been a cutting from it. Lord Granville planted in 1887 a cutting from a Willow planted at Tully Allan by the Comte de Flahault, who had accompanied the Emperor in most of his campaigns and attempted to go with his fallen master in his exile. He was afterwards ambassador to Vienna and London. The clumps of trees in the meadow, as well as those on the beach in front of the castle grounds, were planted by Earl Granville.—W. T. B.

**Buddleia globosa.**—At Send Hulm, near Woking, a very large specimen of this showy flowering shrub has been entirely killed by the frost. This had evidently braved many severe winters, and its inability to live through the late protracted hard weather is one more proof that even in very sheltered positions plants and trees have suffered to an unusual extent. In the same neighbourhood I observed a well-balanced symmetrical *Cedrus Deodara*, about 20 feet high, had the northern side browned as if it had been burnt by fire. As the sun gains power we shall no doubt find many instances like this of damage done by frost.—S.

## GARDEN FLORA.

## PLATE 1011.

## GAZANIAS.

(WITH A COLOURED PLATE OF *G. BRACTEATA*.\*)

THE plate this week represents a very beautiful species of *Gazania* which was sent to Kew by Mr. Gumbleton, of Queenstown, Ireland, in the spring of last year for identification. Mr. Gumbleton received it under the name of *G. pygmaea*, but it seemed so different from that and the allied species in its size and involucre, that I considered it distinct, and described it as a new species under the name of *G. bracteata*, because the outer row of involucre bracts sprang from near the base of the tube of that organ instead of near the top in the form of teeth, as is usual in this genus, for until now the involucre has been considered to afford good specific characters. But later in the season Mr. Gumbleton sent two other forms raised from the same packet of seed which, whilst differing from the form previously sent in their involucre and colour of their flowers, were evidently conspecific with it, and seemed to show that the involucre is not altogether to be relied upon for distinguishing the species, so far as the length and position of the bracts composing it are concerned. This caused me to more closely re-examine the whole of the Kew material, with the result that, firstly, I find the genus *Gazania* is one of the most perplexing a botanist has to deal with, more especially when he has not the opportunity of seeing the plants growing in abundance in a wild state, so that their range of variation may be understood; secondly, that the leaves and involucre, within certain limits, are very variable in what is certainly the same species; thirdly, that the size and facies of the plant, as is the case with several other South African composite, are more or less altered by

\* Drawn for THE GARDEN in Mr. Gumbleton's garden at Belgrove, Queenstown, Co. Cork, by M. L. S. E. Lithographed and printed by Guillaume Severeys.

cultivation. And I am now of opinion that the plant I have described under the name of *G. bracteata*, despite its very much larger size as grown by Mr. Gumbleton and at Kew, is really the same as *G. pygmaea*, under which name it was sent from Natal by Mr. Adlam to Mr. Gumbleton, and *G. canescens* is also the same plant. On the Continent it is known as *G. nivea*, but that plant is described as having crenate-pinnatisect leaves clothed with white wool on both sides, and is no doubt from the western part of South Africa, whilst this one has the leaves usually entire, glabrous above, and is from the eastern part of South Africa, in a district that collectors had not reached when *G. nivea* was described. Therefore, for the plant represented in the accompanying plate I propose to substitute the name *G. pygmaea* for that of *G. bracteata*, under which I previously described it, the following being a brief account drawn up from cultivated specimens of the plant and the two varieties that I have seen.

*G. PYGMAEA* (Sonder, in "Linnaea," v. 23, p. 69). Synonyms: *G. canescens* (Harvey, in Harvey and Sonder "Flora Capensis," iii., p. 478); *G. bracteata* (N. E. Brown, in *Gardeners' Chronicle*, 1894, v. 15, p. 620); *G. nivea* (Leichtlin, in *Höner Illustrirte Garten Zeitung*, 1894, p. 81, f. 21, not of Lessing).—A beautiful half-hardy, herbaceous perennial of tufted habit, with linear leaves that are smooth or somewhat scabrous and bright green above, snowy white beneath, with more or less revolute margins; occasionally a pinnate leaf is also produced. In a wild state the leaves are only 1 inch to 4 inches long, but under cultivation they attain a length of 6 inches to 9 inches. The peduncles are about as long as the leaves and glabrous. The flower-heads are 2 inches to 2½ inches in diameter, the ray-florets being white, without a spot at their base, and striped with purple beneath; the disc is yellow; the involucre is glabrous and scarcely hollowed at the base, its outer bracts sometimes arising near the base and very long, as in the accompanying plate, sometimes arising above the middle and much shorter, or reduced to teeth about twice as long as broad.

*G. PYGMAEA* VAR. *MACULATA* (N. E. Br.).—Leaves smooth above, peduncle and involucre glabrous, the latter hollowed at the base. The flower-heads are about 2 inches in diameter, the ray-florets 1½ lines to 2 lines broad, pale creamy white, with a blackish spot at the base and a dull purple stripe down the back.

*G. PYGMAEA* VAR. *SUPERBA* (N. E. Br.).—Leaves scabrous above, especially towards the margins. Peduncles slightly scabrous. The flower-heads are as large and the involucre hollowed at the base as in the preceding variety, but the ray-florets are 2 lines to 4 lines broad and pure white, without a spot at their base, with a bluish stripe down the back. This form is much the prettiest of the three; the greater breadth of the rays gives a more compact appearance to the flower, and the white being of great purity makes it a very charming and effective plant for rockwork and other decorative purposes. Natives of the Transvaal, Natal, Orange Free State, &c.

Besides the above species, only about four others of this pretty genus of Compositæ have been introduced into cultivation, although several of them are well worth growing, as a glance at the subjoined enumeration of what appear to me to be the best and most distinct species will readily show.

#### I.—ANNUAL SPECIES.

*G. BURCHELLI* (De C., Harvey and Sonder, "Flora Capensis," v. iii., p. 479).—One of the most distinct species of the genus, sometimes very compact, at others with elongate branches. Leaves linear, with revolute margins, entire, or with one to three lobes on each side, not white beneath, very hispid, and the margins beset with white bristles, with which also the apex and lobes

are tipped. Heads 1½ inches to 1½ inches in diameter, yellow, with a purple spot at the base of the rays; the peduncle and involucre more or less hispid or setose, and the tube of the involucre with numerous reflexed, spine-pointed bracts. A native of Namaqualand, Orange Free State and Bechuanaland.

*G. LICHTENSTEINI* (Less., Harvey and Sonder, "Flora Capensis," v. iii., p. 479).—A small and well-marked plant. The stem divides into several prostrate branches, bearing oblanceolate or spatulate toothed leaves, which are quite flat, or with very narrowly revolute margins, and at first covered on both sides with a cottony tomentum, the upper side becoming glabrous. The teeth and apex are bristle-pointed, heads 1½ inches to 2 inches in diameter, yellow, with a dark brown spot at the base of the rays, which are purple beneath. The glabrous tube of the involucre is about twice as long as broad, with short, acute teeth, and the base hollowed out with a sharp edge. Native of Namaqualand.

*G. TENTIFOLIA* (Less., Harvey and Sonder, "Flora Capensis," v. iii., p. 479).—A neat species, in habit like *G. Lichtensteini*, but the leaves are pinnate, with two to six linear lobes on each side and revolute margins, green and scabrous above, white beneath. The heads are very freely produced, but only about three-quarters of an inch in diameter, yellow, with a blackish spot at the base of the rays. The involucre has three to four series of narrow, hard-pointed bracts on the tube and between them is neatly marked with white tomentose lines. The base is broadly obconical, with a projecting rim. Native of Namaqualand.

#### II.—PERENNIAL SPECIES.

A.—Leaves mostly or all pinnatisect, or a few entire.

*G. PAVONIA* (R. Br., *Botanical Register*, v. i., t. 35).—An old inhabitant of our gardens, having been introduced into cultivation about the year 1804 by Mr. G. Hibbert. It is one of the finest species of the genus and much resembles *G. rigens*, but the leaves are mostly pinnatisect, green and smooth above, white beneath. Heads 3 inches to 3½ inches in diameter, rich orange-yellow, the base of the rays marked by a large blackish-brown spot, in which is a blacker spot more or less surrounded by white, the peduncle and involucre covered with soft, bristle-like hairs. A native of the southwestern part of Cape Colony. Synonyms: *Gorteria pavonia*, Andrews, "Botanical Repository," t. 523; *Gorteria heterophylla*, Willdenow, "Hortus Berolinensis," t. 98.

*G. PINNATA* (Less., Harvey and Sonder, "Flora Capensis," v. iii., p. 476).—A fine showy species; leaves mostly pinnatisect, with linear or oblong-lanceolate lobes; rough, with short bristly hairs above, white beneath; peduncle roughly hairy, heads 3 inches or more in diameter, yellow, with a black spot at the base of the rays; involucre roughly hairy, hollowed at the base, the teeth shorter or longer than the tube, acute, or drawn out to a long fine point. Native of the southwestern parts of Cape Colony.

*G. JURINEFOLIA* (De C., Harvey and Sonder, "Flora Capensis," v. iii., p. 474).—A very dwarf and distinct species. Leaves all pinnatisect, about an inch long, smooth above, white beneath, the lobes bristle-pointed and with bristles on the petioles. Peduncles as long as or shorter than the leaves, glabrous. Heads about an inch in diameter, the rays white without a basal spot, striped with purple beneath, the disc yellow; the involucre is glabrous, not hollowed at the base, and has short, ovate, acute, mucronate teeth. A native of the Orange Free State and the district of Colesberg, in Cape Colony.

B.—Leaves about half pinnatisect, half entire.

*G. SUBULATA* (R. Br., Harvey and Sonder, "Flora Capensis," p. 473).—A very fine showy species. The leaves are glabrous on both sides, not white beneath; some are pinnatisect with two to three linear lobes on each side, some are narrow linear and entire. Peduncles more or less setose. Heads 2½ inches to 3 inches in diameter,

yellow, with a blackish purple spot at the base of the rays, which are purple beneath; involucre glabrous, hollowed at the base, the teeth three-quarters of an inch long, subulate, the outer ones ciliate. Cape Colony.

C.—Leaves mostly or all entire.

*G. LONGISCAPA* (De C., Harvey and Sonder, "Flora Capensis," v. iii., p. 474; *Gardeners' Chronicle*, 1883, v. xx., p. 77).—This, which is one of the better kinds, appears to have been introduced many years ago, as there is a cultivated specimen in the Kew Herbarium that was placed there prior to 1867, but it was probably soon lost to cultivation and re-introduced about 1882 or 1883, when it was described by me at the place above quoted. Leaves all entire or with some pinnatisect leaves mingled with them, white beneath, with more or less revolute and sometimes ciliate margins. Peduncle glabrous. Heads 1½ inches to 3 inches in diameter, yellow, with or without a black spot at the base of the rays; involucre glabrous, hollowed at the base, the teeth as long or longer than the tube, subulate, and very finely pointed, the outer ones ciliate. Native of the eastern parts of Cape Colony and Natal.

*G. UNIFLORA* (Sims, *Botanical Magazine*, t. 2270; Loddiges' *Botanical Cabinet*, t. 795).—This species appears to have been introduced into cultivation about 1820, and although not so showy as some of the kinds, is still worthy of the gardener's attention. It is more lax in habit than most species, the branches being somewhat elongated and decumbent. Leaves lanceolate or lanceolate-spatulate, with occasionally a pinnately divided one among them, bright green above, white beneath. Heads 1½ inches to 2 inches in diameter, bright yellow without a spot at the base of the rays, which are coppery purple beneath. The involucre varies from nearly glabrous to white-tomentose, and has short acute teeth.

*G. UNIFLORA* VAR. *LEUCOLENA* (Harvey, "Flora Capensis," v. iii., p. 472).—Like the type, but both sides of the leaves and the involucre are densely white-tomentose. Natives of sandy places near the coast of Cape Colony.

*G. RIGENS* (Sims, Harvey and Sonder, "Flora Capensis," v. iii., p. 473).—This is the oldest and best known species in the genus, and one of the most beautiful. It was cultivated by Miller prior to 1755, and has never ceased to be a favourite with gardeners. The leaves are mostly entire and linear-lanceolate, with now and then a pinnatisect leaf among them, bright green above, white beneath. Peduncles glabrous. Heads 2½ inches to 3 inches in diameter, bright orange-yellow, the rays with a blackish spot at their base, having a white mark in the centre of it; involucre glabrous, with short acute teeth. Synonym, *G. splendens*, Moore, *Floral Magazine*, v. i., pl. 19; *Illustration Horticole*, 1860, v. vii., pl. 235.

*G. RIGENS* VAR. *PURPUREA* (N. E. Brown).—Like the type, but the flower-heads have a blackish-purple disc and rich purple-red-coloured rays, with a black spot at their base. This variety must certainly be a very attractive form, but I have never seen a living specimen and doubt if it is in cultivation, although it is a plant that is well worth introducing. Curiously enough, however, on turning to Miller's "Figures of Plants," v. i., t. 49, I find that it must be this very variety which he figures, although on page 33 of that work, wherein the plant is for the first time described, he states that "the rays are of a gold colour within, but of a pale yellow on the outside. At the base of the rays there is a beautiful circle of black chequered with white, and the disc within the circle is of the same colour as the rays." In the plate, however, both ray and disc are represented of a dark red colour and not at all golden. Possibly the artist depicted one variety, whilst Miller described the common well-known form. Another curious point in the history of *G. rigens* is that the native locality is at present unknown so far as I am aware, for although it has been cultivated for 140 years, no wild specimen of it was contained in the Kew Herbarium until this year, when flowers of the purple variety were received, but

are not localised; nor had Harvey when writing the "Flora Capensis" seen any but cultivated specimens. I have a suspicion, however, that the plant grows either in the neighbourhood of Saladanah Bay or in the district of Tulbagh.

*G. ARMERIOIDES* (De C., Harvey and Sonder, "Flora Capensis," v. iii., 478).—A dwarf compact species, very distinct in character. Leaves linear with very revolute margins, sometimes rolled back to the midrib, rough with short, stiff, ascending hairs, and terminated by a bulbous-based white bristle; the peduncle and involucre densely covered with soft spreading hairs. Heads 1 inch to 2 inches in diameter, the rays white without a spot at their base, purple beneath, the disc yellow. The teeth of the involucre are very variable, being sometimes no longer than the tube, sometimes two to two and a half times as long, and obtuse with a mucronate point or very acute or subulate pointed. A native of the eastern districts of Cape Colony and Natal, at 3000 feet to 8000 feet elevation.

*G. CESPITOSA* (Bolus in "Journal of the Linnean Society," v. xviii., p. 393).—This is perhaps the most remarkable of all the species, although the flowers are not so large as in several of them. Very densely tufted or thick procumbent woody stems. The leaves are very numerous, about an inch long, very rigid, linear, spinulose-ciliate, glabrous. Peduncles short, glabrous; heads  $1\frac{1}{2}$  inches to  $1\frac{1}{2}$  inches in diameter, yellow, with no spot on the rays; involucre glabrous, with a cylindrical tube hollowed at the base and striped with dark purple on a green ground; the teeth are shorter than or as long as the tube, rigid and hard pointed, the outer ones ciliate at the base. This grows on the Sneeuwbergen Mountains, in the district of Graaf Reinet, Cape Colony.

N. E. BROWN.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**PEACHES AND NECTARINES—EARLY HOUSE.**—Early Alexander and other early American kinds will now be swelling freely and should be encouraged by mulching the surface soil and feeding with liquid manures. The earliest varieties are this season later than usual, owing to the dull, cold weather that prevailed when the trees were in bloom. No time should be lost now in going over the trees. Fruits shaded by shoots or leaves should be freely exposed to the sun so as to get good colour and flavour. The early American Peaches require much sun to get flavour, and as many fruits are on the undersides of the trees, they may be freely exposed by removing useless shoots and leaves. Feeding must cease when swelling ceases, and there must be less moisture overhead. A warm dry temperature must be maintained, but I do not advise keeping the house dry, as by damping floors and walls and giving air freely during the day a sweet growing atmosphere is maintained. Previous to ripening it is well to thoroughly moisten the border, as the flavour of the ripe fruit will be affected if watered at that period. The leading shoots, or those required for extension, should be given the best position on the wall or trellis, as these will be better matured if allowed ample space. In regulating the shoots at this date many may be removed if they are at all thick. These early varieties are more difficult to manage than older kinds, and to prevent bud-dropping the best means should be now taken to ripen the wood, this being the best preventive and a safe one. The shoots for next season's bearing that are growing too freely may have the points pinched out, as they are not required too gross, 15 inches to 18 inches being ample as regards length. The lateral growths should be stopped to one leaf as they form, not allowing them to attain any size. It is an easy matter to remove any badly shaped or small fruits at this stage if at all crowded, as there is no fear of dropping now, and

in the case of weakly trees it is well to crop lightly. These latter should be encouraged by supplies of a quick-acting fertiliser well washed into the soil with tepid water afterwards. Strong growing trees may fruit freely, this to some extent checking gross wood. The temperatures for houses in which the fruit is stoning may be raised, a night temperature of 65° to 70° and 10° higher by day, allowing the thermometer to run up freely at closing time, and with warmth in the pipes there should be ample ventilation during bright sunshine.

**SUCCESSION HOUSES.**—The trees in these houses will have been making good progress of late and the fruit should now be stoning. Our best standard Peaches and Nectarines, such as Royal George, Early Grosse Mignonne, and Lord Napier Nectarines fruit freely, but there is no gain by leaving too many fruits, and by early thinning of badly placed fruits, those which are prominent have a better opportunity to swell and attain a large size. Crowded wood and small fruits are not profitable, and are difficult to manage. Shoots with fruit at the base may be made good use of if stopped at a few leaves above the fruit; they act as feeders during the swelling, and are readily removed when the fruits are gathered. The trees do not yet present the neat appearance of the early forced trees with their new growths tied in, as it is well to allow the young growths free play for a few weeks till the wood is firmer and there will be less danger of breakage. The shoots, too, may be better placed to expose the fruits as much as possible. The old system of leaving a large quantity of fruit till the final swelling is not advisable, impoverishing the trees and reducing the size of the fruits left to mature. With ample roots, food and moisture, and freedom from sudden fluctuations of heat or cold, there is little fear of dropping after the fruits have attained a fair size. It is well to leave as many fruits as possible on the upper part of the trellis, but they should be equally distributed all over the trees. Syringing will now be an important point of culture and must be regularly attended to, as green fly, red spider and other pests will increase rapidly, and should black fly make its appearance it is well to remove it quickly by frequently fumigating, dusting the affected parts with tobacco powder, leaving the latter on the trees for a day and then syringing freely. Ample supplies of food are needed when the fruits are swelling, and by change of food much finer fruit is obtained. By giving liquid manure and a good fertiliser alternately there is a great gain, as too much liquid from animals closes up the soil. Temperatures may be slightly raised, but it is well to maintain a low night temperature with all stone fruits till the last swelling or ripening period: 60° to 65° will be sufficient at night, the last named in warm weather with a rise of 10° by day, thoroughly wetting all portions of the trees and house when closing, using water of the same temperature as the house.

**LATE HOUSE.**—Disbudding and thinning will be the chief work in late houses, and as the trees frequently get badly infested with green and black fly, means must be taken to get rid of the pests as soon as the fruits are set by repeated fumigations, not in strong doses, but several nights in succession, giving the trees a thorough syringing afterwards to remove any fly the smoke may not have reached. Many young cultivators use the syringe too lightly, missing the parts of the trees most difficult to reach. These are the parts soonest infested by fly, being most exposed. Late houses should get full air by day and a liberal circulation at night, the top ventilators being left open, but have sufficient warmth in the hot-water pipes to prevent the thermometer falling below 45°. Syringe sufficiently early to get the foliage dry by sunset, and by early syringing the trees grow more freely. After the fruits are set the trees should receive liberal supplies of moisture, and as growth increases food may be given freely. The remarks as to thinning for early houses apply here with more force; as so many fruits set, it is well to thin early. Cases or unheated houses should not be retarded in any way during the

flowering period, but the same attention given as advised above.

**THE ORCHARD HOUSE.**—This house if not hard forced, but used for a variety of fruits, will now require much attention. The trees being in pots with increased top growth will require more moisture, food also, and those who do not re-pot annually will require to feed early and give their trees rich surface dressings as soon as the fruit has set. The Peach and Nectarine will claim first attention, disbudding and thinning being important details. With pot trees I do not advise severe thinning, as in the case of large planted-out trees, as often the fruits drop more when swelling should there be a check in any way. Severe stopping will be necessary to equalise the growth, only leaving sufficient new wood to furnish the trees for next season and for extension, stopping the shoots almost close to the fruit or the bearing wood. In watering these trees give liberal supplies in fine weather, as should the balls once get over-dry, the fruits drop badly and others fail to swell. In syringing see that all parts of the trees are thoroughly moistened. Trees introduced late will need more air and less moisture, but avoid cold draughts, frequently examining the trees, removing useless wood and fruit, and feeding as growth increases.

**CHERRIES.**—These now swelling fast should get liberal treatment, airing freely on bright sunny days, and giving liquid manure or surface dressings of a good fertiliser. Cherries being surface rooters need early mulching with rich food, which feeds and saves the watering. Thinning in the case of fruits well advanced may now take place, as in many houses the fruits have nearly finished stoning and it will now be safe to thin them. Cherries drop up to the time they commence to colour, so that early thinning is not advisable. Keep a sharp look out for black fly, one of the most troublesome pests these trees have to contend with, as when the fruits ripen it is difficult to get rid of it by syringing, so that it is well to keep free of the pest in the earlier stages. Trees with the fruit nearly ripe should have the shoots laid in, these if at all dirty being given a coating of tobacco powder or dipped in tobacco solution. Trees well supplied with water and food are less subject to attacks of insects, and robust trees either in pots or borders take large quantities of water when bearing heavy crops.

G. WYTHES.

### KITCHEN GARDEN.

**PEAS—PRINCIPAL SOWING.**—This must now be made in order that the crop may arrive at maturity before the midweek season sets in, as when growth is late this scourge sometimes clears it off in a very short time. Selection is of the greatest importance in this sowing in order to avoid a glut at one time. For those who are short of ground, I recommend mixing the seed of various sorts and sowing it in the same rows to prolong the supply. Allow plenty of space between each row where practicable, and on heavy, wet soils take out shallow trenches, filling the same with any fairly rich, light soil, applying artificial manure later on rather than digging in animal manure previous to sowing the seed. Stourbridge Marrow, Veitch's Perfection, and the deservedly popular Criterion are excellent, the same sorts being again sown in about three weeks' time—Ne Plus Ultra, Walker's Perpetual Bearer, and British Queen being best sown the first week in June for late autumn supply.

**LATE CELERY.**—Where room can be spared for several, or even one row of late Celery it will be found invaluable to help out other vegetables, especially should the winter be severe and the majority of the Broccoli perish. For flavouring purposes also it may be used, and thus the better blanched samples spared for ordinary use. An ordinary cold frame with a sunny aspect will answer capitally for sowing the seed in, keeping it close till growth is visible, afterwards fully exposing it in fine weather to harden and induce stocky plants. Leicester Red is about the best

Celery to stand a wet winter and general exposure, Standard-bearer and Wright's Grove Red also being very good. As this batch will make the most of its growth at a later date, much manure is not advisable, as it is apt to induce hollow growth and consequent rotting. Mushroom manure dug into the trenches now will be in good condition for the balls of roots by the time the young plants are fit for transplanting. When the seedlings are fit for pricking out frames will not be necessary; any well-sheltered corners where the sun gains admission and where rough boards can be arranged round the plants and mats thrown over at night will answer well. Celeriac may still be sown, the variety called Early Paris being useful as a second dish in winter. The seed should be sown in a little warmth and the young plants pricked out in due time, being finally lifted with good balls and planted in rows from 18 inches to 2 feet apart and 18 inches from root to root, planting in drills in preference to trenches and on the level on heavy soils.

DANDELION.—This is much esteemed in many places where winter salads are in request, the fereed tops forming a pleasant change from Endive and Lettuce. Being perfectly hardy, a portion may be left in the ground all the winter and allowed to come on naturally in spring. If needed in a blanched state small batches should be lifted at intervals and placed in the Mushroom house. That left in the ground can be readily blanched in spring by covering the crowns with Seakale or large flower-pots and covering with leaves.

SALSIFY AND SCORZONERA.—Rows of these may now be sown where they are to grow, the plants being duly thinned out to the required distance as soon as large enough. This crop pays for rich ground, as on soil at all hungry or shallow the roots become tough and of poor quality. The foliage being very liable to the attacks of fly must be watched as soon as through the ground and sprinkled occasionally as recommended for Turnips.

SOWING GLOBE ARTICHOKE.—I am aware that, as a rule, a great percentage of Artichokes raised from seed are worthless, yet after severe winters offsets from established clumps are so scarce, that sowing seed is compulsory. This should if possible have the advantage of a warm, sunny corner in order to hasten on the plants, so that it may be seen during the first season which are worth retaining. Some gardeners sow the seed in pots or pans and pot on the seedlings, growing them in comfortable quarters and afterwards hardening off, finally planting out with the balls intact. Where there is no scarcity of ground a good batch should be raised and planted out for trial 18 inches apart.

PLANTING ASPARAGUS.—In most gardens this may now be done. It should be borne in mind that however much trouble and expense the preparation of the new beds may have cost, failure and disappointment must ensue unless due care is bestowed on the seedlings at planting time. I believe careless planting has much to answer for in the many failures in growing this vegetable. The rootlets are of such a delicate character, that exposure to cutting winds for a few minutes, or even to hot sun, may destroy them. When the roots have to be sent from a nursery, arrangements should be made for packing them in damp Moss or some such material. When home-grown roots are employed, the matter of transplanting is made easier. A calm and, if possible, dull day should be chosen for the job, and, presuming that the beds were prepared at the time advised, the soil will now be nice and firm and need not be trodden. Some still prefer the old-fashioned 4-foot beds, but unless the soil is retentive and cold it is not necessary to raise them above the ordinary level. I get capital results from planting single rows, allowing a distance of 2 feet from plant to plant and a 2½-foot alley between. For the first year or two this space can be utilised for Lettuces. Lift only a few plants at a time, sprinkling the roots and planting carefully with a small handfork. If the compost is not of the best description, work

in a little fine loam and leaf-mould amongst and around the roots. Sink the crowns just beneath the surface, and if the young growths have pushed, draw a little soil over them to protect from frost until somewhat hardened. Nothing more will be needed except keeping down weeds until growth is a foot or 18 inches high, when small sticks should be placed to each plant and the shoots secured thereto, as high winds are very liable to loosen them at the base and sometimes snap them off. This precaution is not necessary the second year. In regard to varieties, Conover's Colossal and Reading Giant are capital for the main cuttings, while the late Argenteuil forms a good succession. On hot soils, if the summer should be dry, a slight mulch of leaf-mould will be beneficial.

SMALL SEEDS.—Secondary sowings of various Kales may now be made, plenty of that absolutely frost-proof variety Asparagus being allowed for, the dwarfier forms also of the Scotch or curly being better for latest supplies than the taller, as they are more easily protected by snow. The old Cottager's Kale is still one of the most useful, as are also Read's Hearting and a variety commonly known as Ragged Jack. Choose a somewhat shady position, as the seedlings will come on quite fast enough, and allow plenty of room between the rows at this date, this being more needful than in the earlier sowings. Couve Tronchuda, or Portugal Cabbage, is a most delicious vegetable, coming in most useful after the latest autumn batches of ordinary Cabbages, and finding great favour in the dining room. It may be sown now and treated in all ways similarly to other green crops.

LATE BROCCOLI.—In midland and northern localities seed may now be sown of the majority of spring Broccoli. In the more favoured counties a fortnight later will be a better date for a few sorts. Amongst reliable kinds may be named Veitch's Spring White, Penzance, Cattell's Eclipse, and the old Leamington. For continuing the supply until the handlight Cauliflowers are ready I find none to equal Veitch's Model, Late Queen, and Methven's June; these, and especially Model, are extremely hardy and of good quality, and being dwarf in growth stand severe winters far better than do the more leggy varieties. Sow thinly and give plenty of room between the rows, finally planting out if possible on plots from which Spinach, spring Cabbage, or other early crops have been cleared, and that without any further preparation of the ground, a solid bottom favouring a stiff hardy growth. If room can be spared for a few rows of the early white and purple Cape they will be found most serviceable at a time when Broccoli is not over-plentiful. These may be planted between rows of Potatoes, a course which should always be avoided with sorts that have to stand through the winter.

PICKLING CABBAGE.—These in common with ordinary spring Cabbages succumbed in many places to the severity of the winter. Where seed was sown in good time in January as advised, the plants will now be sufficiently advanced and hardened to admit of planting in their permanent places. Give extra rich ground, as there will be none too much time for making large solid heads. It is a good plan whenever sowing small seeds to include a small quantity of summer Cabbages, as these fresh and young are always acceptable and can be planted out on any odd plot or corner not large enough for main batches of winter greens. Cocoa-nut is one of the most useful Cabbages for summer sowing, turning in quickly and being of excellent flavour.

VEGETABLE MARROWS.—Seed may now be sown in small pots to produce plants for planting out under handlights or other protective agents in June. Sow a couple of seeds in each pot and select the best plant, moving to a cool greenhouse temperature as soon as growth appears through the surface in order to secure a hardy constitution. Moore's Cream, Long White, Pen-y-byd, and the Custard varieties are all suitable for this sowing, giving good returns when well cared for. If plants sown earlier and intended to be planted out in early Potato frames are likely to become pot-bound before the frames are cleared, give another

liberal shift, using good rich soil, and assist growth by occasional doses of liquid manure, as if once Marrows become stunted and yellow they are practically useless. J. CRAWFORD.

## FLOWER GARDEN.

### THE ROCK GARDEN.

#### V.

APRIL 4.—ROCK PLANTS IN BLOOM.—This week has added two more choice Saxifrages to the plants now in bloom. Saxifraga Boydi is in flower not only at Exeter, but also at Newton Abbot and at Torquay. This little gem very much resembles *S. Burseriana*, but its flowers are of a clear beautiful sulphur-yellow. It is still scarce and a very slow grower. In the various rock gardens in the towns mentioned it occupies the same position, viz., slightly sloping ground fully exposed to the sun, and planted in a narrow crevice containing very stony, calcareous soil, a position which seems to suit it. The other little gem now blooming is *Saxifraga retusa*. Its appearance just now is altogether unique, and it would make a good companion to the first named variety (*S. Boydi*). The leaves are very small and compact, reminding one more of those of *Androsace pyrenaica* than of a Saxifrage. The flowers, nestling on this cushion of dark green foliage, are bright rose with a dark purplish red centre, and stamens of the same colour. These Rockfoils deserve one of the choicest corners in the select part of the rock garden. *Morisia hypogea* was flowering here in January, when six weeks of unusually severe frost set in and the plants were partly covered with snow. It is now, however, continuing to bloom just as if nothing had happened. Gentians are showing as yet only buds here in Exeter, but in a rock garden at Newton *Gentiana verna* is already in full bloom. At Torquay *Rhododendron Vaseyi* is also in flower. This American species would grow too large among the alpine, but in the background of a rock garden it well deserves a place. The flowers, of a bright pink colour, appear before the leaves. In the same rock garden I noticed large groups of *Primula capitata* in full bloom, presenting a charming sight with their large heads of lilac blossoms. Here at Exeter various other *Primulas* have opened out of doors, including *P. nivalis* with pure white flowers, the dark purple *P. intermedia* and the lilac *P. denticulata*. In the rock garden the best place for these varieties would seem to be a partly shaded stony ground. *Shortia galacifolia* is blooming now in various places in Devonshire, looking perhaps at its best in a shady nook of the rock garden at Abbotsbury. *Draba aizoides* is following closely upon *Draba Aizoon*, which commenced to flower last week. At a first glance both resemble each other, but *D. aizoides* is of a deeper golden yellow colour and its leaves are shorter than those of *D. Aizoon*; both seem to do best in a narrow crevice fully exposed to the sun. *Iberis stylosa* flowered in January and is now again in bloom, but its foliage has been slightly injured by the frost, which is not to be wondered at when such hardy plants as *Iberis semperflorens*, *I. sempervirens*, &c., have been cut to the ground by the severe weather.

A very effective plant now blooming is *Corydalis solida*, which is equally well adapted for the larger rocks or for the rocky border. The rosy purple flowers are very showy, and the glaucous, much-divided foliage is equally effective. This is, however, a plant which should

not be planted too close to the smaller gems, which it might injure by its robust growth, although it does not spread so rapidly as the better-known yellow Fumitory, which is not in bloom as yet.

The same position, *i.e.*, a part of the rock garden away from the smallest alpinics, should be given to *Orobis vernus* and *Omphalodes verna*, which are now flowering; the former has Vetch-like lilac flowers of a pleasing shade, those of the latter being brilliant blue. *Omphalodes verna* is an excellent plant for naturalising in a wild garden, where large patches are most effective.

Of Anemones, only two kinds are as yet in bloom here, *viz.*, *Anemone vernalis* and *A. Pulsatilla*, the former with flesh-coloured and the latter with dark purple flowers, and both of peculiar shaggy appearance. *A. vernalis* I find does best in a half-shady position, while *A. Pulsatilla* seems to prefer a moist spot fully exposed.

*Saxifraga Huetti* has also opened its yellow flowers; this is not a plant for the select part of the rock garden, as it spreads too quickly, but where in the rougher and more shady part a quickly spreading, bright green carpet is desirable, nothing could be better.

Of *Androsaces*, only *A. carnea* is out in bloom so far; the bright pink flowers springing from a mossy cushion of greenery are very attractive. It strongly objects to calcareous soil and does best in a half-shady position on almost level or only slightly sloping ground.

(To be continued.)

### THE ALPINE PINK.

(*DIANTHUS ALPINUS*.)

THIS pretty little Pink is still comparatively rare in gardens, as it is not one of those things that once planted in the rock garden practically

*Dianthus alpinus*. Engraved for THE GARDEN from a photograph sent by Mr. E. H. Lushington, Cobham, Surrey.

takes care of itself afterwards, although in suitable positions it does not give much trouble, but spreads into dense tufts of deep green growth seldom rising more than 3 inches in height. The proper place for it in the rock garden is one sunny and exposed, but where it can have abundance of moisture so that it should be as near the ground level as possible. Although moisture-loving, there must be no

stagnant water in the soil, a good depth of light material—well-decayed leaf soil is as good as anything—from which all excess of water can rapidly drain away being the best. The more exposed the plants are the healthier will they be and the greater the number of flowers. This species is easily distinguished from other alpine Pinks by its dark shining green leaves. The flowers, which appear in June and July, are borne singly on a slender erect stem, but so profusely from flourishing plants as to quite hide the foliage. They are each about 1 inch in diameter, deep rosy purple spotted with crimson. There is a distinct dark zone of colour around the eye and the edges of the petals are fringed. A coloured plate of this plant was given in THE GARDEN of August 30, 1884.

**Pentstemon cuttings.**—At page 158 of the last half year's issue of THE GARDEN will be found some remarks on the treatment of cuttings taken from the *Pentstemon* late in the year. It has been gratifying to me to find even in this unusually severe winter not a single cutting injured, although there was no other covering but a bell-glass. Instead of using a wooden frame with a glass top to cover them as I had intended, I used several bell-glasses of various sizes, from a 9-inch to one only 4 inches in diameter, under which last I found could be placed three cuttings. These cuttings will not put forth any roots until the sun's rays have deeply penetrated the soil; but they remained covered from the end of October last to the 12th of the present month (April), when the bell-glasses were removed for a few hours in the middle of the day. Should the weather become very hot during the next few weeks the soil will be watered and the glasses replaced during the hottest portion of the day. It is of importance not to lift the plants until some of them indicate growth at their points, which will probably not be before the end of May; the best rooted will then be removed to the quarters where they are to remain, and any that have not yet struck, if only just beginning to do so, will be replaced, watered, and have their glasses set over them for a few days to stimulate their growth. The first laterals taken from the *Pentstemon* in early autumn make better plants than those taken at a later date and soon root, but they will need the protection of a frame or greenhouse during the winter, and are never so strong or so good for that purpose as plants which have been raised during the preceding winter in the manner herein recommended.—B. S.

**Daphne rupestris.**—Referring to Mr. Wood's note on the above in THE GARDEN of March 16 (p. 187), I believe that about twenty years ago Messrs. Baekhouse received a considerable consignment of this species, collected in the neighbourhood of Bondone, near Storo, in the Tyrol. It was thought to be a great improvement (as a rockwork plant) on *D. cneorum*, in being much more compact in habit and having larger flowers of a finer and softer colour (rosy pink) and equally fragrant. I do not remember from what authority Messrs. B. derived the name of *D. rupestris*, under which they grew it. I think they were the first to send it out in England.—W. M.

**Scilla sibirica on the Grass.**—We have but few blue early-flowering plants that are suitable for planting on the Grass, which makes this *Scilla* doubly valuable. It is very pretty growing in groups on borders and beds, but far more so when grown in big masses on the Grass. I have this *Scilla* growing in this way under some Lime trees. The Grass being somewhat thin, it thrives splendidly. I planted the bulbs some three years ago, and they improve every year. Some planted two years ago at the foot of a large Ash and under a Chestnut tree are also doing well. I make a hole and drop in two or more bulbs, according to their size. It is a pity the *Scillas* do not flower a week or two earlier, so as to be in bloom with the Snowdrops. Can any reader tell

me whether *Chionodoxas* will thrive in this way? Just now they are lovely in patches in beds and in the rock garden.—J. CROOK.

### ANEMONE APENNINA.

THIS lovely spring flower carpets the ground in the woods of Italy just as the Wood Anemone does in Britain. It grows freely in almost all

*Anemone apennina*. Engraved for THE GARDEN from a photograph sent by Miss A. Worsley, Rotherly Lodge, Clifton.

soils and is to be had cheaply in large quantity, so that that there is no reason why it should not be planted extensively. Only a poor idea of its beauty can be gathered by planting it in little tufts about garden beds and borders, but by putting it in the grass we see it under conditions such as it grows in its native land and which add materially to its effect. There are many spots about most gardens where this Anemone could be planted and left to take care of itself, and after a few years a series of pretty pictures growing yearly in extent and beauty will be the result. We have tried it in many ways and it has never failed. It does not increase quite so fast in stiff loam, but in light, free soils it runs rapidly, and will make a carpet as thick as the Anemone in the woods. In thin plantations where the sun can reach it beautiful effects might be made, and in grass it is specially charming, coming into flower in April, its clear blue stars borne just above the points of the fresh green growing grass. A coloured plate of this Anemone was given in THE GARDEN of August 18, 1894.

### FLOWER GARDEN NOTES.

THE week ending April 13 has been an exceptionally favourable one for outdoor work, and all flower garden operations requiring attention were accordingly rushed along rapidly. The Dutch hoe has been run through all autumn-planted beds of Pinks, Carnations, Violas and the like; also all herbaceous borders, taking particular care in the latter instance not to injure any plants just on the move, and which as yet are barely perceptible. The ground being in capital working order, many autumn-struck herbaceous plants have also been consigned to permanent quarters, either to fill up beds or to be sparingly planted where the remaining portion of the ground is to be presently filled with other things. I found on looking through the clumps of outdoor *Chrysanthemums* of the Desgrange and outdoor early-flowering pompon sections that they are either killed outright, or that the old stools are so erippled as not to be worth saving. The latter have therefore been cleared away, to be replaced with a batch of December-struck plants. The chief drawback to the Desgrange family is their

very formal appearance. They make, however, in flower a bank of colour and are useful for large beds associated with Starworts of somewhat similar height, or, better still, with a broad edging of Pentstemons. All Chrysanthemums being gross feeders, the ground destined for the reception of these summer-flowering varieties should be well prepared. If there are a few more than are required for outdoor work they may be potted on and will be very acceptable for the conservatory or to associate with such things as Fuchsias, zonal and other Pelargoniums, Begonias, &c., in outdoor groups of pot plants.

**BOXING OFF.**—Many boxes were set at liberty with the planting out of herbaceous subjects, and advantage has been taken of this to shift a quantity of bedding stuff from the cutting pots. I like to have rather small boxes, 18 inches by 12 inches by 3 inches being quite large enough to handle with ease, and as plants are never required to remain long in them a lot of soil is not necessary. In making them care should be taken to put the bottom strips fairly close together, not more than an eighth of an inch apart. This may seem somewhat superfluous advice, but it is really an important matter, especially for present boxing operations. A considerable distance between the strips means an enormous amount of drainage in proportion to the size of the box, the water running through them as through a sieve, and a consequent inability to keep the plants sufficiently moist later in the season, given a spell of hot, dry weather and boxes full of roots. It is not advisable to box thickly; sufficient room should be allowed for the free development of the plants. Seedlings and spring-struck cuttings of Petunias and Verbenas if intended for special purposes are the first to receive attention, as, being fairly hardy, they will be among the first to be planted out. The dwarf Ageratum will also require early attention, it being one of the bedding plants requiring a longer season of growth. The culture of Lobelias had in many places been abandoned in favour of the more enduring Ageratum above-named and the different shades of purple Violas, but the advent of Barnard's Perpetual Lobelia has given them a new lease of life, this being not only a great, but, as its name implies, a continuous bloomer. Dwarf plants of tender habit that are likely to be required for carpet bedding where this style of gardening is still practised may also be boxed. I have before referred to the usefulness of home-made frames for hardening off where permanent pits and frames are somewhat scarce, and just notice them again at the present time because a man handy with saw and hammer can, with the aid of a few inch boards and some pieces of quartering, soon put them together. The quartering may be driven into the ground at intervals of about 6 feet and sawn off square at the top at a height of 4 feet for the back and about 15 inches or 18 inches for the front of the frames. The boards can then be fastened on either side the quartering, enclosing a space of about 3 inches, which may be packed with dry Fern, Heather or straw. If no glass lights are available, skeleton lights, stout poles or open hurdles can be laid across the frames, and if a good night covering is put on, no spring frost we are likely to have will find its way to the plants. Any of the hardier type of bedding plants that are still in fruit houses where a rather high, moist temperature is maintained should be promptly removed from thence, or leggy, weakly growth is encouraged that will get badly nipped with the first exposure to cold winds. Before passing from the bedding plants it may be noted that with all things that come under this category the aim should be to secure nice sturdy, stocky plants, because one good plant is worth three or four bad ones. Also avoid undue crowding either in pot, pan or box, and as these get full of roots, water thoroughly when required, giving not a surface sprinkling, but a thorough soaking that will penetrate right through the soil.

**CARNATIONS.**—I am sorry to hear that the personal experience noted in a recent number as to

the border Carnations having come safely through the winter is not a common one, many growers having to chronicle heavy losses. Under these circumstances, unless the loss can be supplied by the purchase of other stock (a rather expensive business if there are many gaps), the best substitutes for the current season will be found in the Grenadin and Margarita types. If these were sown as advised in February the seedlings will by this time be sturdy little plants and may be pricked out into a frame in prepared soil, pushed along as rapidly as possible, and planted out as soon as they are ready. If any Pinks remain in the cutting frame they can be used to fill one or two beds. Some of the newer kinds, as Mrs. Walsh, Her Majesty, Ernest Ladhams and Ascot, throw large and beautiful flowers, which are excellent for cutting. As, however, they are over earlier in the season than Carnations, it is hardly advisable to allow them to monopolise the whole of the beds. They may be planted in large clumps and the remaining portion of the bed presently filled with, for instance, large plants of Fuchsias or Ivy-leaved Pelargoniums, for which the foliage of the Pinks will furnish an admirable carpet.

**FRANCOA RAMOSA.**—Where this is grown rather largely alike for the conservatory and to be presently associated with other things in outdoor groups of pot plants it is advisable in the case of old plants with many breaks to stake them out a bit, so as to secure a good breadth of flower-spikes; also, if a succession is required, to place a portion of the stock on the sunniest shelf of the greenhouse, an earlier development of flower-spike being thereby secured. It should, however, be remembered that while the plants will do with plenty of sun they must have a dry atmosphere and a fair share of air. Anything approaching a moist, stuffy atmosphere is decidedly injurious. The flower-spike will start under such conditions, but the chances are that instead of developing its flowers it will come to a premature ending.

Claremont.

## ROSE GARDEN.

### ROSES IN INDIA.

WRITING from Baroda on March 29, Mr. Goldring says as to Roses:—

You ask about Tea Roses here. The general practice here is to bud very low, so that practically you have own-root bushes. Sometimes layering is done, but it is not a general practice to strike from cuttings. Ever since I have been here (the middle of October) we have had Roses in abundance, and just now as the hot season is setting in the bushes are laden with bloom, particularly Maréchal Niel, Lamarque, Celine Forestier, and such kinds. Hybrid Perpetuals, especially the dark kinds, do not do well, too hot and dry for them, but the Polyantha Roses are in their element. I can cut bushels of Roses every morning from one garden alone, the bushes being enormous, some 10 feet to 12 feet through. They grow thus because it does not do to prune out here, for they never lose their leaves; consequently you see the natural habit of Rose growth, which left alone is most graceful in most of the Teas and Noisettes, flinging out long arching shoots laden with bloom. I wish you could see the glorious colour effects we are getting now from the great tropical trees like Bombax malabaricum 50 feet to 70 feet high, covered with brilliant red flowers like single Camellias; also the Butea frondosa, vivid orange-scarlet pea flowers in dense masses, and the Poinciana regia, which when you see it for the first time in a mass takes away the power of speech. Such effects as these should be aimed at in English gardens, and, taking the hint from Nature's grouping, I am planting groups of 100 or more of the biggest trees, which in a few years will be a glorious sight. The present time is the beginning of the

hot season, and corresponds with our spring at home, when the trees that lose their leaves annually drop them and re-clothe themselves in a week, and in most cases throw out blossom at the same time, though the ground is parched and dry to a considerable depth.

I wish I could bring you photos of some of the splendid colour effects we get from climbing plants: some climb to the top of the biggest trees and then fall over with a dense curtain smothered with bloom. That lovely Thunbergia you figured recently behaves like this. It is quite impossible to realise what those glorious stove climbers here are from what they are under pot culture.

**A new Rose.**—Mr. Jackson Dawson, of the Arnold Arboretum, has produced from a cross between Rosa rugosa and R. Wichuriana a Rose which trails flat on the ground, with very thorny wood like rugosa, and with rugosa foliage in form and colour, with all the gloss of Wichuriana and flowers 3 inches across, of a fine light red. It is sure to be very useful in many situations. This is, I think, the first time it has been described. I consider it the most interesting Rose raised in this country for some time.—F. L. TEMPLE.

**Rose Her Majesty.**—This grand exhibition Rose has two faults, namely, the blooms are too large and they are extremely few as a rule. But to avoid these failings at Broad Oaks, Byfleet, Mr. Carpenter has a plan which I had not previously seen adopted in the case of this variety. It is well known to produce a few (generally a very few) shoots of extra length during the season. Now if these shoots be pruned in the ordinary way the results are those complained of above. The practice then is to peg the growths down nearly their whole length, only just removing the unripened points. Mr. Carpenter assured me that it is not at all uncommon to obtain a couple of dozen magnificent flowers from one plant by adopting this simple plan. It seems to me a way that might well be followed this season if the pruning has not already been done.—H. S.

### NOTES ON ROSES.

It is some years since our Roses were so backward as at present. Last year on April 17 my neighbour was able to cut a respectable bunch of Rôve d'Or, Gloire de Dijon, and Reine Marie Henriette from a sheltered wall. In 1893 my notes show that he cut the same on the 20th of the same month. This year growth is not more than 3 inches to 4 inches in length upon the same plants. These plants are on a south-west aspect, and consequently protected from the keen north-east wind prevailing as I write. I think this by far the best position for early Roses; they miss the keen winds and also escape too bright and early sunshine upon frosty mornings such as we have lately been experiencing. The great contrast between this season and last is most remarkable, and we are not likely to have growth forward enough to be injured by May frosts as was the case both in 1893 and 1894. It is sad to note the havoc caused by frost here in the south, yet I understand that once more Messrs. Cocker's Aberdeen Roses have escaped much injury, although they were unprotected. Surely they did not have the same severe frost as we registered, or else they were fortunately protected by a good layer of snow. It would be interesting to know if this was the case. Last year we had many insect enemies during April. Both maggot and fly were prevalent in 1893 and 1894 at this date, but I fail to see any at present. I do not believe a hard winter makes much difference to insect pests, and no doubt they will appear in due course. Referring once more to notes of previous years, I find that my maidens were staked and tied over once at this date in 1893 and 1894, but now it is difficult for an inexperienced hand to realise that there is a crop upon the ground after stocks have been cut back. In this district we never had worse prospects than at present. I am indeed sorry to hear that the Rev. Foster-Melliar's

standard and half-standard Teas have suffered even more than my own, where I fear not ten per cent. are alive, this including old and maiden plants and dormant budded stocks. Year by year we see the better plan is to grow our Roses as dwarfs in all possible cases. R.

#### SHORT NOTES.—ROSES.

**Rose Boieldieu** has not been good for several seasons now. We saw it at its best in 1887 and 1893, as it likes a hot and dry summer. It is not a Rose I can recommend for general culture, but it is sometimes so good that one hardly cares to discard it from a fair-sized collection.—R.

**Rose Dr. Grill** does not become known so widely as I should have thought. It is strange how here and there a good Rose seems to slip many growers. Nothing can be prettier or more useful in all ways than this, with its soft rose and beautiful coppery shading. *Dulce Bella* I have no doubt is synonymous with this.—R.

**Rose Mme. de Watteville under glass.**—This is coming good with me under glass this season. It is one of the very sweetest scented Roses grown and every bud is perfect when under cover. To get large flowers they need very severe thinning, but I prefer such sweet-scented and uniquely shaded blossoms in quantity.—R.

### STOVE AND GREENHOUSE.

#### HYMENOCALLIS SPECIOSA.

THE accompanying illustration will be at once recognised as an old occupant of our stoves, long known under the name of *Pancreatum speciosum*, but now included in the genus *Hymenocallis*, to which, indeed, all the other plants generally cultivated as *Pancreatiums*, with two exceptions, belong. These two are the hardy *Pancreatum maritimum* and *P. illyricum*, while the other *Pancreatiums* proper are of little value from an ornamental point of view. The reverse, however, holds good with regard to the varieties of *Hymenocallis*, every member of which is well worthy of cultivation.

*H. SPECIOSA*, herewith shown, was introduced into this country from the West Indies in 1759, so that it must be considered among the oldest of our stove plants. Unlike many bulbous plants, it is decidedly handsome at all seasons, for the rich green massive foliage is retained all the year round, and when crowned with its head of pure white, deliciously fragrant blossoms, it will commend itself to everyone. The plant grown under the specific name of fragrans appears to be the same as *H. speciosa*. Apart from its beauty as a specimen the flowers are also much appreciated when in a cut state.

*H. MACROSTEPHANA* is a very beautiful plant of doubtful origin, that has long been particularly well grown at Syon House. Of this a coloured plate was given in *THE GARDEN*, July 10, 1880. The leaves of this are longer and narrower than in the preceding, while the flowers are particularly striking by reason of the large funnel-shaped cup, which tends to convey the impression that it may be a hybrid between *H. speciosa* and *Ismene calathina*, as has been suggested by Mr. Baker. At all events it is a thoroughly good garden plant, and one whose flowering season is not limited to any particular period of the year.

The two named above are undoubtedly the best of this section, but the list is by no means exhausted, as in addition we have

*H. CARIBBEA*, with long, rather thin leaves and flowers, after the manner of, but less showy than those of *H. speciosa*.

*H. LITTORALIS*, too, is somewhat in the same way, but with longer flowers. The segments, however, are very narrow, but when the flowers are borne in large heads it is certainly ornamental. Some few years ago immense numbers of

this were imported by some of our nurserymen, and barrels full of bulbs could be purchased at the London auction sales, but it was by many quickly discarded on the ground that, as far as its ornamental qualities are concerned, it was greatly inferior to *H. speciosa* or *H. macrostephana*.

*H. HARRISIANA* is a pretty little species that will do well in the greenhouse or even in a frame. It is a native of Mexico and was introduced in 1846. Apart from the fact that it is more hardy, this species differs from the preceding in being deciduous.

*H. GUYANENSIS*, introduced about ten years ago, is remarkable from the long drooping segments of the flower being spirally twisted, thus rendering it very striking. Some individuals are, however, in this respect more pronounced than others.

The culture of these different species of *Hymenocallis* is not at all difficult, and some of them (*H. speciosa* especially) will stand for years in the same pot and flower well. Hence particular care should be taken when repotting to see that thorough drainage is ensured, and also to use a compost that will remain sweet a long time. Good turfy loam, lightened according to its consistency with peat or leaf mould, and sand will suit them well, while as the pots get

earlier stages is somewhat straggling. With age, however, it becomes more compact, and is so free-flowering, that the Kew plant is quite a mass of its magnificent blossoms. It is by some urged against this class of *Rhododendrons* that they do not remain so long in bloom as many other subjects, which is certainly true, yet they are so grand when in flower, and in the case of some of them so deliciously fragrant, that when at their best they are unapproachable by any other class of greenhouse shrubs. If planted out and allowed to assume the character of good sized bushes, these *Rhododendrons*, when at their best, are very fine.—H. P.

**Hæmanthus Kalbreyeri.**—This, which is by most authorities considered synonymous with *H. multiflorus*, it still frequently met with under the specific name of *Kalbreyeri*, and during the present season I have noted it several times in fine condition. A well-flowered example is when at its best a really charming object, the globular flower-head, composed of a vast number of blossoms, being most brilliantly coloured, and very unlike anything else that we have in our gardens. Unfortunately it does not, as a rule, thrive under cultivation, and the massive heads of blossoms are in most cases, at least, produced by freshly imported plants, as the majority quickly go back

*Hymenocallis speciosa grandiflora.* Engraved for *THE GARDEN* from a photograph sent by M. C. G. Van Tubergen, Jun., Haarlem.

full of roots liquid manure will be of service. One prominent feature in connection with these different species of *Hymenocallis* is that, unlike many other bulbs, they can with ordinary care be depended upon to do well and improve year after year. Of *Pancreatiums*, the pretty *P. illyricum*, a native of Southern Europe, was well shown in *THE GARDEN*, September 6, 1890. Both this and *P. maritimum* can during the winter be obtained at a cheap rate from bulb dealers. H. P.

**Rhododendron Forsterianum.**—This *Rhododendron*, now flowering most profusely in the temperate house at Kew, produces the grandest blooms of the many white-flowered hybrids that we have in our gardens. Most of the varieties here grown have been raised in this country, but *R. Forsterianum* was obtained by M. Otto Forster between the Moulmein *R. Veitchianum* and *R. Edgeworthii*. As might be expected from the crossing of two such grand flowered species, the blooms of this are very large, crisped at the edges, but not to the same extent as in the best forms of *R. Veitchianum*, while the yellow blotch on the upper portion of the interior of the flower is more in the way of *R. Edgeworthii*. The foliage is about intermediate between that of the two parents, while the habit of the plant during its

after their first season in this country. Under the specific name of *Kalbreyeri* this was figured in *THE GARDEN* November 15, 1879, about which time or a year or two later vast importations were disposed of in this country, so that it was for a little while very generally met with. A coloured plate of a second species—*H. coccineus*—was given in *THE GARDEN* July 15, 1893. This, which flowers in the autumn after the leaves have died off, is, unlike the last, very amenable to cultivation, and is a good greenhouse plant.—H. P.

#### OLD PLANTS OF CROTONS.

I HAVE a number of very large and old *Crotons* here. Could I moss the stems, as in the case of *Dracænas*, with any hope of succeeding in getting them to root, or could you suggest a better way?—A. C.

\*\*\* A deal would depend upon the condition of the plants. I have had to do with such plants and managed to overcome the difficulty. One variety dealt with was *C. variegatum*, which for several years had grown on and on until it was a straggling plant; the only remedy at a glance would have been pronounced to be that of severe pruning. To do this, as in the querist's case, would have been inadvisable, because within three months the plant in question was wanted for

exhibition. A stout iron hoop about 3 feet in diameter was fixed just above the rim of the pot. Tying was then commenced without adding any more sticks than those already inserted to hold the hoop. The shoots being long were easily twisted down, overlapped or intersected, and in due course, by the use of string only, a very shapely pyramidal specimen was built up, which when finished could scarcely be recognised as the former plant. Old Croton wood such as that in the plant in question will bear a lot of twisting about, almost like that of a Willow bough, the splitting of the joints being guarded against as a matter of course. If the plants that it is now desirable to deal with are such as the one just described, it will be a very good way out of the difficulty. A well-furnished pyramidal plant of a Croton presents in my opinion a far more attractive form than the dense bush plants so often seen. Possibly the plants in question may be very tall in proportion to their width; if so, the pyramidal form, but of less diameter at the base, can still be adopted. Again, if quite bare below, so that it would not be possible to furnish the bottom, a kind of standard or semi-standard form could be worked out. The long, narrow-leaved Crotons make beautiful standard plants. In one or other of these ways it would thus be possible to make good use of the best of these old plants unless they are quite beyond such manipulation as that suggested. Even if the best plants were so treated it would be a point gained; then the others could be partially pruned if not too bad, or severe pruning, if that be the case, could be practised, so as in due course to so overcome the difficulty of being "an eyesore." The pruning if done should be attended to at once, first letting the plants dry up at the roots so as to prevent in some measure the bleeding that must ensue.

It would be a doubtful process to try to restore the plants by binding Moss around the stems, but any likely looking shoots for cuttings could be so treated, first notching the stem below and afterwards gradually severing it. This is a very good mode of increase where there is no bottom-heat at command to ensure rapid root-action, as when the ordinary means of increase by cuttings is adopted. Although not stated in the letter of inquiry, it is just within the bounds of probability that the plants are overpotted. If this be the case, it might be stated that the old balls may be reduced with safety; such a treatment would greatly help in course of time to restore the plants to health and vigour. Meanwhile, by paying every attention to young stock worked up from the old stools it will not take a great length of time to have sufficient of these to gradually replace the worst of the old plants.—PLANTSMAN.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

APRIL 23.

No previous exhibition in the Drill Hall has been so interesting as that held on Tuesday last. It is pleasing to record an excellent attendance of Fellows and others by whom the exhibits were evidently greatly appreciated. The hall was filled to its utmost capacity in every part, leaving none too much room for the inspection of the productions. Such a show as this held in the society's own gardens at Chiswick would be in congenial surroundings, but the exigencies of the times tend rather towards bringing the products as near as possible to the visitors rather than the latter taking a journey to inspect them, as in the old days of Chiswick, the gardens of which have possibly never been visited by one half of the present Fellows.

Every department was fully represented on this occasion both as regards hardy flowers and tender exotics, the former being in greater numbers. Of these hardy flowers, the Daffodils were staged in surprising variety and of the best possible quality,

the colour in several instances seeming to be richer even than usual; hardy Primroses and species of the Primula were likewise staged in large numbers. Most notable of the Daffodils were the large collections from the trade growers, Messrs. Barr and Son and Mr. Thos. Ware, and from such well-known amateurs as Rev. Mr. Engleheart and Mr. Bourne, the former with his own seedlings and the latter with the choicest named kinds in commerce. A most worthy and instructive exhibit came from the Hardy Plant Nursery, Guildford, comprising Primulas of several species with other early flowers, including alpinas; these were set up in a really artistic and natural manner amid pieces of stone, the mossy Saxifrages thus showing to the best possible effect, the whole forming an example that many conservative exhibitors of the old type would do well to imitate. The Primroses shown represented the finest forms from such well-known raisers as Mr. G. F. Wilson and Mr. R. Dean, than which nothing better could be desired. The Auriculas are always in strong force at this meeting, but the impression given was that no real advance is being made. Roses were exceedingly fine, never better in April; not less than thirty large boxes came from such well-known growers as Messrs. F. Cant, Mount, Rumsey, and Walker; whilst of plants there was a grand bank from Mr. Rumsey and a smaller collection from Messrs. Paul and Son. Mr. H. B. May had Crimson Rambler Rose in good form, also one of his characteristic exhibits of Ferns. Amaryllises again came from Messrs. B. S. Williams and Son, representing their excellent strain; whilst from Waltham Cross Messrs. W. Paul and Son sent examples of Evergreens and Coniferae showing the effects of the recent severe winter. The exhibits before the Orchid committee were again numerous, both Chelsea and St. Albans contributing choice groups to the display; whilst several botanical curiosities came from Tring Park and Burford Lodge. The one Orchid in strongest force was no doubt *Cattleya Schroderei* in several exhibits, but of *Cypripedium Rothschildianum* (or otherwise *C. Elliottianum*) there were some fine examples contributed. The labours of the fruit and vegetable committee were again light, the best exhibits being the vegetables and early Grapes from Syon House, first-rate examples of table produce, and the Radishes and Kales from the Reading firm. The first Melon made its appearance in The Countess, a splendid-looking fruit for so early in the season.

#### Orchid Committee.

First-class certificates were given to—

**LALIA-CATTELEYA EPICASTA** (*Cattleya Warscewiczii* × *L. pumila*).—This, beyond doubt, is one of the most chaste and beautiful bi-generic hybrids yet raised, the growth quite intermediate; so also is the flower, the sepals and petals of which are of a deep purplish mauve, the former being in a measure narrow, but the latter, on the other hand, very broad. The labellum is tipped with a much deeper shade of the same colour, almost bordering on that of pure purple, whilst the inner portion has a broad base of creamy white. From Messrs. J. Veitch and Sons, Royal Exotic Nursery, Chelsea.

**CATTELEYA CITRINA**, which, to the surprise of a great number present, had not previously received this well-merited distinction. The example in question was an excellent one, both from point of variety and cultivation, having two large, massive blooms of rich lemon-yellow colour deliciously perfumed. This *Cattleya* comes from Mexico, having been introduced as long ago as 1838. From Mr. H. Grinling, Harrow Weald, Stanmore.

Awards of merit were given to—

**DENDROBIUM FIMBRIATUM SUPERBUM**, in every sense a markedly superior form of this species both in respect to the richer shading, tending towards deep buff in the sepals and petals, whilst the labellum was also not only larger, but of a deeper shade, having also the beautiful mossy fringe strongly in evidence. From Mr. G. Marshall, Claremont House, Grimsby.

**LYCASTE TRIFOLIATA LEHMANNI**.—A singular, yet pleasing form with greenish white sepals, the petals nearly pure white, the lip being deeply fimbriated. The plant shown bore several flowers. From Messrs. W. L. Lewis and Co., Southgate.

**CYPRIPEDIUM GOWERIANUM MAGNIFICUM**.—A very fine form of the type, itself a hybrid closely allied to *C. Lawrenceanum*, which it much resembles in contour and growth, having the dorsal sepal veined with maroon on a vinous purple ground and margined with white, the petals being densely spotted with maroon on a pale green ground, thus pointing to *C. Curtisi* as its other possible parent. From Mr. F. Hardy, Ashton-on-Mersey.

**DENDROBIUM HILDEBRANDI**.—A new species from Burmah with the lip as its chief feature, this being of a clouded sulphur-yellow tinged with green, the same shades, only paler, running into the sepals and petals, which have a faint tinge of purple on the reverse, but are otherwise white; the flowers are of medium size, the growth strong, sturdy and erect. From Baron Schreder's collection, The Dell, Egham.

Botanical certificates were awarded to the following: *Habenaria Bonatea*, an interesting if not beautiful Orchid with pure pale green sepals and petals, and a white lip four times divided, the spike being stout and erect; from Messrs. F. Sander and Co., St. Albans; *Polystachya Ottoniana*, a very pleasing plant of quite miniature growth, bearing a profusion of small white flowers with traces of pale purple, each bloom appearing, as it were, to be inverted; from Sir Trevor Lawrence's collection; *Masdevallia fragrans*, which may possibly only prove to be an older species under a different name; the flowers are of a pale greenish-yellow and decidedly fragrant; from the same source as the last; and *Lycaste gigantea*, with large greenish-yellow flowers and a snuff-coloured lip, deeply fringed; from Mr. Walter C. Walker, Winchmore Hill, N.

Messrs. J. Veitch and Sons had an extensive group, which consisted of several of their own choice hybrids as well as other good things. *Odontoglossums* were represented by *O. cirrhosum*, of which a very fine example with three dense spikes, bearing as many as eight branches to each, being covered with flowers (worthy of a cultural commendation); *O. hastilabium*, with a tall branching spike, in excellent condition, and *O. Pescatorei*. *Oncidium concolor*, one of the best of the dwarf species, had three good spikes. Of *Cattleyas* there were *C. Schroderei*, rich in colour, *C. Schilleriana*, a lovely dwarf species, very distinct, and a good form of *C. Trianae*. *Lalia Cattleya Epicasta* has been described. *Lalia Latona* was again shown, being, if possible, of a richer shade of orange-yellow. *L. purpurata* was also staged in good form, also *L. Schilleriana*, a species seldom seen; it has large flowers with white sepals and petals slightly flushed, the lip being bright purple, the growth tall (this must not be confounded in any way with *Cattleya Schilleriana*, which is quite distinct). Of *Cypripediums* there were *C. ciliolare*; *C. Creon*, with dark lustrous flowers; *C. Haynaldianum*, a very distinct and well-defined species, with many flowered spikes; *C. Brysa*, after *C. Sedeni*, but larger and of distinct colour. Of *Masdevallias* there were to be seen the original and true *M. coccinea*, which later on was known as *M. Lindenii* of gardens; *M. Veitchii* with large blooms, and *M. ignea* in profuse flower. Other good things comprised a lovely white *Cattleya Mendeli* with the labellum comparable to *C. Mossiae Reineckiana*; also *Dendrobium Phalenopsis Schroderei*, with deep vinous purple flowers, and *D. crepidatum*, the deep golden lip of which was very conspicuous. *Maxillaria Sanderiana* bore two very fine flowers and as many buds (a sturdy plant). *Cymbidium Lowianum*, with the good old *Oncidium ampliatum majus* were also sent (silver Flora medal). Messrs. F. Sander and Co. had another choice and varied group, comprising a grand plant of *Dendrobium Auguste Victoriae*, a species from Northern Guinea, of tall majestic growth, bearing several erect, many-flowered

spikes of white flowers; *Dendrobium thyrsoflorum*, bearing very dense spikes of deep colour; *Epidendrum nemorale*, a charming and very distinct species with large pale rosy lilac flowers densely clustered at the apex of the spike; *Thunia Brymeriana*, with the purest possible white flowers, the lip bearing faint lines of pale lilac, the plants very robust. *Odontoglossum crispum*, two very superior forms, void of spots, but faintly flushed with pale rose, the sepals and petals broad; *O. crispum roseum*, a well-defined variety with a deep rosy suffusion; *O. cirrhosum*; *O. hystrix nobile*, with large blossoms of fine form and colour; *Cypripedium macrochilum*, bearing two grand blooms; *Odontoglossum Pescatorei*, a pure white form; *O. triumphans*, of large size and deep colour; *Cypripedium macropterum*, a hybrid, showing traces of *C. Lowianum* or *C. hirsutissimum*, were also sent. *Oncidium Rogersi*, *Masdevallia Veitchii*, *Oncidium sarcodes*, *Cattleya Schroederæ*, *Cologyne Dayana* with two long spikes, *C. tomentosa*, a distinct species with terra-cotta coloured sepals and petals, and *Lælia-Cattleya Frederick Boyle*, a pleasing hybrid with white sepals petals and the lip lightly veined with rosy purple, were also included (awarded silver Flora medal).

Messrs. W. L. Lewis and Co. also exhibited a large and excellent group, which comprised several well-developed varieties of *Lælia purpurata*, both light and dark coloured, showing considerable variation; *Odontoglossum triumphans*, of which a grand form was staged with large massive blooms of dark colour, the sepals and petals unusually broad; and *O. luteo-purpureum*, a good variety of which was included. *O. crispum* was represented by a pure white variety with beautifully fringed flowers. *O. Andersonianum album* and *O. Pescatorei Lewisi* were both capital varieties of the types, the latter being void of spots on the sepals and petals, but with unusually dark markings on the lip. The good old *Leptotes bicolor* was in capital condition. *Cattleya Lawrenceana* and *Lycaste inodora* were both included (awarded silver Flora medal). Messrs. H. Low and Co. showed a good group, in which was a very fine form of *Cattleya Mossiæ*, with the lip of unusual size and of rich colouring (of this species the firm in question possess a very choice variety), the rich golden colour of the lip in this instance partaking somewhat after *C. aurea*. *C. Mendeli* was also represented by a very fine form with a broad, bright crimson-purple lip; *C. Schilleriana* was also to be seen, a lovely *Cattleya*; also *C. Schroederæ*. Of *Cymbidium Lowianum*, an unusually fine variety was staged, the sepals and petals being of a richer shade of yellow with as many as twenty-four flowers to the spike, of which there were three. *Odontoglossum Andersonianum* and *O. triumphans*, with *Vanda Bensonæ*, were also included (awarded silver Banksian medal).

Mr. Pitt, Stamford Hill, showed a nicely-grown collection of well-flowered plants, amongst which were several *Dendrobium thyrsoflorum* in good condition with large spikes. *Cymbidium Lowianum* was also in good form; likewise *Cattleya citrina* and *Dendrobium aggregatum majus*, with large rich yellow flowers supported on quite slender spikes. *Epidendrum atropurpureum* of deep colouring, and its white variety with paler sepals and petals and the lip of the purest white; *Miltonia Roezli*, with large flowers; *Ada aurantiaca* and *Angraecum Sanderianum*, both in good condition; *Cattleya Mendeli*, an extra fine variety; *C. Lawrenceana* and *C. Schroederæ*; *Cypripedium Rothschildianum*, a good plant; *Ornithocephalus grandiflorus*, very singular; *Odontoglossum Ruckerianum* and *O. nebulosum candidulum*, with a fine example of *Phaius Wallichii*, with dark lustrous chocolate flowers, the lip being white, with other good things were also sent (awarded silver Flora medal). Mr. R. J. Measures, Cambridge Lodge, Camberwell, showed a beautiful assortment of *Vanda tricolor*, showing great diversity of colouring and of size; also *V. suavis*, with strong spikes, this species, as it is wont, not varying to any extent. *Angraecum Sanderianum* was represented by a very long

spike, and *Cattleya Loddigesi* by well-developed flowers (awarded silver Banksian medal). Messrs. Heath and Son, Cheltenham, showed several fine healthy masses of *Cattleya Schroederæ*, one named *magnifica* being particularly fine, the lip in this instance being very broad and deeply coloured, a soft blush suffusing the sepals and petals. This plant bore twenty splendid flowers. Other good forms of this beautiful *Cattleya* were included. *Odontoglossum crispum* was represented by a very distinct form, with crimson blotches, and *Phalænopsis amabilis* by a large-flowered variety, the one spike bearing three fine blooms (awarded silver Banksian medal). Messrs. B. S. Williams and Son had *Cymbidium Devonianum*, *Cattleya Schroederæ* and *Cologyne Massangeana*, all in good character; also an exceedingly fine form of *Dendrobium Wardianum*, with flowers 5 inches across, having very broad petals and a large round lip with the inner portion of a deep golden yellow, being one of the finest forms yet seen. *Odontoglossum crispum* was shown well, and so was *Cypripedium Exul*, with well marked flowers, the spots on the dorsal sepal being quite black. *C. Rothschildianum* and *C. vexillarium* were both shown well, the latter clearly showing its relation to *C. Fairricanum*. *Dendrobium superbum* was well flowered, and so was a very healthy piece of *Chysis bractescens*, with very pure blossoms. *Cypripedium Chamberlainianum* was included, being of good colour (awarded silver Banksian medal).

Of other exhibits, Baron Schroeder had *Lælia Digbyana Mossiæ*, one of the most beautiful and unique of hybrid Orchids, being one of the greatest triumphs of the Veitchian firm in this direction. Two choice *Dendrobies* came from the same source. Mr. McNeekin, Falkland Park, Norwood, had a very distinct and superior form of *Odontoglossum Andersonianum* with a clear ground colour spotted with pale chocolate, the spike a good one. *O. Wilekeanum* with *O. Halli*, both capital spikes, and *O. cirrhosum* came from the same source. Mr. Appleton, Weston-super-Mare, had *Epidendrum atro-purpureum album*, in which the lip is of the purest white, and the sepals and petals much paler than in the type, the purple having almost vanished. *Cattleya Schilleriana* and *Cypripedium niveum* came from the same exhibitor. Mr. F. Hardy showed *Cypripedium Godefroyæ* (Hardy's var.), not unlike a small *C. bellatulum*. *Odontoglossum nebulosum candidulum* and *O. n. candidum*, two distinct forms, were included here, as well as *O. Ruckerianum* Mrs. F. Hardy, a choice form, with deep crimson spots on a light ground. Sir Trevor Lawrence had two splendid examples of *Masdevallia Armini* in most profuse flower; this is quite a gem amongst the small forms. A cultural commendation was awarded. *Eria aridostachya*, a very singular Orchid with graceful spikes of small greenish yellow flowers, and *Eria* species, with much larger flowers, more in the way of the smaller *Cymbidiums*, were included, as well as a finely flowered example of *Dendrobium cretaceum* with pure white blossoms, save the lip, which is of a creamy shade and of a downy character. Mr. Walker had a grand variety of *Cattleya Mendeli* called *Walkeriana*, with large flowers of deep colouring, the lip being exceedingly showy, the bright purplish crimson extending into the throat. Other varieties of this species came from this source also two splendid flowers of *Cypripedium caudatum* with the tail-like petals fully 2 feet long. *Dendrobium McCarthiae*, a species seldom exhibited, was also staged in fine condition, the plant being only a small one. A long spike of *Vanda Amesiana* with nineteen flowers was also sent. From Mr. Statter on this occasion came *Cattleya Prince of Wales* (hyb.), *C. Mossiæ Reineckiana* being one of the parents, in which the lip was delicately veined with light purple, the sepals and petals being milky white.

A most noteworthy exhibit, from the fact of its having been sent from Rome, was to be seen from the Prince di Venose's gardens in *Cypripedium Prince di Venose* (*C. villosum* × *C. Lowianum*), in which the former parent had borne a pre-

ponderating influence, traces of the other parent being chiefly seen in the petals. Major Joicey, Sunningdale Park, sent a well-grown plant of *Dendrobium atro-violeaceum* with three spikes of extra large flowers, and another of *Cypripedium Rothschildianum* with two grand spikes, much finer than usual. To both of these a cultural commendation was awarded. *Phaius Blumei assamiensis*, with very dark sepals and petals, came from this exhibitor also. Mr. Lionel Crawshaw had *Odontoglossum mulus* (Rosefield var.) with long spikes of flowers. From Mr. G. Marshall, Claremont House, Grimsby, came *Dendrobium chryso-toxum giganteum*, a truly gigantic form of this beautiful species, three long spikes of which were shown, the flowers being of specially rich colour. *Odontoglossum maculosum* and *Cattleya Loddigesi* came from this source also, as well as *Odontoglossum Andersonianum Victoria*, an excellent form with broad sepals and petals. *O. Halli* was specially good, and so were *O. Marshalli* and a form of *O. Andersonianum*. *O. crispum superbum*, with large pure flowers void of spotting, and *O. baphicanthum*, best described as a large *O. Andersonianum*, with two grand spikes of richly coloured flowers of *Lælia cinnabarina* with fourteen and fifteen flowers and buds respectively to each, were likewise comprised in this exhibit.

#### Floral Committee.

Awards of merit were made to the following:—

**PTERIS CRESTA WIMSETTI.**—Another crested variety of this variable fern, but quite distinct from the several forms already obtained, in which all the crests are terminal. This kind, in addition to its crest at the end of its long narrow leaflets, has lateral-crested leaflets as well, whilst the habit of growth is tall and graceful. Shown by Mr. H. B. May, Dyson's Lane, Edmonton.

**TROPEOLUM COOLGARDE.**—A basket of neat pyramidal specimens of this variety was shown. Its flowers are rich self-yellow, bright in colour, and freely borne. From Mr. H. B. May.

**ROSE MARCHIONESS OF LONDONDERRY.**—A new Hybrid Perpetual variety well shown last year. It has full, well formed white flowers of great size and substance, borne erect on a strong footstalk. From Messrs. Paul & Son, Cheshunt.

**ROSE BRIDESMAID.**—One of the now numerous sports of that good old Tea Rose Catherine Mermet; flowers of the same fine form as those of the parent, but deeper in colour, and keeping the bright pink hue, whereas those of *C. Mermet* fade with age. This also came from Messrs. Paul & Son.

**BOUGAINVILLEA SPECIOSA SUPERBA.**—A variety of this handsome shy-flowering species, with flowers much deeper in colour than those of the type, specimens of which were sent for comparison. From Mr. G. Stanton, gardener to Mrs. Nobbs, Park Place, Henley-on-Thames.

**POLYANTHUS HERMANN.**—A fine variety belonging to the bunch flowered race, with a bold truss on a stout stalk, the flowers considerably larger than those of other blue Primroses, and of a deep violet blue colour more effective by far than the lighter tinted kinds. Shown by Mr. G. F. Wilson, Heatherbank, Weybridge.

**ANDROMEDA FORMOSA,** from Mrs. Ramsden, Guildford, could not be found, so no description can be given.

**DAFFODILS** were quite the leading feature, a very fine group being exhibited by Messrs. Barr and Son. This included the best varieties in all sections. Of the trumpet-flowered kinds, Emperor, Empress, and Horsfield were prominent among older varieties, whilst *Glory of Leyden*, *Weardale Perfection*, and *Mme. de Graaf*, three noble new kinds well shown, are sure to be largely grown in the future. *J. B. M. Camm*, a pale cream-coloured variety, has a flower of good substance. Of star-flowered varieties, *Barri conspicuus*, with rich edged corona, *Orpheus*, *C. J. Baekhouse*, bright orange-yellow, *Maurice Vilmozin*, and *Crown Prince* were all fine. The Leeds varieties were well represented by *Ceres*, a graceful drooping flower, *Superbus*, with a long sulphur corona, *Beatrice*, *Fanny Mason*, and *Duchess of Westminster*, one of the largest and finest of West-

race. *Muscari* in several forms were also shown, *M. conicum* being one of the best, earliest, and most distinct, with long, conical spikes of deep blue flowers. A silver Flora medal was awarded. Mr. T. S. Ware, of Tottenham, received a similar award for a large group consisting chiefly of Daffodils, the arrangement excellent, each kind when several bunches were shown being massed together, a better way by far than the indiscriminate mixing. Emperor and Empress were good, Princess Ida charming, with pale sulphur trumpet, and Barri conspicuous, very effective in quantity. The Leeds varieties were largely represented, Catherine Spurrel especially fine with broad perianth segments and clear yellow corona, Superbus, Grand Duchess, and Beatrice being also good. Among the poetical varieties, ornatus and poetarum were good. *Dielytra spectabilis* at the back and *Anemone fulgens* as a margin in front enhanced the effect of the group. Seedling Daffodils from the Rev. G. H. Engleheart were a most interesting lot, the finest of them all that named Ellen Willmott. The flower is even larger than that of Weardale Perfection, somewhat similar in colour with pale cream petals and rich yellow trumpet, which is short but unusually broad, with a gracefully recurved fringed edge, altogether a noble flower, large without being coarse. Norma and Sir Evan were both fine, with pale creamy petals and trumpets in different shades of yellow. Two deeply coloured seedlings from princeps were of a rich self yellow shade, as rich in colour as *maximus*. If they retain the other merits of the parent they will be decided acquisitions. Princess Mary, of the poetical type, with broad pure white petals and a shallow sulphur corona, was fine, and Torch was a very bright star-flowered variety, with gracefully twisted petals and long crown edged with the brightest orange. Dorothy Yorke, of the same race, with broad shallow corona and pale yellow petals was good. Many unnamed sorts were shown from different crosses, showing that the possibilities of multiplication of varieties are practically unlimited. A silver Banksian medal was awarded. Roses, both in pots and as cut blooms, were largely shown, Mr. W. Rumsey, of Joyning's Nurseries, Waltham Cross, receiving a silver-gilt Flora medal for a large collection of specimen plants in pots, including Souvenir d'un Ami, Niphotos, Mme. Heste, L'Idéal, General Jacqueminot, Marquise de Castellane, and Magna Charta, all in fine form, and cut flowers in quantity, of Niphotos, The Bride, Souvenir d'un Ami, Souvenir de S. A. Prince, Maréchal Niel, and other well-known kinds. Messrs. Paul, Chesnut, showed Roses in pots, Elise Fugier, like a pale cream Niphotos, being noteworthy. Mme. Hoste, Catherine Mermet, Bridesmaid, Clara Wat-on, Marchioness of Londonderry, Danmark, Paul's Early Blush, Gustave Piganeau, Jeannie Dickson, and Carmine Pillar, all new or comparatively recent kinds, were well shown. A group of Cannas also contained some nice kinds as Progression, fine yellow with dark spots, Chesnut Yellow, a rich self, and Tom Thumb, a dwarf kind with red yellow-edged flowers. A silver Flora medal was awarded. Mr. F. Cant, of Colchester, staged a fine lot of cut Roses, both Teas and Hybrid Perpetuals, Ethel Brownlow, Mme. Hoste, and Mme. Cusin of the former, and Mrs. John Laing and Caroline Testout of the latter being the finest. A silver Flora medal was awarded. Mr. G. Mount, of Canterbury, received a similar award for a good collection of cut Roses, chiefly Teas, showing boxes of such grand kinds as Catherine Mermet, The Bride, Niphotos, and Maréchal Niel, with numerous other varieties in smaller numbers. Mr. J. Walker, Thame, Oxen, showed Roses Maréchal Niel and Niphotos in large quantity, the flowers very fine. He received a silver Banksian medal, Mr. J. C. Tasker, of Brentwood, receiving a similar award for a group of pot Roses arranged with *Azalea mollis* and *Adiantums*. The group of hardy flowers chiefly *Primulas* from the Guildford Hardy Plant Company was most interesting and instructive, the method of ar-

range so natural, and a great advance upon the conventional way of showing things. Choice and lovely alpine *Primulas* nestled among little rocks just as they might in their mountain home. *P. nivalis* was covered with its snowy clusters of flowers, and *P. marginata* in several forms was beautiful, its white margined tufts of leaves as pretty as its clusters of pale mauve flowers. *P. auricula*, *P. ciliata* in variety, *P. mollis*, *P. denticulata*, *P. farinosa*, and numerous other rare and pretty kinds were shown, also *Androsaces*, *Soldanellas*, *Epimedium niveum*, *Trillium erectum*, and a fine specimen of *Haberlea rhodopensis*. A silver Flora medal was awarded. Mr. G. Jackman, of Woking, was awarded a bronze Flora medal for a pretty mixed group of Daffodils, tufted Pansies, double *Primroses* in six distinct kinds, *Primulas* in variety, and other interesting hardy flowers. A large group of Ferns, Palms, and other fine foliaged plants from Mr. H. B. May, Dyson's Lane, Edmon-ton, received a silver Flora medal. The crested and other forms of *Pteris* were well represented, also *Adiantum Farleyense*, *Tropaeolum Coolgardie*, previously described, and two well-flowered specimens of Rose Crimson Rambler were conspicuous. Mr. B. S. Williams, of Upper Holloway, showed a group of *Amaryllises*, the best kinds Empress of India and President Faure, deep crimson, Colonel Kelly and Lord Valentia, light red, and Dr. Koch, white feathered with red. A fine lot of *Leschenaultia* was also shown, a bronze Flora medal being awarded. Mr. Reynolds, of Gunnersbury Park Gardens, received a bronze Banksian medal for an excellent group of *Primula obconica*, the plants most profusely bloomed, the trusses and flowers individually of large size; a really fine exhibit of this well-known plant.

From the Royal Gardens, Kew, came a group containing many species of *Primula*, rare and well known kinds, *Androsaces*, several pretty little species; *Amberstia nobilis*, cut specimens of this showy Indian tree noted elsewhere, and *Cineraria cruenta*, a pretty species with small flowers in large clusters covering the plant. Messrs. J. Veitch & Sons, Chelsea, showed blue *Primroses* in quantity, the varieties G. F. Wilson, John Gibson, Covenanter, and Elizabeth Brodie being all of a blue shade, the last named with violet blue flowers of a rich tone. *Alyssum saxatile citrinum*, which received an Award of Merit last year, was again well shown, the plants hidden in the wealth of flowers which are lemon yellow and much paler than those of the type. Mr. F. Cornish, gardener to Lady Bowman, Joldwynds, Dorking, was given a cultural commendation for *Epigaea repens*, the plants shown pictures of health, each shoot terminated by a cluster of its sweet white flowers. Sir Trevor Lawrence had some very fine Daffodils of the varieties Emperor, Horsfieldi, and Sir Watkin, also *Primula Forbesi* and *Primroses* in variety. Miss Mason, Norton Hall, Retford, showed the Florentine form of *Tulipa sylvestris*, *Soldanellas*, *Androsace carnea* and *Anemone vernalis*. *Salix lanata*, sent by Mrs. Robb, Goldenfield, Liphook, is a pretty Willow with woolly leaves and catkins. Mr. McMeekin, Falkland Park, Norwood, sent two seedling *Rhododendrons*, and from Messrs. W. Paul & Son, of Waltham Cross, came a large group of coniferous and other evergreen trees and shrubs, "to show the effects of the frost," which, as regards those shown, were of a negative character, only the tips of *Laurustinus* being browned, whilst the common Laurel, that is in a deplorable state nearly everywhere, was shown with leaves scarcely discoloured.

The exhibits competing for Mr. Barr's special Daffodil prizes were very fine indeed, and probably no finer group has ever been staged than that from the Rev. S. E. Bourn, Dunston Vicarage, Lincoln, which was deservedly awarded first prize. There were over 100 varieties, including all the finest, *Glory of Leyden* being represented by a bunch of eleven flowers, whilst Mme. Plomp and Mme. de Graaf were well shown. Other trumpet kinds included Emperor, Empress, Horsfieldi, P. R. Barr, Michael Foster, Maximus, Queen of Spain, Cernuus, Albicans, Tortuosus, and J. B. M.

Camm. The best of the yellow star varieties were Figaro, Gwyther, Barri conspicuous, C. J. Baekhouse, Flora Wilson, Beauty, and Maurice Vilmorin. In the Leeds section Duchess of Westminster was the best, Duchess of Brabant, Fanny Mason, Palmerston, Catherine Spurrel, Minnie Hume, and Beatrice all good, and of Burbidge varieties John Bain and J. Stevenson noteworthy. A charming freshness characterised the whole lot. Mr. J. T. Bennett Poë was second with an admirable lot, Mr. Cammell, of Billingshurst, third, and Mr. W. J. Grant, Bassaleg, Newport, fourth.

#### Fruit Committee.

This was one of the most interesting meetings held this year. The collections of Borcoles and Radishes from Messrs. Sutton, Reading, deserve more than passing notice after the severe winter.

A first-class certificate was awarded to—

**TOMATO ALL THE YEAR ROUND**, a very free-growing variety, bearing large clusters of medium-sized fruit, ten to twelve in a bunch, and of very good flavour for the time of year. The fruit was shown on stems cut from the plants, the growths being 3 feet to 4 feet long, with eight to ten bunches of fruit. This is certainly one of the most prolific and free-setting varieties grown. From Mr. W. Farr, The Gardens, Spring Grove House, Isleworth.

Awards of merit were given to—

**IMPROVED HEARTING KALE**.—The name is well merited, the examples being much superior to other hearting varieties—firm, solid, beautifully curled and of dwarf growth. From Messrs. Sutton and Sons, Reading.

**EARLIEST FRAME RADISH**.—This is a distinct break from the ordinary kind, earlier, of better shape than any of the Radishes we have for forcing, and of a rich crimson colour. It is very solid and grows to a nice size in a very short time. Out of some two dozen sorts exhibited this was noticeable for its colour and good qualities. From Messrs. Sutton and Sons, Reading.

Messrs. Sutton also contributed a very fine collection of Kales, no less than twenty-four distinct variegated kinds being staged. The colours ranged from dark purple to nearly white. The useful Sutton's Favourite Kale was also well shown, this being a hardy dwarf kind of Asparagus Kale, of delicious flavour when cooked and not running to seed till late in the spring. Messrs. Sutton also sent no less than twenty varieties of Radishes. These were staged in their sections—the forcing and long-rooting kinds being apart and forming a most instructive exhibit. The red and white-tipped Turnip varieties and large Crimson were very fine. Among the olive-shaped varieties mention must be made of Sutton's Forcing, noted above; Earliest of All, the roots as large as a good Filbert with scarcely any top; Forcing Carmine, very dwarf and of good colour; Crimson Forcing, scarcely any top, a grand forcing variety; Fern-leaved, an oval root with distinct Fern like leaves; The Gem, or White-tipped, a small root, but fine for salad; Golden Olive, a novelty for summer use; Scarlet Globe, a very fine type and of splendid quality; Long White and Long Rose, very handsome long-rooting kinds and of excellent quality. Two very fine Countess Melons were sent by Mr. Meads, The Gardens, Buscot Park, Faringdon, Berks. Mr. G. Wythes, The Gardens, Syon House, Brentford, received a cultural award for a nice lot of Foster's Seedling Grapes from year-old Vines. The berries were well finished and of good flavour. From the same exhibitor was sent a very fine lot of new Potatoes, Sharpe's Victor, well meriting the cultural award given. Mr. Wythes also sent a very fine dish of Seakale; this, grown in the open ground, was merely covered with soil, and was of very good quality. The Horticultural College, Swanley, sent the new Royal Sovereign Strawberry packed in market punnets, the fruit very good, of excellent quality. From the same source were sent Sir Joseph Paxton Strawberries, nice fruits and well coloured. Mr. Goldsmith, Leonardlee Gardens, Horsham, sent his new

Apple Burfield Seedling, a nice looking fruit of great merit. This was thought to be a good market fruit, and the grower was requested to report on its cooking qualities next meeting, many of the committee thinking it a valuable keeping variety. From Messrs. B. S. Williams, Holloway, was sent a dwarf French Bean bearing good-sized pods. The committee requested it to be sent to Chiswick for trial.

## NOTES OF THE WEEK.

**Iris orchoides.**—We send you by post a few spikes of *Iris orchoides* cut from the open border, where the bright yellow flowers have been a great attraction for some time past.—R. W. WALLACE.

**Epimedium niveum** is a charming little species, shown on Tuesday. It has close tufts of leaves and slender spikes of pure white flowers. It is a gem for a choice spot in the rock garden.

**Ranunculus splexicaulis** was shown in Mr. Jackman's interesting group at the Drill Hall. It is a pretty species from the Pyrenees, with slender stems each about 1 foot in height, bearing large flowers of a pure white colour with a little tuft of yellow stamens in the centre.

**Primula mollis.**—Among many *Primulas* at the show on Tuesday this was conspicuous, a well-grown example being shown by Mr. J. Douglas. It has broad, Vine-like leaves, thickly covered with soft hairs, and hairy flower-stems, which grow about 1 foot high, with blooms of a deep rose colour in several whorls.

**Amherstia nobilis.**—Some fine sprays of this Indian flowering tree were shown at the Drill Hall on Tuesday from the Royal Gardens, Kew, and attracted much notice. The flowers are borne in a long drooping raceme, and are of a soft vermilion red colour. Large specimens in flower must have a gorgeous effect.

**Narcissus incomparabilis fl. pl. ponderosus.**—A remnant from an old Irish garden, what is known as "Butter and Eggs," but in its ponderous form. If the plants had had some rain a month since the flowers would be a size larger. It is quite the admiration of all visitors to Ard Cairn, and so distinct.—W. BAYLOR HARTLAND, *Ard Cairn, Cork.*

**Tulipa præcox.**—This fine early Tulip, now flowering, although botanically not distinct from *T. oculus-solis*, is more robust and better in every way. It has large, long petalled flowers, borne on a strong, erect stem 1 foot high, of a soft red shade externally, bright red inside, with conspicuous black blotches, margined with yellow at the base.

**Fritillaria Kotschyana affinis.**—This, as shown by Mr. Barr at the Drill Hall on Tuesday, is a beautiful kind, and a welcome addition to a family which, though numerous, does not contain many species of much beauty in gardens. It will be a charming companion to *F. aurea*, which it resembles in size and shape of flower, but its colour is most distinct, a dark crimson externally, brighter inside with yellow markings.

**Pansy Blue Gown.**—Dr. Stuart thinks this is one of the best varieties he has raised, and rightly so. It is one of the earliest kinds to flower and a long, persistent bloomer. We have groups of all the best varieties, but whilst most kinds as yet have only a few flowers out, the group of Blue Gown is already quite a mass of lovely colour. It will certainly be a popular garden Pansy when better known.

**Hedysyrum multijugum.**—This delightful flowering shrub, introduced from Northern China, has proved perfectly hardy here at Exeter, and should be in every garden. It is deciduous and prefers light soil in a sunny position, where it attains about 1 yard in height when fully developed. The flowers, which appear about July, are very freely produced and are in long, loose

racemes of deep purplish crimson colour.—F. W. MEYER.

**Carpenteria californica.**—This fine shrub, referred to in the last issue of THE GARDEN, has proved hardy at Exeter without any protection during the past severe winter. During previous winters it retained its green foliage all the year round, but the present season has transformed it into a deciduous shrub. The leaves, which were shrivelled by the severe frost, have fallen off, and the plant is rapidly making new growth.—M.

**Cercus sinensis pendula rosea.**—This highly ornamental flowering tree seems very little known. Some very fine specimen standards are now in full bloom at Messrs. Veitch's nursery, Exeter, and present a lovely picture. The long slender branches have a graceful drooping habit, and are covered with bright pink blossoms resembling those of *Malus floribunda* when seen from a distance, but appearing much earlier than those of that tree.—M.

**Haberlea rhodopensis** was shown in fine form at the Drill Hall on Tuesday by the Guildford Hardy Plant Company, the specimen having eighteen strong flower-spikes bearing from three to five flowers each. The flowers are like those of a small *Gloxinia*, of a pale lilac colour, deepening to dark blue at the base. It has large, green, hairy leaves, which form perfect rosettes, is quite hardy and flourishes under conditions that suit the *Ramondia*. A coloured plate of it was given in THE GARDEN of August 28, 1886.

**Roses in the north.**—While reading of the great destruction of Roses by frost during the past severe winter I do not see many which are entirely destroyed. Those trained on arches have suffered most. Dwarfs planted with the junction of scion and stock well under the surface are little the worse. I would like to hear how William Allen Richardson has stood. Here half-a-dozen plants, all of which were planted out, are killed. One plant at the end of a cool Peach house, and allowed to grow almost wild, is loaded with flowers.—M. TEMPLE, *Carron, N.B.*

**Triacodonta hexapetala** (better known as *Crinodendron Hookerianum*).—This fine evergreen shrub has proved quite hardy in the gardens of the Earl of Annesley at Castlewellan, and has been flowering for the past few weeks. The large campanulate flowers are of a rich carmine colour, and remain on the plants for weeks before dropping off. At Castlewellan it is growing in a shaded border in peat and loam. The largest plant is about 5 feet in height. In a less favoured climate than Castlewellan it would be advisable to give a little protection in very severe weather.—T. RYAN.

**Franciscea Hopeana.**—Mr. Hudson (p. 280) has done well to call attention to this neglected and almost unknown plant. I have a moderate-sized specimen of it here which is now literally covered with its sweet-scented flowers, and is greatly admired. The peculiar way the flowers have of changing colour makes it a very interesting plant. I also have *F. magnifica* associated with it. This also has been in bloom for weeks and is likely to continue so for some time to come. What a pity it is that these and other stove flowering shrubs are not more generally grown.—J. EASTER, *Nostell Priory Gardens.*

**Rhododendron fulgens.**—I read with much interest your note on this very beautiful shrub in last week's GARDEN. Mr. James Bateman has just flowered it most successfully in his garden at Home Lodge, Worthing, within a few score yards of the sea. One very large and one small head of flower were in full beauty during Easter, and were the produce of quite a small plant, which, like that at Kew, has sustained no ill effects from the past severe winter. This splendid plant is figured in Sir Joseph Hooker's "Rhododendrons of Sikkim Himalaya," plate xxv., but even that most carefully executed plate fails, in my opinion, to convey an adequate impression of the richness of the blood-red flowers.—W. ROULETS.

**Rhodothamnus Chamæcistus** (syn., *Rhododendron Chamæcistus*).—This diminutive alpine

shrub has not suffered in the least from the severe winter. In the rock garden at Messrs. Veitch's nursery, Exeter, a pretty specimen is now in full bloom. The flowers, large for so small a plant, are of a lively pink colour and borne in clusters of three, each individual bloom being fully an inch in diameter. The plant in question was planted about three years ago; it is now scarcely 3 inches in height and 6 inches in diameter, but its small bright green leaves, which are deeply serrated, are crowded so densely together as to represent a compact evergreen cushion, which was in itself an ornament all through the winter. The position is a half shady one, and the soil, sandy peat and loam, seems to suit it admirably.—M.

**Erica carnea.**—This charming little moor heath is one of the very few species (even of our native ones) that appear to have passed through the recent winter without more or less injury—at any rate, in the neighbourhood of London. *E. vagans* and *E. cinerea*, both natives of Britain, are badly cut back, but *E. carnea*, inhabiting practically the same latitude, is scarcely affected. It is a close-growing dwarf plant, which produces its purple-red flowers in the greatest profusion during the early spring months. This is a late season and the neat tufts are now at their brightest. As a plant for forming an edging to borders or beds of American plants it has no superior. It may be planted in a formal strip, but a much more pleasing effect is made by it in informal groups or masses of varying size and width.

**A note from Liphook.**—I send you a bunch of mauve *Primroses* off a root I dug up on the shores of the Bosphorus last year. They have lit up the border here for some time past, and the plant appears to bear more flowers here than in its native wilds. The different shades caused by the deep colour of the buds among the paler expanded blossoms are striking in this species, and it has been much admired. The severe winter has been evidently a tonic to some things, e.g., *Daphne Blagayana* and the *Megaseas* I have never seen so full of bloom. In some years the latter are mostly all leaf and little flower, now it is, in fact, the reverse, and the pink bloom stands up so tall and fine that people have wondered what it could be until they came up close to the plant. *Saxifraga Malvi*, *Draba Brunoniata*, *Hydrangea stellata*, and *Puschkinia litanotica* have all been remarkably gay. I wonder the last is not oftener seen, as it is perfectly hardy and good-natured and has a very fascinating effect in the early bleak time of year.—M. A. R., *Liphook.*

**Reports of shows.**—The reports of the Royal Botanic Society and the National Auricula Society are unavoidably held over, and will appear in our next issue.

**The weather in West Herts.**—A week of very growing weather, both the days and nights having been warm for the month. At 1 foot and also at 2 feet deep the ground is now about 2° warmer than at the beginning of the week. At the depth of 1 foot the temperature of the soil is at the present time 5½° higher than the April average for the previous nine years, and 2° warmer than at the same time last year. Welcome rains have fallen during the week to the aggregate depth of nearly half an inch. A wild Cherry tree came first into blossom in my garden on the 23rd inst., which is its average date of flowering for the previous nine years, but three weeks later than last year.—E. M., *Berkhamsted.*

**Names of plants.**—*F. M.*—Probably *Lælopius dominicensis*.—*C. S. V.*—*Glonera jasminoides*.—*Thomas May*.—*Forsythia suspensa*.—*S. N. T.*—1, *Anemone apennina*; 2, *Ranunculus anemonoides*; 3 and 5, *Anemone blanda*; 4, *Dicentra eximia*; 6, *Saxifraga purpurea*.—*Erin.*—1 and 3, *Narcissus arantius plenus*; 4, *N. incomparabilis* variety; 5, *N. maximus*; 6 and 11, single and double *Jonquil*; 8 and 10, forms of *Narcissus tazetta*; 9, *N. cernuus*; 12, *Sir Watkin*; 13, *Horsfieldi*; 14, *N. princeps*; 15, *Tulipa florentina*. Several of the numbers having got detached, there was no clue to the name. We only undertake to name four varieties in one week.

No. 1224. SATURDAY, May 4, 1895. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHIDS.

## ONCIDIUM MACRANTHUM.

No one who has seen this Orchid in good condition can fail to be struck with its beauty and elegance, the richly-coloured flowers so jauntily set upon the long branching scapes giving it a most distinct appearance. It is, unfortunately, too often the custom to tie these scapes round and round stakes placed in the pots, thereby quite dwarfing its beauty. To obtain the best effect, this *Oncidium* when in flower must be grouped with Palms or large Ferns, the flower-scapes hanging loosely and naturally among the foliage, the pots being, if possible, hidden from view. This makes the most delightful background for a group of Orchids imaginable. Of course, while the spikes are growing they need some support, but this may usually be managed by tying a string from a stake in the pot along the roof, securing them loosely to this. This does not cripple or bend the spikes unnaturally, yet keeps them safe from injury in other ways. Another way in which this *Oncidium* shows to good effect is upon a shady wall lined with Ferns, the plants being put in position at the time of planting the Ferns. This way of growing Orchids is not much practised, growers being apparently under the impression that the requisite attention cannot easily be given without the usual pots, baskets, or blocks. This is, however, a mistake, as I have lately proved, and I hope to say a little on this mode of culture shortly. *O. macranthum* is comparatively easily grown, but a few of the more salient points of its culture may perhaps be noted with advantage. When compared with the size of the pseudo-bulbs the flower-scapes are very large, and in order to produce and sustain them over a considerable period the plants are called upon to put forth a great deal of energy. To maintain this, they naturally push strong feeding roots, which must be carefully protected, as they are very often emitted above the surface of the compost. If the atmosphere were always congenial, possibly these would be quite as well left uncovered, but with our best care there are times when a lack of moisture or other essential will occur and the roots may suffer. Insects, too, are fond of these thick fleshy roots, and instinctively find them if exposed. A little Moss should be placed up to these roots, which should be encouraged to push into and through it to the compost below. If this is rough and light with nothing of a sour, close character about it, they will find ample sustenance among it and the drainage, the health of the plants being improved in a marked degree. *O. macranthum* is a very restless Orchid, frequently growing through the winter months, and for this reason the plants should never be subjected to a very low temperature or dried at the roots, neither is this necessary to promote free-flowering, the most vigorous plants being also the freest flowering. No Orchid is more easily affected by drought in the atmosphere, and if thrips are introduced by this means the evil is intensified, free growth being then out of the question. Periodically immersing in water for an hour or two and immediate spongings are advisable, the insects by these means being driven from their

hiding-places in the compost. This, as hinted above, should consist largely of charcoal and potsherds, the layer of peat and Sphagnum being only superficial. The climbing habit of this species renders it necessary to set the base of the plant rather low in the pot, filling up to around it with the crocks and charcoal. The temperature advised for the warmer section of *Odontoglossums* will suit it admirably, and during summer the plants must be somewhat heavily shaded. The flowers of a good typical form would be about 4 inches across. The sepals and petals are narrow at the base, becoming nearly round, crisped and wavy at the edges. The former are brownish yellow, the latter deep golden yellow; the lip small, singular in shape and colour, with a prominent raised crest. Introduced from New Grenada in 1867, it now takes a high position in this splendid genus, and when well grown is one of the most magnificent Orchids in existence. H. R.

## GONGORAS.

ALTHOUGH not commonly grown, the dozen or more species belonging to this genus are very interesting Orchids, many of them extremely free-flowering, the blossoms being in nearly all cases fragrant. They are all epiphytal pseudo-bulbous Orchids, easily grown in the *Cattleya* house or in an ordinary plant stove. The strong-growing kinds thrive in rather large baskets or suspended pots, their pendent racemes showing to advantage in this way. The compost for these may consist of equal parts of peat and Sphagnum Moss and a little charcoal. Abundance of water is required during the summer, and the syringe must be freely plied about the plants to keep red spider in check, this pest soon disfiguring the foliage if left undisturbed. During winter they must be kept rather drier at the root and given a light and airy position. The temperature must, however, be kept fairly high and rather moist, as the plants are susceptible to injury from cold or drought, a kind of black spot attacking the leaves and pseudo-bulbs, which is very disfiguring. Scale is occasionally troublesome, and must be kept in check by sponging, this also improving the appearance and health of the foliage if carefully done.

*G. ATRO-PURPUREA* is perhaps the most generally grown, and a very free-flowering species. The blossoms are produced on long pendent racemes from the base of the pseudo-bulbs, which are light green, deeply ribbed, and each bears a pair of lanceolate leaves. It is a native of Trinidad, and frequently flowers all through the summer and autumn, as soon as one spike is over another being produced. About a dozen deep reddish-brown, profusely-spotted flowers are usually produced on each raceme.

*G. BUFONIA* (the Toad-skinned Orchid) is a singular and variable species, the pseudo-bulbs and leaves very light green; the racemes are long and pendent, the flowers dull brownish purple. The variety major has larger flowers, while *leucochila* is much lighter, with a white lip. These are all natives of Brazil, and flower in spring and early summer. A species named

*G. CHARLESWORTH* was introduced by Messrs. Charlesworth, Shuttleworth and Co., and exhibited by them at the Temple show two years ago. It is a strong growing kind, and has whitish flowers with purple markings.

*G. FULVA* is a strong growing kind, the flowers resembling those of *G. bufonia*, being produced on long, elegant racemes. This and its variety *vitellina* are said to be natives of Peru and Guatemala.

*G. ODORATISSIMA* comes from Venezuela, and has large flowers of a deep lemon-yellow, blotched with red.

*G. TRICOLOR* is a fine species, somewhat similar to the last-named, but with a good deal of white about the lip. It produces long pendent racemes of flowers in early summer, and is a native of Central America.

*G. TRIMCALO* is a native of Mexico, and has pendent racemes of light yellow and purple-spotted flowers, which at a little distance may easily be taken for insects of some kind. The perfume of this Orchid is greatly disliked by some people, but tolerated by others.

There are several other species in this genus, and amateurs and others who like peculiar and grotesque flowers will find much in them to admire, while the few simple details of culture that are requisite need not deter the least experienced. R.

## ODONTOGLOSSUMS FOR AMATEURS.

THE most suitable Orchids for amateurs with only a limited amount of space at command are *Odontoglossums*. In this family may be found much variety, whilst some kinds take a front rank amongst Orchids. The majority are most successfully grown with cool treatment in a temperature that ranges from about 45° to 70°, the lowest temperature being for the winter months, and the other, or as near that as can be maintained, during the summer; the night temperature should generally fall about 5° less than that stated. *Odontoglossums* enjoy a considerable amount of shade and moisture, but the light must not be excluded; therefore it is advisable to have roller blinds fixed so that they can be let down when the sun is powerful. Water must be supplied during the whole year, but much more is needed both at the roots and in the atmosphere in the summer months, when also a good supply of fresh air will be found most beneficial, care being taken to avoid cold draughts. The pots should be well drained, clean, and not too large for the plants, which should be potted annually either early in autumn or early spring, well elevating the plants above the rim, and using a compost of about equal parts of fibrous peat and Sphagnum Moss, with a few nodules of charcoal, all well mixed together. *Odontoglossums* are natives of Central and South America, most of the species being found in New Grenada, Mexico, and Costa Rica, where they always grow at considerable elevations, seldom less than about 7000 ft. above the sea level. Some of the most beautiful and most easily grown kinds should find a place in every collection, for they are not only very useful for decorating the conservatories and grouping with other plants, but their blooms are serviceable for cutting. One of the most popular Orchids is *O. crispum* and its numerous varieties, which are extensively grown in every country at the present time for market work, the cut spikes being in great demand for coat flowers, bouquets, &c. This kind is popularly known as *O. Alexandre*, and produces long arching racemes of many flowers at all seasons of the year. The flowers, measuring from 2½ inches to 4 inches in diameter, range in colour from pure white to a rosy mauve tint, and are often more or less spotted with red. During recent years this kind has been extensively imported, and may now be purchased at a trifling cost. Another gorgeous kind is *O. grande*, but it will not succeed under the treatment above mentioned. It is a native of Guatemala, and enjoys during the winter a warmer and somewhat drier temperature, similar to that at the coolest end of the *Cattleya* house. It should be given a more pronounced season of rest. The flowers, the largest of any in the genus, measuring fully 6 inches across, are of a bright yellow colour, the sepals and petals barred and blotched with chestnut-red. *O. Rossi* is a very dwarf-growing species, producing its flowers in abundance. These are usually white or of a pale rosy shade, having the sepals and petals spotted with brown, the large lip being quite clear. Of this kind there are many fine varieties now in

existence, and these succeed best when suspended in shallow pans close to the roof. Similar treatment is also best for *O. Cervantesi*, another fine dwarf species, with pure white flowers 2 inches across, and having some broken lines of chocolate-red running transversely around the base of each sepal and petal. *O. triumphans* produces its flowers freely during the early months of the year. They are golden yellow, spotted and barred with cinnamon-brown, the fine white lip having also a large blotch of the same colour. Of *Odontoglossum luteo-purpureum*, probably the most variable species, we have quite a large number of forms. All, however, are worth growing, as they produce long racemes of flowers and are very showy. The ground colour in most instances is yellow, with blotches and spots of deep brown. This is found in its natural habitat growing in the same districts as *O. crispum*, at about 8000 feet or 9000 feet altitude, and much resembles the latter when not in bloom, but is generally of somewhat larger dimensions. There with many others should find great favour with amateurs on account of their simple requirements and great beauty, especially as they can be grown at much less cost than many of the East Indian and other heat-loving plants. A few more desirable kinds that can be mentioned are *O. polyxanthum*, *O. Insleyi*, *O. maculatum*, *O. bictonense*, and *O. citrosimum*. The last is one of the most distinct kinds known and another exception to the general rule, requiring the heat of the *Cattleya* house, with plenty of air and light shading. When at rest it must be kept quite dry, even if the bulbs shrivel. This will cause the plants to bloom more freely, and the pseudo-bulbs will soon recover and become plump when moisture is applied. It should be repotted shortly before it starts into growth, and is seen to the best advantage when suspended from the roof in either pans or baskets. The flowers, which are numerous, each measure about 3 inches in diameter: the sepals and petals white, sometimes flushed with rose, whilst the lip is usually of a bright deep rose. It is a native of Mexico, and one of the most attractive species.

WM. HUGH GOWER.

### LARGE SPECIMEN ORCHIDS.

ALTHOUGH decried in some quarters, there can be no question as to the beauty of large well-cultivated Orchids, and those who declaim most against miserable looking starvelings that have only bulk to recommend them are often the most lavish with their encomiums when confronted with beauly well-flowered plants no matter what their size. Large plants of most kinds, however, need large spacious structures to grow in, and as the predilection of present-day growers is for smaller houses, the return to favour of large specimen plants is thereby hindered. It is often the case, too, that in order to make room for new purchases the fine old plants that have for years given a good account of themselves are gradually elbowed out. In many otherwise well-managed gardens one comes across a house, perhaps an old vinery or greenhouse, wherein are grouped in a more or less chaotic condition plants of all kinds, relics of former days—Palms that have done more than their duty at the mansion, old-fashioned hard-wooded plants turned out to make room for present-day favourites, and many others—which the gardener usually describes to his visitors as a miscellaneous lot, and passes on to inspect the aforesaid favourites. So it is with Orchids. A hamper of new plants comes from the nursery or a consignment of newly-imported plants from the sale rooms; the houses are already full, and something must go into a corner, the choice often falling on some fine old *Vanda*, *Saccolabium*, or other would-be noble subject, room being wanted for the pigny *Cypripedium* or *Odontoglossum* from

which so great things are expected. It would be the height of folly to advise a whit less attention being bestowed on them, but a deep-rooted liking for the former plants prompts these few lines on their behalf. A suggestion that has frequently been made, but not sufficiently taken advantage of, is the adaptability of vineries to the growth of large Orchids. This is, I am aware, very distasteful to many fruit growers who like "the vinery for the Vines," and conjure up possibilities of mealy bug and other insects in galore; but how much of this is prejudice or alarm will be shown by the good results attending the practice where judicious management obtains. If there are successional vineries it is comparatively easy, without in any way injuring the Vines, to give the Orchids a suitable temperature and atmosphere all through the year by shifting them to the various compartments as this is necessary. It is not intended in this note to go into the details of culture, as these will suggest themselves and must vary according to circumstances, but simply to recommend growers who have these conveniences and find it necessary to relieve the pressure on their Orchid houses to remove thereto any of the grosser growing kinds. This will have the double advantage of giving the smaller plants more room and the large species a more congenial home.

H. R.

**Chysis bractescens.**—In THE GARDEN for April 15 in an article on *Chysis*, "H. R." says that *C. bractescens* sometimes has as many as six flowers on one raceme. You will find enclosed raceme has eight flowers, and the bulb that it has come from is 16 inches long. Let me know if that is an unusual number.—T. HEYWOOD, *Wellfield, Bury Lam.*

\* \* It is not usual for *Chysis bractescens* to produce eight flowers upon a raceme. The flowers, however, are not usually of full size when more than six are produced. A very fine variety I flowered several years in succession bore flowers each nearly 6 inches across, but never more than three upon the raceme, although the growth was very vigorous.—H. R.

**Cattleya Lawrenceana.**—I believe this beautiful *Cattleya* is flowering more freely than usual this spring. Possibly its culture is now becoming better understood. I grow the plants in a brisk and moist heat, conditions this species apparently likes. But what a range in the size and colour of the flowers. One plant which I have is far superior to the others, the individual blooms being very large and brilliantly coloured; in fact, the colour of the lip extends to the sepals.—A. YOUNG.

## ROSE GARDEN.

### SPRING VERSUS AUTUMN PLANTING OF ROSES.

HOWEVER strong the opinion may be in favour of planting Roses in the autumn, there is no doubt that the success of the operation depends more on the character of the weather prevailing during the winter than has been generally acknowledged. The past winter has proved this, for here in the west of England in the majority of cases quite half the plants set out in the autumn were killed by the prolonged cold weather. So far as my experience goes this is no exception, for in the early winter of 1891 and 1892 the frosty weather came on before I could complete the planting of a number of standard and bush Roses. The result was that I had more dead plants in the

following summer amongst those that were put out before the frost set in than amongst those that were laid in by their heels for several weeks and planted in the month of March. This is sufficient to convince me that spring planting has its advantages, and if I had to perform the same kind of work again in a heavy soil and bleak situation I should certainly wait until the spring before I planted Hybrid Perpetual Roses in any form. Of course, Teas and other tender Roses would be dealt with at the same time. When I was a youth I had to assist in taking up every autumn all the Tea Roses occupying several beds, and store them away in a well-sheltered corner, with some dry Bracken stuffed between the branches to prevent the frost from reaching them. When all danger of hard frost was past in the spring the plants were transferred to the beds again. Of course, under such a system we did not get very early flowers, but we saved the plants, and that is more than I have done this year with those left in the ground undisturbed, although the roots and stems were well protected with coal ashes, and even those that are alive are so terribly weakened, that half of the summer will be gone before they show any degree of vigour. There is a great deal of unnecessary prejudice existing in the minds of some people against laying in by their heels Roses that come to hand at a time when it is not convenient to plant them. I do not mean to say that I would always prefer laying them in to planting them at once, but when there are indications of severe weather approaching I am convinced it is better to place the roots in some fine earth in a snug corner, laying a little dry litter on the branches, than to put them in their permanent quarters where they will be exposed to all the rigours of a long and severe winter. In the winter I have just referred to, as well as during the one just past, I had a number of both standard and dwarf plants laid in by their heels with the stems and branches protected by litter, and although the soft tops were injured by the frost, ninety-five per cent. of the plants are alive and doing well. When laying in Roses by their heels, the main point is to see that the roots are well covered with fine soil pressed firmly about them. As showing the lateness of this season as compared with some others, on a white Banksian Rose that was in flower at the end of March two years ago, the buds are not even now showing a trace of colour, although I am writing on April 21. A plant of Fortune's Yellow is just as late in blooming, while the old Pink Monthly, which is generally so early, is hardly forward enough to show the flower-buds.

J. C. CLARKE.

Taunton.

**Roses and the past winter.**—After a season in which many losses have been sustained in the Rose garden, it would be interesting as well as advantageous to Rose growers if lists of those which have best stood the severity of the weather were given in the pages of THE GARDEN. Some years ago, after a very severe winter, many plants died off during May and June.—T.

**Roses in Sussex.**—In my garden, where there are about 350 Roses, I have only lost three; in one part where there are 160, not one has been killed, and 90 of these are Tea Roses. Forty were planted late in November. We had 20° of frost and the average for February was 9° of frost. We had not more than four inches of snow, the ground for four weeks being covered with about two inches. I also hear from all my neighbours that their Rose trees have not suffered so much as usual. Daffodil bulbs are certainly weakened, some clumps not flowering at all and it is the same with some of the Tulips.—A. S., *The Firs, Bexhill-on-Sea.*

## FRAGRANCE.\*

A MAN who makes a garden should have a heart for plants that have the gift of sweetness as well as beauty of form or colour. And what a mystery as well as charm—wild Roses sweet as the breath of heaven, and a wild Rose of repulsive odour, all born of the earth-mother, and it may be springing from the same spot. Flowers sweet at night and scentless in the day; flowers of evil odour at one hour and fragrant at another; plants sweet in breath of blossom, but deadly in leaf and sap; Lilies sweet as they are fair, and Lilies that must not be let into the house; with bushes in which all that is delightful in odour permeates to every March-daring bud. The Grant Allens of the day, who tell us how the Dandelion sprung from the Primrose some millions of years ago, would explain all these things to us, or put long names to them—what Sir Richard Owen used to call “conjectural biology.” But we need not care where they leave the question, for to us is given this precious fragrance, happily almost without effort, and happily as free as the clouds from man’s power to spoil.

Every fertile country has its fragrant flowers and trees; alpine meadows with Orchids and mountain Violets; the Primrose-scented woods, Honeysuckle-wreathed and May-frosted hedgerows of Britain; the Cedars of India and of the mountains of Asia Minor, with Lebanon; trees of the same stately order, perhaps still more fragrant in the warmer Pacific breezes of the Rocky Mountains and Oregon, where the many great Pines spring from a carpet of fragrant Evergreens, and a thousand flowers which fade away after their early bloom, and rest in the heat, while the tall trees overhead distil for ever grateful odour in the sunny air; Myrtle, Rosemary and Lavender, and all the aromatic bushes and herbs clothing the little capes that jut into the great sea which washes the shores of Greece, Italy, Sicily and Corsica; garden islands scattered through vast Pacific seas, as stars are scattered in the heavens; enormous tropical forests, little entered by man, but from which he gathers on the outskirts treasures for our Orchid houses and greenhouses; island gardens like Java and Ceylon and Borneo, rich in spices and lovely plant life; Australian bush, with traces of plant life as if from another world, but often most delicate in odour even in the distorted fragments of them we see in our greenhouses.

It is not only from the fragile flower-vases these sweet odours flow; they breathe through leaf and stem, and the whole being of many trees and bushes, from the stately Gum trees of Australia to the sweet Verbena of Chili. Many must have felt the charm of the strange scent of the Box bush before Oliver Wendell Holmes told us of its “breathing the fragrance of eternity, for this is one of the odours which carry us out of

time into the abysses of the unbeginning past.” The scent of flowers is often cloying, as of the Tuberose, while that of leaves is often delicate and refreshing, as in the budding Larch, and in the leaves of Balm and Rosemary, while fragrance is often stored in the wood and down through the roots.

Flowering shoot of *Chimonanthus fragrans*.

It is given to few to see many of these sweet plants in their native lands, but we who love our gardens may enjoy many of them about us, not merely in drawings or descriptions, but the living, breathing things themselves. The Geraniums in the cottage window bring us the spicy fragrance of the South African hills; the Lavender bush of

the sunny hills of Provence, where it is a home; the Roses in the garden bring near us the breath of the wild Roses on a thousand hills; the sweet or pot herbs of our gardens are a gift of the shore-lands of France and Italy and Greece. The Sweet Bay bush in the farmer’s or cottage garden comes with its story from the streams of Greece, where it seeks moisture in a thirsty land along with the wild Olive and the Arbutus. And this Sweet Bay is the Laurel of the poets, of the first and greatest of all poet and artist nations of the earth—the Laurel sacred to Apollo, and used in many ways in his worship, as we may see on coins, and in many other things that remain to us of the great peoples of the past. The Myrtle, of less fame, but also a sacred plant beloved for its leaves and blossoms, was, like the Laurel, seen near the temples of the race who built their temples as Lilies are built, whose song is deathless, and the fragments of its art Despair to the artist of our time. And thus the fragrant bushes our gardens may entwine for us, apart from their gift of beauty, living associations and beautiful thoughts for ever famous in human story.

It is not only the odours of trees and flowers known to all we have to think of, but many delicate ones, less known of, perhaps, by reason of the blossoms that give them being without showy colour, as the wild Vine, the Sweet Vernal, Lemon, and other Grasses. And among these modest flowers there are none more delicate in odour than the blossoms of the common white Willow and yellow-twigged and other Willows of Britain and Northern Europe, all the more grateful in air coming to us.

O’er the northern moorland, o’er the northern foam.

What is the lesson these sweet flowers have for us? They tell us—if there were no other flowers to tell us—that a garden should be a living thing; its life not only fair in form and lovely in colour, but in its breath and essence coming from the Divine. They tell us that the very common attempt to conform their fair lives into tile or other patterns, to clip or set them out as so much mere colour of the paper-stainer or carpet-maker, is to degrade them and make our gardens ugly and ridiculous, from the point of view of Nature or true art. And many of these treasures for the open garden have been shut out of our thoughts owing to the exclusion of almost everything that did not make showy colour and lend itself to crude ways of setting out flowers to compete with tiles and like modes of “decoration.”

Of the many things that should be thought of in the making of a garden to live in, this of fragrance is one of the first. And, happily, among every class of flowers which may adorn our open-air gardens there are fragrant things to be found. Apart from the groups of plants in which all, or nearly all, are fragrant, as in Roses, the annual and biennial flowers of our gardens are rich in fragrance—Stocks, Mignonette, Sweet Peas, Sweet Sultan, Wall-

\* First written for McDonald’s “Sweet-scented Flowers.” London. 1895.

flowers, double Rockets, Sweet Scabious and many others. These, among the most easily raised of plants, may be enjoyed by the simplest cottage gardeners. The garden borders of perennial flowers bear for us odours as precious as any breath of tropical Orchid, from the Lily of the Valley to the Carnation, this last yielding, perhaps, the most grateful odour of all the flowering host in our garden land. In these borders things are sweeter than words may tell of—Woodruff, Balm, Pinks, Violets, garden Primroses, Polyanthuses, Day and other Lilies, early Irises, Narcissi, Evening Primroses, Mezerion and Pansies delicate in their sweetness.

No one may be richer in delicate fragrance than the wise man who plants hardy shrubs and flowering trees—Magnolia, Thorn, Daphne, Lilac—names each telling of whole families of delightful things. Among shrubs, those without any strong odour, like hardy Heaths, are welcome to many who are often touched by remembered fragrance of some plant they do not always know. From the same regions where we found the Laurel and the Myrtle we have the Laurustinus, beautiful in all our sea-coast and milder districts, and many other lovely bushes happy in our climate: one, the Winter-Sweet, even pouring out delicious fragrance in mid-winter: Sweet Gale, Azaleas, Allspice, and the delightful little Mayflower that creeps about in the woodland shade in North America. So, though we cannot boast of Lemon or Orange groves, our climate is kind to many lovely and fragrant shrubs.

Even our ugly walls may be sweet gardens with Magnolia, Honeysuckle, Clematis, Sweet Verbena, and the delightful old Jasmine, still clothing many a house in London. Most precious of all, however, are the noble climbing Tea Roses raised in our own time, within the past fifty years or so. Among the abortions of this century these are a real gain—the loveliest flowers ever raised by man. Noble in form and colour, and scented as delicately as a June morn in alpine pastures, with these most precious of garden Roses we could cover all the ugly walls in England and Ireland, and very many of them are in want of a veil.

The old way of having an orchard near the house was a good one. Planted for use, it was as precious for its beauty, and not only when the spring winds carried the breath of its myriad blossoms of Cherry, Plum, Apple, and Pear. There were the fruit odours, too, and the early Daffodils and Snowdrops, with Violets and Primroses on the banks came, and overhead the lovely hardy trees that bear our orchard fruits, Apples, Pears, Cherries, Plums, Medlar and Quince. To make pictures to last round the year and far along them I should ask for many orchard trees on a few acres of good ground (all the better if too uneven for the plough): a rough belt of native Evergreens, Hollies, Yew and Fir on the cold sides to comfort trees and men; and with careless garlands of Honeysuckle, wild Rose, and Clematis among them

here and there, and in the bank fence plenty of Sweet Brier, and May, and Sloe.

The fence would not be cut every year into a bare and ugly line, but May, Sloe and Sweet Brier left to bud and bloom, and the bank and hedge to form a shelter as well as a strong fence—not to be touched oftener than every ten years or so, and then when dealt with it should be woven together in the strong way usual in parts of Kent, that is, strong and tough enough to keep back an elephant. On the cool side of these sod banks the Primrose and the Oxlip would bloom long and well, and on all sides of them Daffodils and Jonquil, with Snowflakes, Snowdrops, wild Tulips or any bulb-like thing we had to spare from the garden; and from the garden clippings, too, a few tufts of Balm and Myrrh to live for ever among the Grasses of the bank and below the wreaths of Honeysuckle.

W. R.

## STOVE AND GREENHOUSE.

### PELARGONIUM CULTURE.

THE fact that the old enthusiasm for the culture of show and fancy Pelargoniums has to a great extent subsided is not easily accounted for, as it would be difficult to name any class of soft-wooded flowering plants more attractive or useful during the months of May and June. At one time in almost every garden of any pretensions there was a batch of show Pelargoniums which were kept by themselves and treated in a special manner, the blooming season being watched with more than ordinary eagerness. Anyone accustomed to visit the metropolitan shows twenty years ago will not readily forget the gorgeous specimens exhibited by Mr. John Ward, of Leyton, and which I suppose have never been equalled by those of any other grower.

One of the first to improve the Pelargonium was Mr. Beck, a slate merchant, of Isleworth, who raised many new varieties, some of which would be hard to beat even at the present day. Amongst others might be named Desdemona and Mare Antony, the former a light flower with a purple blotch and a prodigious bloomer, the latter of a darker shade and equally as free. Old exhibitors will remember these varieties. To grow Pelargoniums well a fair amount of skill and great regularity are necessary, and for this reason they are best kept by themselves. The best compost for the plants is loam cut from a pasture the reverse of rich containing a large percentage of fibre. A rich loam, especially if manure is added, is very apt to produce a sappy growth, which should be avoided. To the loam should be added in autumn short stable manure well soaked with urine, stacking layer by layer. After it has been stacked some weeks and the manure has become decomposed, the heap should be chopped down and the ingredients well mixed. It should then be removed under cover and kept dry till wanted, sufficient rough sand being added at potting time to keep it open.

After the plants have done flowering water should be withheld for a few days, after which each shoot should be cut back, leaving only a few eyes at the base of each. No water must be given till the wounds heal over, when the plants may be daily moistened with the syringe to induce them to break again into growth.

When the shoots are half an inch long the plants should again be allowed to dry at the ball previous to shaking them out and removing all the soil from the roots. The main roots should be cut well back and all the fibrous ones left intact, after which the plants should be potted into as small pots as will hold them, using loam and sand free from manure. If a frame is at command a sufficient quantity of leaves should be placed therein to produce a gentle bottom heat. In this plunge the pots, moistening the ball and keeping the frame close and shaded until the plants are again established, which will be in a week or ten days. After this more air should be admitted until the lights are entirely removed in the daytime, the great aim being to keep the new growth dwarf and stiff and to induce rest. On the approach of frost remove the plants to a light airy greenhouse, keeping them as near the glass as possible. From this time to the middle of January no more water should be given than is required to keep the shoots from flagging, abundance of fresh air being admitted in fine weather by both the top and bottom ventilators. About the third week in January is a good time to put the plants into their blooming pots, draining well and using the compost first named; pot firmly, returning the plants to the greenhouse, again keeping them rather close and shading for a week should the weather be bright. As growth advances syringe the foliage overhead when the house is closed early on sunny days, fumigate on the first signs of aphid, and stop the shoots according to the time the plants are wanted to flower. If required for exhibition, train the shoots directly they become sufficiently pliable, and always smoke the house immediately before the first flowers open. Stimulants ought not to be supplied until the bloom-trusses appear, as if the plants are healthy and strong they frequently flower unsatisfactorily if rich food is given before that date. Although not lasting so long as some flowers when cut and placed in water, they are most useful for that purpose, and plants in bloom, if placed in a frame behind a north wall or hedge and elevated on bricks so as to allow of a free current of air passing amongst them, will remain in full beauty for a considerable time. Diluted sheep manure water suits Pelargoniums best.

J. CRAWFORD.

**Asparagus deflexus.**—As regards this variety of the Asparagus, there seems to be a little confusion. I have noted at Kew that a variety is there grown under the name of *A. decumbens*, which some will have is identical with *A. deflexus*, but in my opinion this is not so. The latter has a sturdier habit of growth, the leaves are more densely set upon the stem, being also a trifle longer, and a shade deeper of green pervades the entire plant, whilst the same drooping graceful habit is still retained. To my way of thinking, *A. deflexus* is superior in every way to *A. decumbens*. The one may only be a varietal form of the other, but that there is a most perceptible difference is quite evident to those who have had an opportunity of making the comparison. Be this as it may, there is no question as to the usefulness of *A. deflexus* as a basket plant or for planting out in ferneries on overhanging pieces of rock where its long growths can hang down without hindrance. It will withstand quite a cool temperature when established. During the past severe and prolonged winter it kept well in every way in a temperature of from 36° to 40° at night during the coldest spells. As a basket plant for the conservatory or fernery it is well suited.—H. G.

**A new race of Begonias.**—In conjunction with some members of the tuberous-rooted section,

*B. socotrana* has already given us those beautiful flowering varieties, *Adonis*, *John Heal* and *Winter Gem*; and now it has been employed with *B. Rex* in the production of a totally different class, one member of which received an award of merit when shown at a meeting of the Royal Horticultural Society on November 27 last year. The variety so honoured out of several that were shown by Messrs. Sander, of St. Albans, was named *Winter Queen*, and very bright and effective it was at that dull season of the year. The foliage is very ornamental, and, in addition, the infusion of *socotrana* blood has resulted in flowers vastly superior to those borne by *B. Rex* and of a pleasing pink tint. The markings of the leaf vary a good deal in the different varieties,

cannot be successfully amalgamated; if it be done, the plant so treated is bound to suffer in both directions. Should it have been grown on quickly by more frequent shifts, it will never withstand the variations of temperature concurrent on being used in apartments for two or three days together. The cause of this is the want of a hardened growth consequent on not being grown in relatively small pots. *Crotons* that are confined at the roots, but potted in good soil, will withstand a deal of rough treatment and remain in a healthy state for a long time. It will be quite useless, however, to attempt afterwards the task of building up a thriving specimen out of such material, the constitution having become in a measure hardened, but not of likely after development. An

advantage be more often grown than they are now-a-days, for the blossoms of many of them are very beautiful. *E. tuberculatum* is in general appearance very different from most of the others, as it forms a little shrubby specimen with a profusion of branches clothed with small oval leaves of a brownish green tint. The branches are studded with curious little tubercles, from whence the specific name is derived. These tubercles at a superficial glance appear very like a quantity of scale insects, but on closer inspection their true nature is apparent. It is just now flowering freely, the blossoms being pure white and with a long, slender tube somewhat after the manner of *Bouvardia Humboldtii*. The mouth of the flower is over an inch across.—H. P.

The blue Throat-wort (*Trachelium caeruleum*).

and in the case of *Winter Queen* the leaves are much undulated and consist of a star-shaped centre of dark olive-green, surrounded by a belt of silvery grey; while on the outside of the leaf is a broad belt of bright green, dotted with white, altogether forming a very pleasing combination. *Begonias* of this group certainly promise to be a very useful class, and no doubt before long they will be generally distributed in gardens. The hybrid *Begonias* now in cultivation are the product of a great number of widely different combinations.—H. P.

**Decorative Crotons.**—By this expression of the adjective it is the intention to convey the difference between a plant that is being grown on with some degree of rapidity, so as to obtain a specimen plant, and that of one destined to be turned to account for furnishing purposes outside of the stove itself. The two methods of treatment

apt illustration may be taken from the pigmy trees as grown by the Japanese gardeners when contrasted with others of the same kinds that are being advanced under generous treatment. These facts should be borne in mind by all who grow *Crotons* for furnishing. Too humid an atmosphere, too high a temperature, and too free a use of shading will all tend to failure as far as it pertains to this kind of stock. As far as shading is concerned, none at all is required for well-established plants. Shading will not be conducive to colour such as one aims at securing in *Crotons*. Until the pots are thoroughly well filled with roots it is never safe to make use of *Crotons* in unfavourable situations.—H. G.

**Eranthemum tuberculatum.**—This *Eranthemum*, which was introduced from New Caledonia over thirty years ago, is not a common species; indeed several members of the genus might with

### THE THROAT-WORT.

(*TRACHELIUM CAERULEUM*.)

It is only fitting in these days, when too much dependence is placed upon subjects that are chiefly remarkable for their showy properties, to draw attention to this comparatively modest plant. Those who are in search of a plant that will do good service from the middle of August (or sooner if need be) until the end of September (if kept back under a north wall) cannot do better than turn their attention to the plant in question. It is of the easiest possible culture, the old shoots being quite safe in a cold frame through the winter. Some authorities deem it, however, a hardy plant, but this term may, perhaps, have to be modified in some measure if we have a recurrence of such severe winters as the past. It may be propagated in the spring by cuttings taken from the base close to the soil, some of which, it is quite possible, will have roots of their own. Such as these will make capital plants to flower the same season in 6-inch pots, being afterwards cared for to grow on the following spring, so as to provide a set of larger plants if need be. Seedlings can also be readily raised, but when this plan is adopted I would advise the sowing of the seed from plants that have flowered comparatively early in August as soon as it is ripe. This plan will provide a better plant than if spring sowing be adopted, it being possible to keep a goodly number of seedlings in a shallow box or pan through the winter months in a cool greenhouse. In any case this plant may be treated as being as hardy as *Chrysanthemums* from cuttings, or even more so, there being no need of house room from the end of March until the flowering season comes round. For large conservatories this but little-known plant will do specially good service at a season when any novelty is a pleasing change. The best trusses of violet-blue flowers are produced on the terminals, but the lateral shoots on strong plants will also yield a very good display. Scarcely any insect will cause trouble when close attention to watering and syringing is given, which in either case may be liberal. The soil in which I have grown my plants is loam and leaf-mould with a little sand, potting being done in a fairly firm manner. Of this blue Throat-wort there is also a white variety, but I much prefer the type to this varietal form, which is not really so effective. It should be noted that spring-struck cuttings will make dwarfer plants than the seedlings.

SOUTHERN.

**Streptosolen Jamesoni.**—This is a beautiful flowering plant for the greenhouse, and though of very easy propagation and culture, it was, singularly enough, lost soon after its introduction into this country in 1850. It was then unknown, except from botanical specimens, till M. André found it in Ecuador in 1882, and introduced it into France. After that it soon became generally grown, but

certainly not more than its merits deserve, as the distinct orange-red flowers are borne in great profusion and a succession is also kept up for a considerable time. This *Streptosolen* is nearly related to the *Browallias*, and is indeed included in that genus by many authorities. In colour at all events it is quite distinct, for most of the *Browallias* have blue flowers. Though the flowering season of this *Streptosolen* is spread over a considerable period, it is, I think, seen at its best in spring and early summer. I have met with it in better condition and in greater quantity in many places this year than formerly, and it is certainly a plant that pays for a little extra attention. In too dry an atmosphere red spider is apt to cause the foliage to turn yellow and drop, but no other insects give much trouble.—T.

#### PALM SEEDS.

Now that Palms are far more popular than was at one time the case, large importations of seeds frequently reach this country, and immense numbers are disposed of at the London sale rooms. The recent announcement of a forthcoming sale of over half a million seeds has suggested a few notes on the subject, for most Palms require rather different treatment from that given to the seeds of other classes of plants. The selection of Palms generally grown for ordinary decoration is not an extensive one, the most commonly met with being the *Kentias*, *Latania borbonica*, *Cocos Weddelliana*, *C. flexuosa*, *Seaforthia elegans*, *Areca lutescens*, *A. Baueri*, *A. sapida*, *Phoenix rupicola*, and *Corypha australis*. Palm seeds as a rule reach this country in better condition than was at one time the case, and now out of some importations nearly every seed will germinate. It is very necessary to examine the seed, for in numerous cases when the germ has perished it will be found that the body of the seed is as firm as ever. A stove is a very suitable place for raising Palm seeds of all kinds, and if they can be plunged in a gentle bottom heat, so much the better. They will germinate all the more readily if previous to sowing them they are soaked for twenty-four hours in water at a temperature of about 80°. The pots, pans, or boxes in which the seed is to be sown should be fairly, but not excessively drained and filled with a soil composed principally of good loam and sand, lightened if the loam is too heavy by an admixture of well-decayed leaf mould or peat. All manures or stimulants of any kind, though valuable later on, should in this early stage be avoided. In sowing, the soil should be pressed down moderately firm, and overcrowding the seeds must be guarded against. They should be covered with soil to about their own depth and plunged in a little bottom heat; no further attention than watering will be necessary till the seeds germinate. Until this takes place the pans or boxes may be stood under the stages or in any out-of-the-way spot, but there is far more probability of their being overlooked, and perhaps suffering from extremes of drought and moisture than if they are plunged in a bed with a gentle bottom heat. Frequently in the case of Palms the seed germinates in a very irregular manner—that is to say, a few will at times make their appearance soon after sowing, while many of them will not grow till some time later. As Palm seeds that reach this country have of course been ripened some time before, and have perhaps undergone many hardships, they should on receipt be sown without any unnecessary delay, as it may make all the difference between a good and a bad crop. When the young plants make their appearance a very good time to pot them off is just as the first leaf is developed, for the roots then soon start in the new soil, whereas if they are allowed to grow larger before potting they are very liable to suffer a good deal from the removal. Small pots should be chosen for the first potting, as most Palms are very impatient even when large of a mass of soil around the roots. A compost such as that in which the seed was sown will, if passed through a sieve with half an inch mesh, do well for the young plants. Of course such free growing subjects as *Latania borbonica*, *Areca lutescens*, and

*Seaforthia elegans* will need even at first larger pots than the weaker growers represented by *Cocos Weddelliana* and *Geonoma gracilis*. In most cases the seed remains attached to the young plant, and it then furnishes a good guide as to the depth the seedling should be placed in the soil at the first potting. As a rule it should be so situated that the seed just rests on the surface of the soil. If plunged in the stove and a good moisture-laden atmosphere be maintained, the young plants of such kinds as are above enumerated will make good progress. They must be kept in a steady growing state and repotted when necessary, for though many Palms will do wonderfully well in small pots, yet if once allowed to become stunted it is very difficult to induce them to grow freely again. As a great deal of the beauty of a Palm consists of the symmetrical manner in which the foliage is disposed, it will be particularly necessary to guard against overcrowding, and the plants must also be turned around occasionally to ensure a well-balanced specimen. Liberal syringing will keep down insect pests to a very great extent, the greatest trouble being scale, which, if allowed to effect a lodgment on the leaves, is very difficult to eradicate. As the plants get larger and reach a decorative size occasional stimulants will be of service, and it is also very necessary to keep the foliage clean. H. P.

#### FOUR GOOD NEW SOLANUMS.

MONSIEUR GEORGES BRUANT, of Poitiers, Vienne, France, the well-known introducer of new plants, is now offering for the first time at such extremely moderate prices as to put them within the reach of all lovers of novelties the following four new species of *Solanum*, most if not all of which should, I think, be great acquisitions to British gardens. M. Bruant describes them as follows:—

*SOLANUM SEAFORTHIANUM* is a native of the Antilles. It has climbing stems with pinnatifid leaves having nine to eleven leaflets, and produces inflorescences of large dimensions in pendent bunches, which afford by their shape and size the appearance of bunches of *Wistaria sinensis*. On each bunch may be counted about forty agreeably perfumed flowers of a delicate and beautiful shade of lilac-blue with golden yellow anthers. The plant is free blooming and of easy culture, and may be used for training up the rafters of a greenhouse or to a wire or light timber trellis in a pot.

*S. DAMMANNIANUM*.—A large and very ornamental species for planting out during the summer. During the course of a single season this plant forms a small pyramidal tree of about 9 feet in height, with large woolly leaves gracefully serrated. In the autumn bunches of large deep blue flowers with golden anthers appear at the extremity of every branch; the plant is then very beautiful.

*S. MOIS ELEPHANTUM*.—A species recently introduced from Equatorial Africa by Dr. Stuhlmann. It reaches about a yard in height with violet stems and deep green foliage. The flowers are large and of a light blue colour, to which succeed large fruits of a canary yellow colour which hold themselves upright and are produced in threes. These fruits are, it seems, very injurious to elephants, hence the name of the plant.

*S. DUBLOSIANUM*.—This very beautiful species has been recently introduced from Abyssinia. It is a plant of robust habit of growth and of easy culture in an ordinary greenhouse; it is well suited also for planting out during the summer or for pot culture if preferred. The foliage is particularly elegant, and the whole plant highly ornamental with large blue flowers set off by golden yellow stamens. The berries which succeed the flowers are pure white in colour. Since writing the above descriptions, translated from M. Bruant's new catalogue, I have found two portraits of *Solanum Seaforthianum*, the one on plate 504 of the 8th volume of Andrew's *Botanical Repository* and the other on plate 1982 of the 45th volume of the *Botanical Magazine*. These pictures represent a distinct and different plant

from the one described by M. Bruant, with numerous small pale, rosy flesh-coloured flowers, and it is stated that the plant was introduced as far back as 1804. It is also said to be synonymous with *S. venustum*, and is also figured in *Botanical Register*, vol. 12, plate 969, and in *Loddiges' Botanical Cabinet*, vol. 10, plate 971; but while the two first cited plates agree as to colour the two latter totally differ from them, being of the palest shade of lilac-blue. It remains therefore to be seen which brace of plates is the correct representation of M. Bruant's plant.

W. E. GUMBLETON.

#### AZALEA HENE.

THIS variety belongs to the small-flowered group of greenhouse Azaleas, and is the only one that has been illustrated in *THE GARDEN*, where a coloured plate was given August 6, 1892. It was raised by M. Otto Forster, of Lehenhof, from that well-known variety of the Indian section *Duc Adolph de Nassau*, fertilised with the pollen of a good form of *Azalea amœna*, the result being a very pretty small-flowered Azalea. It retains the hose-in-hose character of *A. amœna*, but, as might be expected, the flowers are larger than in that kind, and in colour they are a very pleasing bright rosy purple and borne in great profusion. Azaleas of this class are now numerous, and many of them are very valuable for the embellishment of the greenhouse at this season or even earlier, for they respond well to gentle forcing. The rage for huge blooms is, however, still pretty general, and by many freedom of flowering, good habit, and other desirable qualities are of small moment compared with the size of bloom. When the public taste in this respect alters we shall doubtless see this class of Azaleas more appreciated than it is now. The idea of crossing the little *A. amœna* with some members of the Indian section would seem to have originated with Mr. Carmichael when at Sandringham, and many of the varieties raised by him are still grown. The best known of the Sandringham varieties are William Carmichael, Duke of Connaught, Princess Beatrice, and Mrs. Carmichael. The variety of the Indian group principally employed by Mr. Carmichael in the production of his hybrids was that free-flowering form *Stella*. Of small flowers other than that of European raised hybrids we have the typical *A. amœna*, and particularly its variety *Caldwelli*, with larger blossoms than the normal form, the Japanese *A. calyciflora*, whose hose-in-hose blooms are of a bright salmon-red colour with a distinct orange shade, and the little *A. obtusa* with orange-red flowers. Of this last there is a variety whose blooms are white or occasionally striped. Azaleas of this group are very readily propagated from cuttings, and plants so obtained are more satisfactory in all ways than those increased by grafting. The cuttings should be formed of the young shoots taken just as they commence to lose their succulent character, and being dibbled firmly into well-drained pots of sandy peat must be kept close till rooted. In structures where it is difficult to maintain heat during the winter these small-flowered Azaleas will be found useful, for the hardy *A. amœna* being one of the parents, they are, as might be supposed, less liable to be injured by severe weather than the members of the Indian section. The various forms of this last are, however, not all equally tender, for the old white *A. indica alba* is hardy in some places. H. P.

**Early-flowering Magnolias.**—There are at present three kinds of Magnolia in bloom—two species and a hybrid. Although they cannot, unfortunately, be described as amongst the never-failing pleasures of spring—the flowers are too frequently injured by frost—they attain to perfection often enough to well deserve the space they occupy in the garden. Their beauties, too, are all the more welcome and appreciated because of their somewhat uncertain continuance. First amongst the three in importance is the Yulan (M.

conspicua), one of the early introductions from China, and one of the most lovely of all hardy trees. Its dark leafless stems are now laden with the erect cup-shaped flowers, the vivid white of which is all the more effective where it has a background of some Evergreen or even of a group of our native deciduous trees. Very similar to the Yulan in general aspect is the hybrid *M. Soulangiana*; this variety has as one of its parents *M. obovata*, and inherits from that species the purple stains on the outside of the flower. In size of both tree and flower, however, it is equal to the Yulan. Completing the trio is the charming *M. stellata* or *Halleana*. This is a dwarf shrub and commences to bloom when only a few inches high. When small it may be grown in groups or beds, and if the ground between the plants is occupied by some flowering bulbs like the *Chionodoxa*, or *Grape Hyacinth*, flowering at the same time, a most lovely combination is produced. This *Magnolia* grows large enough, however, to stand as a single specimen, as may be seen by the fine rounded bushes, 4 feet high, in the Coombe Wood nursery. A sheltered position should if possible be selected where other and hardier vegetation gives protection from light frosts and from the morning sunshine that so often follows. It is a native of Japan.—B.

## BOOKS.

### INJURIOUS INSECTS.\*

WE have, as usual at this time of year, to welcome another report of observations on injurious insects by Miss Ormerod. This is now the eighteenth year in which she has published these reports. The present one contains observations on thirty pests. Of these twenty-one are insects, three mites, four eelworms, one springtail, and one millipede. Of these, nine—namely, six insects, one mite, one eelworm, and one springtail, are mentioned for the first time, so that the number of pests reported on last year was considerably less than in the few previous ones. This should not be a matter of surprise, as every year our knowledge of the pests which attack our crops becomes more perfect. This report is a very interesting one, and contains much valuable information, but, as in previous reports, it is by no means easy to get at it. With judicious editing it might with much advantage have been much reduced in size and the information it contains given much more concisely without omitting a single item. The pagination of this report is somewhat peculiar; the preface is paged 1 to 7, the actual notes of observations 1 to 118, the appendix 1 to 62, and the index 1 to 3. Why four sets of numbers are used instead of numbering the pages straight through does not appear. Protest must be made against the practice of calling caterpillars which feed on the leaves of trees and plants grubs. There is some excuse for calling some of the caterpillars which feed at the roots of plants grubs, but when alluding to the larvae of the eyed hawk moth, to speak of them as grubs, "but with great grubs like these"—see page 3—twice again on the same page. Also on page 5 the caterpillars of the lappet moth are spoken of as grubs. Ignorant persons like some of her correspondents may speak of caterpillars as grubs, but they would equally understand what was meant if the word caterpillar was used, and in a work of this kind care should be taken to call things by their right names. Miss Ormerod mentions in the preface that no less than about 140 different kinds of insects and other pests have been sent to her with inquiries during last year. A list is given of 70 of the most important attacks; and, speaking of these attacks, she says: "During the past season of 1894 nearly all our common kinds of crop and orchard insect

pests were present, but no attacks were reported as being prevalent generally over the country to a serious extent, or, excepting in the case of the antler moth, over large districts, and the attacks not previously recorded as present were all of importance." An appendix of 62 pages is devoted to the ox-warble, about which in the preface Miss Ormerod says: "The great point of attention, however, of the year has been ox-warble. We (that is those concerned) have been working on constantly, steadily, and with good results, and especial advance has been made in attention to the subject in Ireland. So long as the simple directions, which we have kept well before cattle owners for the last seven years, we do well. But I am bound, though with much regret, to lay before all concerned that there is a great cause for being on the alert against advice claiming to be authoritative, yet in which well proved, easily practicable, and almost costless treatment is left unnoticed and inefficient application advised." The first three insects reported on, the eyed hawk moth (*Smerinthus ocellatus*), the lappet moth (*Gastropacha quercifolia*), and the large tortoise-shell butterfly (*Vanessa polychlora*), can hardly be considered as garden or farm pests. Their caterpillars, like all others, injure to some extent the plants or trees on which they feed, but they are not at present, and there is no record of their ever having been present in sufficient numbers to be really injurious. It is suggested that perhaps "with these, as with other occasional infestations of large and handsome caterpillars sometimes of rare species and usually not very numerous, it would often be the best way towards getting rid of them to let some neighbouring collector of entomological specimens know of their presence." The large tortoise-shell butterfly is one of our handsomest insects, and very rarely occurs in such numbers that the word "injurious" can be properly applied to it. After mentioning the best means for their destruction, the authoress seems struck with remorse, for she says in conclusion "but generally speaking the large and beautiful insects are so scarce, that they might be left uninjured with little fear of consequences. The antler moth (*Charax graminis*), whose caterpillars feed on the roots of grass, and where present, as they are at times, in very large numbers, they completely destroy the grass over a large district. They are most abundant on the hill pastures in the north of England and the south of Scotland. Last year they did much mischief in many places. The caterpillars were often infested by a parasite, one of the hair or threadworms belonging to the genus *Mermis*. These worms are 7 inches and even 8 inches long, and only of the thickness of a piece of fine twine. They are also subject fortunately to a disease which causes the greater part of the interior of the body to turn into a brown liquid containing bacteria. The best means of destroying this pest is by firing the grass. The Hessian fly grubs were not much in evidence last year, only three observations on them having been sent in to Miss Ormerod. One of the insects mentioned for the first time in these reports is the caterpillar of a moth belonging to the genus *Miana* (probably *M. expolita*), which is classed in the division of moths called *Nocturina*. "The caterpillars were observed early in the year doing serious injury to a field of young wheat near Lymington, in Hampshire, by feeding in the centre of the plant and also to some degree eating the young leaves round the centre." One point in connection with the attacks of this insect which is satisfactory is that they were only found in "ley ground," so that it is probable that the eggs were laid at the roots of the grass which was ploughed in, and they afterwards attacked the young wheat. If this be so, there is not much fear of its becoming a very common pest. One of the most important reports is that on the eelworms which injure Hop plants. Professor Percival, of the South-Eastern Agricultural College, Wye, has been making some observations on Hops which have become what is commonly called "nettle-headed," a disease which appears to be on the increase, and the cause of which

was unknown. Professo. Percival finds that the disease is caused by eelworms infesting the roots. Apparently there are two kinds which injure the Hops much in the same manner. The stem eelworm (*Tylenchus devastatrix*), a well-known species which causes "tulip-root" in Beet plants and stem sickness in Clover, and the Beet eelworm (*Heterodera Schaechti*), which is found at the roots of various plants on the Continent, but which had not hitherto been detected in England. Miss Ormerod has published in this report some of the main features of Professor Percival's discovery, but a full account of them is given by himself in the March number of "Natural Science." Miss Ormerod suggests that eelworms may not be the only cause of the abnormal growth, for she says "the same or a very similar kind of diseased growth may be caused by various other attacks or diseases," and she suggests sulphate of potash or sulphate of potash and sulphate of ammonia as remedies, or the more radical cure of digging up and destroying the affected plants. Prof. Percival says, with regard to remedies, "It may be remarked at the outset that there is no known method of exterminating these nematodes from the soil when once they have become established there, and consequently it becomes imperative to call attention to the necessity for dealing summarily with the pest in the earlier manifestations of this new disease. Thousands of experiments have been made on the Continent with a view to eradicating the *Heterodera* from the Beetroot fields, but without success. Applications of alkaline solutions and alkaline salts to the soil as manures have met with some success. Top-dressing in spring with muriate of potash or sulphate of potash has been found most beneficial. Lining in some instances and working in of salt have diminished the evil effects of the parasites, and the former should be tried, especially where the soil is full of humus from the indiscriminate use of large quantities of organic manures. As soon as an affected plant is seen in a garden it should be grubbed and burnt on the spot, and quicklime applied to the ground in the immediate neighbourhood. All implements used in cultivating infected gardens should be properly cleaned before being used among healthy crops, and the planting of 'sets' taken from infected gardens should be discontinued." It is difficult to determine the rate at which the parasites would spread if left to themselves; there is no doubt that the parasites are at present largely carried from "hill" to "hill" by the incessant cultivation which goes on in the Hop garden. Another new pest is a small beetle, *Helophorus rugosus*, to which Miss Ormerod has given the name of the Turnip mud beetle, which eats the leaves of Turnips, and its grubs feed on the upper part of the bulbs and in the leaf-stalks. They do most damage when the plants are small. Hitherto the attacks of this insect have only been noticed in Scotland, but owing to its small size and habits it is highly probable that this may have been overlooked in England. The beetles are only about a quarter of an inch long. The thorax and wing cases are deeply grooved, and are usually covered with soil and dirt, which it is difficult to free them from on account of the roughness of these parts. This adventitious covering renders them very difficult to find. The usual remedies for the Turnip flea beetle are recommended, or nitrate of soda sprinkled along the rows. One of the spring-tails (*Smynturus lutea*) is reported on for the first time. It was found injuring Turnip crops in Aberdeenshire. It feeds on the leaves, generally on the undersides. These spring-tails are very small, measuring only the thirty-second of an inch in length. They are of a yellow or orange colour. Three species of ground beetle—*Pterostichus madidus*, *Harpatus ruficornis* and *Calathus rutiloides*—are important as being destructive to ripe Strawberries. The ground beetles, of which there are a large number of species, are very active insects with sharp jaws, and are usually carnivorous, their structure and habits being well fitted for preying on other insects; it is, however, evident that they relish Strawberries. In market

\* "Notes of Observations of Injurious Insects and Common Farm Pests During the Year 1894, with Methods of Prevention and Remedy." By Miss E. A. Ormerod. Simpkin & Marshall.

gardens where a considerable acreage is under Strawberries it may be questionable whether it is good policy to destroy them or not; but in private gardens I should strongly advise that they should not be killed, as the amount of service they and their grubs do in destroying other insects is very great. Placing straw or lawn mowings under Strawberries is, I consider, a very questionable proceeding, as both harbour garden pests of various kinds. It is much better to employ some other means of keeping the fruit off the ground, such as the wire guards made for that purpose. The appendix of 42 pages gives, as the authoress says in a note at the commencement, "In a connected form such an abstract of the minor points of information regarding warble fly, contributed to me by British observers as would place all that is requisite regarding the history of the infestation, as it has been observed in this country, together with proved means of prevention and remedy, in a conveniently available form before those practically interested." This abstract has evidently been prepared with much care and trouble, as the amount of statistics given in various tables shows most conclusively. It should certainly be studied by all who are engaged in breeding cattle. G. S. S.

### THE HORTICULTURAL HANDBOOK AND EXHIBITORS' GUIDE.\*

This book was first published about twelve years ago under the title of "The Horticultural Exhibitors' Handbook," and the appearance of a new edition with a slightly altered title and revised by Mr. Dunn, of Dalkeith, may be taken as some evidence of its usefulness to the class for whom it has been compiled. The main body of the work remains the same as in the first edition, being separated into four divisions, dealing respectively with plants, cut flowers, fruit and vegetables. These divisions are divided into sections, that of plants, for example, being very comprehensive. Nearly all of both the flowering and fine-foliaged plants that appear at shows are alphabetically arranged, and concise, practical cultural instructions are given as to growth and training to secure exhibition specimens. Even those who never exhibit would find much here that could be read with profit, as the details of culture have the same practical value to all. In the supplement the Rose, Carnation, and Chrysanthemum have been revised, because of the considerable additions made to these three great families of flowers within the last decade. Some of the best Tea Roses, as Edith Gifford, are left out, and the selection nothing like so good as it should be. A classification of competitors is given also. This may be useful, but the disputes that arise are more from the loose way in which schedules are drawn up than from any difficulty of defining the difference between practical and amateur gardeners. The supplement concludes with a chapter explaining a new system of judging horticultural exhibits "by a simple and easy method which, while doing full justice to cultural merit as the leading object of award, aims at giving fair credit as to the relative value of the exhibits."

**German books on forestry.**—Dr. Schlich kindly sends us the following in reply to a question on the subject: If you want a compact book on forestry, the whole in one large volume, get "Lehrbuch der Forstwissenschaft," von Carl Fischlach, latest edition. I only have the third edition (1877), published by Julius Springer, Berlin. I presume he also brought out the later editions. A somewhat more modern work is "Encyklopädie und Methodologie der Forstwissenschaft," by Dr. R. Hess, published by C. H. Beck, Munich (three parts). If you wish to go into full details get the following: "Der Waldbau," by K. Gayer; Paul Parey, Berlin.

\* "The Horticultural Handbook and Exhibitors' Guide." By Mr. W. Williamson, Tarvit, Etc. Revised by Malcolm Dunn. (W. Blackwood and Sons, 1895.)

"Der Forstschutz," by Dr. R. Hess; Teubner, Leipsic. A translation of this is in the press and will be out shortly. "Die Forstbenutzung," by K. Gayer; Paul Parey, Berlin. "Die Holzmesskunde," by E. Bauer; Paul Parey, Berlin. "Die Waldwirthschaft," by Heyer, latest edition by Wimmerauer; Teubner, Leipsic. "Die Forsteinrichtung," by Judeish, Dresden, Schönfelds, Bushardt. The translation of Hess's "Forstschutz" is in type. The translation of Gayer's "Forst Utilisation" ought to come out before the end of the present year. Volume 3 of my "Manual of Forestry," containing forest mensuration, valuation and forest working plans, has just been published by Messrs. Bradbury, Agnew and Co.

## GARDEN FLORA.

### PLATE 1012.

#### THE COLLEGE GARDEN SLIPPER-WORT.

(WITH A COLOURED PLATE OF CALCEOLARIA BURBIDGEI.\*)

This is a hybrid, raised in the College Botanic Gardens, Dublin, from seeds cross-fertilised in the autumn of 1879. The parent plants were *C. deflexa* (*Botanical Magazine*, t. 6431), a species perhaps more generally known as *C. fuchsiae-folia* in gardens, and figured under that name in *THE GARDEN*, vol. xv., plate 258, where a full and accurate review of the species may be found. The male parent was the old *Calceolaria Pavoni*, named in honour of the traveller Pavon, and figured in the *Botanical Magazine*, t. 4525. *C. deflexa* is also a Peruvian plant, introduced in 1878, and, as its specific name implies, it is remarkable for its smooth and glossy, Fuchsia-like leaves. The only element of doubt as to the above parentage is that a plant or two of the well-known *C. amplexicaulis* (*Botanical Magazine*, t. 4300) was in bloom in an adjacent greenhouse, and it is just possible that some insect may have carried its pollen to the stigmas of *C. deflexa*, which I had only touched with pollen from *C. Pavoni*. Personally, I should have had no suspicion of this having taken place, all the evidence of the hybrid plant itself bearing in the contrary direction; but when Dr. John Macfarlane was making his series of microscopic studies of the minute structure of various hybrid plants at Edinburgh some years ago I sent him *C. Burbidgei*, together with both its parents, and he then thought that he detected signs of *C. amplexicaulis* in the hybrid. Be this as it may, the result is a free-growing plant of robust habit of growth, having hoary, opposite, perfoliate leaves, in this respect somewhat resembling *C. Pavoni*. It is hardier and more free-flowering than that species and blooms from November until March in a sunny greenhouse.

This hybrid plant was named by Mr. W. E. Gumbleton, of Belgrove, in *THE GARDEN*, vol. xix., 1881, at p. 59 of the number for January 15, the name employed being *C. hybrida Burbidgei*. At a later date Mr. Goldring found the plant flowering at Kew, and Mr. Cannell also gave it a trial at Swanley as a winter-blooming plant with some success. As a pot plant, however, I could never do much with it, but as a greenhouse pillar climber, planted out in a bed of loam, peat and sand, it grows 10 feet to 15 feet in height and blooms most profusely all the winter and spring months. Its habit is really semi-herbaceous, for although it never dies down and is always more or less evergreen,

\* Drawn for *THE GARDEN* in the Royal Gardens, Kew, by H. G. Moon, Nov. 17, 1894. Lithographed and printed by Guillaume Severelyns.

it sends up a new crop of shoots from the base every summer, and when these have attained a height of from 3 feet to 5 feet it is best to cut nearly all the old blooming growths away, so as to make room for the younger ones. As so treated my plant—one of the original seedlings—has occupied the same position in a cool greenhouse for fourteen years. In fact, to have it at its best it requires liberal root room, good open compost, and plenty of head room near the light for its great panicles of clear yellow flowers. The plant will not be found in "Index Kewensis," from which work garden hybrids are excluded, but it is mentioned in Nicholson's "Dictionary of Gardening," vol. i., p. 239, and notes of its having bloomed in various places occur in *THE GARDEN* and other horticultural papers from time to time. The plant is easily propagated from cuttings at any time during the spring and summer months, and it is, as indicated above, a rapid grower. In *THE GARDEN*, vol. xx., p. 422, Mr. T. Smith alludes to *C. Burbidgei* as improving on longer acquaintance, and also mentions that he effected the same cross, but whereas my own crop of seedlings was all exactly alike, with a strong bias towards *C. Pavoni*, his were different, producing "every form of foliage from a slight departure from the seed parent to that of the pollen parent almost pure and simple." It would be interesting to know if Mr. Smith's seedlings showed any marked differences when they flowered.

On glancing over the older volumes of the *Botanical Magazine*, *Botanical Register*, and other botanical and horticultural publications of half a century or so ago wherein many species of *Calceolaria*, at that time but recently imported, are illustrated, one regrets that the old species or wild varieties are so rarely seen in our greenhouses to-day. Many of the sub-shrubby kinds are nearly hardy, and some are most graceful in habit, while others have flowers most quaint in form and brilliant in colour. The dainty little *C. Fothergilli*, from the cold and wind-swept Falkland Isles, and *C. Kellyana*, one of the early garden hybrids, have grown and flowered here out of doors, and the pretty little annual *C. chelidonioides* is naturalised in many gardens. *C. rugosa*, yellow, and *C. violacea*, both shrubby kinds, are also hardy in mild localities, and well worth careful culture. The essential characters of form and colour of the College Garden (Dublin) Slipper-wort are beautifully shown in the accompanying illustration.

F. W. BURBIDGE.

## THE WEEK'S WORK.

### THE KITCHEN GARDEN.

**ROUTINE WORK.**—Where large breadths of early vegetables are grown there will now be plenty of work in the shape of thinning out the young seedlings, using the Dutch hoe between the growing crops. Upon no account allow such things as Carrots, early Turnip-rooted Beetroot, and Spinach to grow beyond the natural thinning size, or irreparable mischief will be done, as not only is general weakness thereby encouraged, but the work of pulling out the plants where thickly clustered together opens the surface to such a depth, that drought at the roots and its attendant evils are bound to follow, especially on hot sandy soils. In thinning Carrots proceed gently at the first, as the Carrot fly is almost certain to be very troublesome this season, especially in exposed gardens, owing to parching winds and a scarcity of atmospheric moisture. Immediately this pest

1907 - [illegible] - [illegible]

appears, dust with wood ashes pure and simple, do not mix lime with it, as this is apt to burn the tender growth, and the former ingredient is always effectual. When sparrows attack the young leaves of Beet, wood ashes will drive them away. The same piecemeal system should be adopted when thinning out the Beet, a second and final thinning being given in about a fortnight's time, should genial weather accompanied by showers set in. A keen watch must be kept, as slugs and snails are sure to be numerous, despite the severe winter. The early morning is the best time to search for the former, and the evening for the latter pests, when they can be quickly despatched by lime or salt. This should not be thrown on to them where they are, but be put into a flower-pot and the pests thrown into it, using a plant label for the purpose. Where the French Forcing or any other of the earliest section of Carrots is growing on raised beds in dry situations the crop will now be greatly benefited by occasional waterings, the morning being preferable for this operation until the nights get warmer, when afternoon watering will be best. I have sometimes given a shallow mulch of spent Mushroom manure to early Carrot beds with advantage.

**TURNIPS.**—Sowings at intervals of three weeks will now be necessary where this vegetable is held in esteem, as no root crop degenerates so rapidly after arriving at maturity as Turnips, although

The centres only of the spaces between the rows should be utilised, so that walking room is allowed for gathering the Peas. As an actual summer Radish no sort is equal to the red and white Turnip kinds, these being firm and less liable to eat hot or stringy. Although growing in shady places, Radishes after this date must be regularly soaked with water if tenderness and high flavour are important. Moreover, nothing responds more quickly to applications of manure water, but after using this, clear water should always be given to cleanse the tops.

**TRIPOLI ONIONS.**—The surplus bulbs of the Tripoli section which were transplanted as advised during March will now be established and growing fast. It is a capital plan to mulch between the rows with Mushroom manure, previously giving a good dressing of some quick acting and safe fertiliser. I find the Trebons a first-class Onion to sow in autumn, and one that stands the winter even better than the ordinary so-called winter Onion. I have a small bed of it, and every plant looks healthy and promises to swell out into normal sized bulbs. They do not grow away so quickly in the autumn, consequently they get less gross and sappy and stand severe frost much better. I believe some other varieties of spring Onion would do equally well if sown in September on firm ground not too heavily manured. In fact, too much manure is an evil with all autumn sown

The Sweet Bay (*Laurus nobilis*). See p. 301.

lifting and laying in under a north wall will in a measure check this. After this date the Early Milan should be replaced by the Snowball and Six Weeks type, these being of rapid growth and excellent flavour. To provide against failure, several sorts may be sown at each sowing. Dobbie's Model, a Turnip much resembling Snowball, is a grand variety. So also is the old Purple-top Munich. For those who are fond of a yellow-fleshed sort Veitch's Golden Ball is as good as any. A border which only receives the sun's rays for a portion of the day is to be preferred for Turnip sowing now. In such a position they come on gradually, do not flag at midday as do those on south borders, and the maggot is far less troublesome. Give a liberal but not over-rich harrow, sow thinly, and remove a percentage of refuse plants directly they can be handled and before they crowd each other. I strongly advise the use of guano for Turnips in preference to farmyard compost, this latter, particularly on strong land, inducing hollow bulbs and long tap roots. June sowings do well on north borders if well worked and exposed for several weeks to the action of the air. Wood ashes cannot be too freely used amongst Turnip crops, either when digging the plot or as broadcast sowings, to be hoed in immediately afterwards.

**RADISHES.**—From the present to the expiration of the outdoor season Radishes thrive much better if favoured with partial shade. Where room is abundant there is, of course, no necessity to sow between rows of Peas, but they do well in such a position and last a good time in eatable condition.

batches, assistance being easily given in spring from the surface. Spring-sown rows will now need the Dutch hoe between them, but thinning can hardly be commenced until the surface has been well moistened by genial rains, or the young seedlings will snap off, leaving the base of the bulb and root in the ground only to grow away again. Give a good coating of soot to ward off the Onion maggot, always taking the precaution to use it after having been exposed to the air for some time. If sown over the crop soon after being taken from chimneys it is apt to do more harm than good.

**STAKING PEAS.**—This will now be necessary with many early rows. There is, however, a great deal more in staking Peas than many appear to be aware of. No greater mistake can possibly be made than to ram in a great number of thick stakes on either side of the rows, thereby darkening the space between and weakening and retarding growth. Far better is it to employ a moderate number of main sticks, filling in the intervening spaces with smaller spray-like material. This will admit a maximum amount of sun heat and light, and if the haulm should eventually fall through here and there, it may be brought back and kept in its place by running tar twine or coarse string the whole length of the rows, entwining them round the main stakes at intervals. In regard to earthing up, much more is done of this than is needed. For the earliest crops the less earth drawn up to the Peas the better, as it shuts out the sun's warmth and often throws off rain which would otherwise descend to the roots.

There is little fear of injury from drought at the roots till the July crops commence to pot, and even then I would advise moderate earthing only, giving a good mulch of short litter on each side of the rows to conserve the moisture. As each sowing comes through the surface, protection must at once be given, as not only are sparrows more numerous than usual, but natural food more scarce also.

**FILLING UP BLANKS.**—After a somewhat indifferent harvest in 1894, many of the larger-seeded marrow Peas are not germinating so well as could be wished. Moreover, snow-storms were very prevalent just after many sowings of this section had been completed; consequently much of the seed has rotted. Under such circumstances, the best, and indeed only, plan is to sow at once either in boxes or pots, removing to a comfortable greenhouse, or similar place, until growth is a couple of inches high. Hardening off may then be quickly accomplished and the vacancies all made up. The same may be said of Broad Beans, these being very liable to rot in late spring and in unfavourable soils. It will be as well after planting to protect these heat-raised portions of the rows by small sprays of Yew or Laurel.

**PRICKING OUT AND HARDENING OFF.** Whatever press of other work there may be, the all-important operation of pricking off all crops now in the rough leaf must not be neglected. Crops of Celery will, in the majority of places, be fit for this ordeal, and as soon as this is completed the boxes, if such are used, should be at once removed to frames, and after being duly sprinkled and kept close for a few days exposed to plenty of pure air to stiffen and consolidate growth. Where Celery is expected in September early sowings will by this time be so far advanced as to warrant removal from cool frames or pits to sheltered corners in the open air, some means being adopted for providing a slight screen from sharp frosts, should such occur. The earliest Brussels Sprouts may now be treated in exactly the same way to prepare them for transplanting to the permanent quarters the second week in May. A little artificial manure may well be given now, as if the weather is unfavourable and planting postponed, the plants are apt to suffer from want of nourishment. Cold water from wells should not be used, rather using that which has been exposed to the action of the sun for a time. J. CRAWFORD.

#### FRUIT HOUSES.

**EARLIEST GRAPES.—POT VINES.**—The very early supplies are mostly obtained from pot Vines, and to have good colour and the best flavour a lower temperature with less atmospheric moisture must be maintained. If the plants for next year's forcing are not in their fruiting pots no time should be lost in potting them, as the ripening season is never too long, for the wood of pot Vines to be forced early should be as hard as possible. Pot firmly, burying a portion of the shoot. By this means the plants root out freely at the base and shorter jointed wood is secured. The compost should consist of good loam, some artificial manure, wood ashes, or mortar rubble. If room is required for the young plants, to save time I have carefully transferred a few pot plants to a cooler house, taking care to give enough water, as the roots dry quickly after being plunged. A few growers cut back their old canes early in the autumn and force again, but I do not advise it when young canes can be grown, as though the old canes force more readily, they bear smaller bunches. If it is desired to force again, re-pot into pots two or three sizes larger, growing on for a few weeks in a warm moist house, letting the lateral growth run freely. In potting it is well to remove drainage and strong roots, and when the pots are full of new roots the plants should be hardened off, removed to a sunny wail, carefully watered and pruned early, leaving a couple of the best buds or eyes at the base of this season's wood.

**PERMANENT VINES.**—The fruit now colouring will need more air and less atmospheric moisture, but

it is well not to cease damping down even when the Grapes are colouring, as the Vines will soon get red spider unless a genial atmosphere is maintained. Leave air on the ventilators at night and increase the amount during the day, with a nice warmth in the pipes in cloudy or damp weather. Grapes finally swelling should be thoroughly watered at this stage, giving food now, as later it cannot be applied. A dressing of guano or liquid manure may be given before watering. The berries if at all thick may receive a final thinning. The growth of early Vines will now be less vigorous, and the laterals should be regulated freely over all parts of the trellis, pinching back the strong ones, but allowing the leaders or others required for extension to ramble freely at the back of the house. This will promote root growth and greatly assist in swelling up the buds at the base required for next season's fruiting. Now is a good time to give the inside borders a good surface dressing with manures. For light sandy soils cow manure is excellent, and if a little dried it does not run so close together. I have used it and short stable manure in equal quantities with advantage. The male not only feeds the surface roots, but saves the water-pot, and also prevents the spread of insect pests by retaining moisture.

**SUCCESSION HOUSES.**—These will now be at a critical stage. Thinning will be the most pressing work, and with Vines in full growth it is well to thin early, even if a second thinning is necessary afterwards. In earlier notes on thinning I have not advised such rigorous cutting away of bunches as is now necessary, as there is now little fear of bad setting in carefully-ventilated houses. Muscats require more careful management, as the least drought often affects the setting, and in some old houses with little sunshine and much rain it is well to assist by fertilising with Hamburg pollen, to maintain a high temperature, with a free circulation of air all over the house, and in bright weather to damp down during the day. The temperature for Muscats at the stage named may be 70° at night in mild weather, allowing 70° during cold or windy weather, with a free rise during the day up to 95° at closing time. Houses recently started for late Muscats need liberal treatment. There should be no retarding after this date, as much better results will follow high culture, and such Grapes will keep better. Syringing overhead must cease as soon as the Vines show the bunches freely, and it is well to disbud early and remove superfluous bunches. Muscats always show a profusion of bunches, so that a good proportion may safely be removed, and even then they will need another thinning after the flowering period is safely past. Vines in outside borders are slow in making new roots until the growth is advanced, so that the plants have not required water. It is well to give a dressing of a good fertiliser, and wash it in, doing the work when the sun warms the soil. Should the soil be dry a watering now will tide the Vines over the flowering. Inside borders should likewise have a good soaking when the bunches are showing freely, but food will not be necessary till the fruit is set. The temperature advised for earlier houses will apply to later Vines, 70° at night, with a rise of 10° to 15° by day, avoiding a damp atmosphere at night when at the critical stages.

**LATE VINES,** such as Lady Downe's, Gros Colman, and others, will likewise need encouragement and pushing on, as with favourable weather there is none too much time to perfect a good crop, and for keeping, the fruit should be thoroughly matured before the days get short and the nights cold and damp. Hamburgs require less time than the late kinds named above, but it is not wise to retard even Hamburgs. Now is a good time to add to outside borders if the late varieties are in need of more room and are planted outside, as by the time the roots are active the soil will be warmed and in nice condition. Inside borders of late houses need similar attention, and it is well to do the work by the end of April or early in May.

**PLANTING.**—Planting Vines in outside borders is best done at this season. These may be much

assisted by covering the surface over with warm litter for a few weeks after planting should cold sunless weather follow. This will allow of more liberal treatment in the house, as the Vines will form roots sooner and take hold of the new soil. Any late planting of houses which are not doing well may yet be done. For this work Vines struck from eyes this season or from last season's canes may be used. I have used both and got equally good results. Should the last year's canes be selected, these will have been under a north wall in the open for a time, and if not cut back this should be done. To prevent bleeding it is well to lay the canes down on their sides, keeping dry for a short time. They may be cut back to within a few inches of the base and then allowed to break slowly, planting in inside borders when a few inches long or just as the new roots are starting. If newly-struck Vines are used they may be planted at any time when ready, but should there be any delay or the house not be available, the Vines may be planted in boxes or any other mode adopted to allow the roots to run freely.

**FORCED STRAWBERRIES.**—From this date the pot plants will suffer badly if on exposed shelves against a wall, and will require so much watering, that the plants are most difficult to keep free of red spider, no matter how well attended to in the way of food and moisture. Many growers advise saucers or other means to retain moisture, but I do not advise this, the flavour of the fruit being so much impaired. I do not think any system can equal cold frames for plants well advanced and required for late fruiting. The plants, stood on a cool coal ash bottom, require less water, and the fruits are equal to those from out-door plants. Wherever a cold house or frame can be spared for the latest lot there is a great saving of time with watering. Plants in vineries or Peach houses should be cleared away at the earliest moment possible. Plants just setting their fruits in warm pits do well plunged half-way in leaves or fibre if the drainage be good. Grown in this way, it is advisable to stake each truss and to air freely if the pits are low and moist, using fire-heat till the fruits are set and thinning early. Such varieties as President, Sir J. Paxton, Sir C. Napier, and British Queen are noted for their good crops and quality if forced slowly to provide the late supplies. The first three require severe thinning to get large fruits and plenty of food when swelling the crop. British Queen will do well with more warmth during the setting and should be kept free of mildew, as this variety and President are soon much crippled if the pest is allowed to spread. To check mildew syringe all parts of the plants freely with sulphur and water, and dust the soil or shelves with dry sulphur when the house is dry, keeping the plants dry overhead for a few days after applying the sulphur. When introducing plants into warm houses at this date it is well to dress with sulphur before giving much warmth, as once mildew appears it soon spreads to other plants. A little attention should now be paid to the runners planted last July or August for the supply of forced material this season. The flower trusses must be removed as they show, and in dry weather the plants well repay copious supplies of liquid manure or water. If the latter, give a surface dressing of guano before watering, and in poor or light soils mulch with manure between the rows. This will encourage the plants to form very early runners for layering. As a mulch, spent Mushroom or old Cucumber beds answer well.

G. WYTHES.

**The golden flowering Currant** (*Ribes aureum*)—Although this shrub has a rival now in bloom (also with yellow flowers) in the shape of *Forsythia suspensa*, whose attractions, this season especially, are so brilliant as to put it somewhat in the shade when both are seen at a distance, it is, I think, at close quarters a shrub of almost equal charm. Its neat foliage is at this early stage of a singularly pleasing tender shade of green, and intermingles most effectively with the short crowded flower-spikes. This species is one (like *R. sanguineum*)

whose flowers vary a good deal in size and colour. In the better varieties the flower individually is close on half an inch in diameter, with five oval petals. The colour is always yellow, but ranges from a rather pale shade to golden or orange. The variety *aurantiacum* is perhaps the best, having not only richly-coloured large flowers, but it is also of a sturdier habit than is common to the species as a whole. The leaves, quite smooth and free from hairs and consisting of three lobes, measure each from 1 inch to 1½ inches across. The flower-spikes are slightly drooping and 2 inches to 3 inches long. The shrub does not often attain a greater height than 6 feet or 8 feet. Like the other flowering Currants, it can be easily and rapidly increased by cuttings. It was introduced from North-western America in 1812.—B.

## KITCHEN GARDEN.

### TOMATOES IN THE OPEN.

WHEN we have such a summer as that of 1893 there is no difficulty in growing heavy crops of well-ripened Tomatoes. Not only did the plants growing against sunny walls and fences produce grand crops, but those quite in the open succeeded nearly as well. Even self-sown plants left to take their chance gave a considerable weight of fruit, much of which ripened. We neither expect nor desire many such hot dry summers, but if we only get a little more sunshine than we had last year, or say a good average season, then there is every likelihood of Tomatoes more than repaying for what little trouble is expended on them. If it should happen that more ripe fruit is forthcoming than is wanted for immediate use, any good house-keeper or cook ought to know how to store or otherwise utilise these, while the unripe fruit can be made into fairly good preserve and is excellent in a pickled state.

Too often Tomatoes are raised a month or six weeks earlier than they ought to be. Kept standing about in a badly root-bound state, the plants are sure to become leggy, the stems also hardening. Those raised later, the seed being sown, say, early in April, can be grown rapidly to a serviceable size in a temperature a little higher than is needed by ordinary greenhouse plants, and not being badly root-bound, they take more quickly to the soil in which they are finally planted. Late raised plants may be planted out of 4-inch pots, while those raised earlier have to be shifted into the 6-inch size, and even then become badly root-bound. One of the consequences of this turning out root-bound plants is the inevitable loss of their first bunch of bloom, the younger ones behaving better in this respect, and being usually the first to give ripe fruit. Soil that will grow Potatoes profitably will be quite as well suited to Tomatoes. When, however, that found at the foot of hot dry walls and fences is of a poor nature, and probably hard and dry, remove it to a width of 15 inches and 1 foot deep, replacing with fresh loam with a little manure added, or, failing the loam, the best garden soil available. In some instances, all that is needed is a little fresh soil and rotten manure mixed with the old soil. Good crops of Tomatoes are sometimes had without the addition of either fresh soil or manure. If in a dry state, break it up and give a thorough soaking of water or liquid manure the day previous to planting. The plants should be well hardened off and planted out during the first week in June. If plentiful, arrange them 12 inches apart and keep them to

a single stem; if scarce, dispose them 3 feet apart and lay in two side shoots so as to have three main growths 1 foot apart. Should head room be limited, train obliquely, otherwise take them straight up the wall or fence, not stopping the leaders till four or five bunches of fruit are formed or showing. From first to last not a superfluous side shoot should be allowed to develop. If left till they need a knife to remove them they will have weakened the plants to no purpose; therefore, pinch them out as fast as they show at the base of the plants and at the axils of the leaves. Leave the primary leaves intact till such time as ripening of fruit commences, when they may be shortened to about half their original size so as to admit of all the sunshine possible reaching the clusters. If the soil was made very firm about the roots, there is little likelihood of the growth being unduly soft and shy-bearing, and, as a rule, it pays well to mulch with short manure and also to water occasionally till the plants are fairly well established, and subsequently during very dry, hot weather.

Those who have neither garden walls nor fences may yet be successful in growing Tomatoes without these aids. I once grew extra heavy crops on plants trained up the front brick wall and on to the roof of a low forcing house, a temporary raised border being provided for the roots. Wooden screens fixed in a sunny position are sometimes utilised for Tomato culture, while thousands of plants are annually grown, with varying success, quite in the open. These may be dotted thinly among early Potatoes or planted in close succession to any lifted extra early. In the former case the Tomatoes might be planted 12 inches to 15 inches apart in every second furrow between the Potatoes, and they may be arranged on clear ground the same distance apart in rows running from north to south and from 3 feet to 4 feet apart, or be put out about 30 inches apart each way. Each isolated plant should have a strong 4-foot stake placed early against it and be kept well secured to this, topping it when near the top of the stake and closely removing all side shoots. The plants sometimes produce exceptionally heavy crops under such conditions. A ROVER.

**Drumhead Lettuce.**—I was very pleased to read the practical notes by Mr. Wytles (p. 233) on summer Lettuces. I quite agree with him as to the value of the Drumhead Lettuce. I have found it a most reliable Lettuce in Scotland for summer culture, being equally good in heavy and light soils. To produce first-class Lettuces on poor or sandy soils that dry quickly in the height of summer, I would recommend manuring and digging in late autumn or early winter, re-manuring and digging in spring. In this way the old and decayed manure turns up and is mixed with the surface soil, giving the young seedlings a quick start.—J. CRAIGIE, *Auchentoshan Gardens, Dalmeir.*

**A good summer Cauliflower.**—For sowing at this date or earlier, few varieties are superior to Veitch's Pearl, a remarkably fine main-crop variety. This variety is far superior to the Early London, nearly as large, but with a pure white curd of extremely delicate flavour. For summer use it may always be relied upon. For some years I have grown it between the rows of tall Peas, and it has never failed even in dry seasons: the heads being well covered by foliage do not open so quickly as those of Early London. If sown in March and again at this date there will be a succession of good heads all through the summer months till the autumn Cauliflowers come in. I do not advise growing it for early spring planting.—G. W.

**Frame Marrows.**—If the plants can be given a little warmth at the root and shelter overhead by frames for a few weeks there is a great saving of time and fruit can be had very early. Frame

Vegetable Marrows are a paying crop if planted under glass at the end of April and given shelter for about six weeks. I am aware many plant in frames in which early Potatoes have been raised, but there is no warmth at the roots, indeed, the reverse, the soil in some cases being impoverished and in a wet state. By re-making the bed—that is, adding new heating material—there is much time saved and the plants will furnish much better crops for a longer period. Those at all short of manure may with advantage pot on their plants and thus get strong material for planting. For this purpose, plants, if raised singly in  $\frac{1}{2}$ -inch pots and then given a shift into 9-inch ones, will show fruit freely when planted out. I do not like sowing too early, as if the plants get stunted they are a long time in making a start when planted out. It is a good plan to plant out of the seed pot if one can give the room. If only one plant is allowed to grow in a 5-inch pot, two or more seeds may be sown, thinning to the strongest, as only a little warmth is needed for a short time. It is an easy matter to dig out a small square of the old bed, refilling with new heating material, and planting in a few days. The earliest frame Marrows I have grown are Long White and Pen-y-byd. The Long White, though a large grower, is one of the earliest if the shoots are kept stopped. Pen-y-byd is a dwarfer grower and a splendid frame Marrow, sets freely under glass, matures rapidly, and when cooked is of delicious flavour. I have grown this variety in a pot and it did better than any others with restricted root space.—B. M.

**Lettuce Golden Queen.**—Rarely has there been such a scarcity of Lettuce as there is at the present time. In my case not a single plant is left from the autumn sowing, though protected by frames and grown in great quantities. Fearing what would follow the severe frost after a mild winter, I sowed Golden Queen in February in boxes and planted it out at the middle of March in frames with a little warmth. At this date (the third week in April) the plants are just turning in. This is the quickest growing Lettuce I have tried, and though small will be invaluable during the next few weeks. Golden Queen forms nice small hearts, somewhat after the Tom Thumb variety, the leaves being of a golden or very light green colour. Being a small grower, it occupies little space and is well worth frame culture. It is of a particularly delicate flavour.—S. H. B.

**Black Currant Rhubarb.**—Is it generally known that there is a variety of Rhubarb the stalk of which resembles in point of colour the juice of the Black Currant, and can anyone give the name of the variety? When going through the kitchen gardens connected with Chilton House, the Somerset residence of Mr. A. J. Goodford, I noticed several large clumps of a distinct and, to me, quite unknown variety of Rhubarb. In my estimation it fully merits the prominent position assigned it in an old-fashioned and attractive garden owing to its ornamental appearance. The variety would appear to be as early as the common early red forms, but the stalks are scarcely so stout and the leaves more acuminate. It is the colour that attracts. The rich dark crimson stalk seems to carry a heavy bloom, and this adds to the beauty of the stalks. Not only does this Rhubarb resemble the Black Currant in point of colour, but the flavour is also said to be not unlike that of the latter. It is greatly esteemed for making jam, and with the colour and flavour of Black Currant added the advance on the ordinary Rhubarb for a similar purpose ought to be unmistakable. The clumps alluded to have occupied their present position for many years past, the original roots having been received as a present by Mrs. Goodford. More than that I am unable to state, not caring to make further inquiries till I know for certain whether the variety is known to any of the readers of THE GARDEN.—W. I.

**Cabbage Early Rainham.**—This is by no means a new variety, but one that is very hard to beat for earliness, quality, and freedom from bolt-

ing. It has a remarkably good constitution, this being evidenced in several places hereabouts this spring, the plants looking strong and already commencing to heart in. In the neighbourhood of Rainham and Barking, Essex, this Cabbage is grown in large quantities for market, and I have an idea that Ellam's Dwarf is nothing more nor less than a selection of the above variety. Its table quality is of the finest.—J. C.

**Carrot Veitch's Matchless.**—For present sowing this recent introduction is superior to any variety I have grown. For some years I sowed James's Intermediate for main crop, and though excellent in many ways it is not nearly so heavy a cropper as Matchless, the newer variety being firmer, keeping better, more vigorous and doing well in soils where other sorts fail. I have grown it for three years as a main crop variety. In the dry season of 1893, in a thin, gravelly soil Matchless turned out well, other Carrots cracking badly when lifted in the autumn after rain.—S. H. B.

## ORCHARD AND FRUIT GARDEN.

### THE APPLE BLOSSOM.

THOUGH most other fruit trees are very scant of bloom, the Apples have never looked more promising. This is not only the case with old standards in orchards, but most of the young trees are also well furnished with fruit buds. The other evening I was walking through an orchard which was planted about ten years ago. The person to whom it belongs takes a great delight in his fruit trees, and though by no means a professional, is one of the few in this district who get anything like an adequate return for their labours. Last year, which was by no means a plentiful one for Apples, there was a goodly sprinkling on some of the trees. Now those who are strong advocates for close pruning would do well to visit an orchard like this; it would go a long way to convince them that though pruning is an art, those who practise it the least secure the best crops of fruit. I also visited another orchard the trees in which had been pruned in the orthodox manner, and scarcely a bloom bud was visible on some of them, so closely had the shoots been cut in. Now one would think that a lesson might be learned in this manner even by those who consider themselves professionals. Most of the Apple trees in the former orchard were grafted by the person who owns it, he having selected the Crab stock, and it is curious to note the difference in their growth, some doing remarkably well, while others refuse to grow altogether. Trees of Ecklinville which have grown to a good size produce fine crops of fruit most seasons; the wood is clean and free from any specks, with not the least sign of canker in the trees. The same may be said of Lane's Prince Albert growing close by. From these the ground slopes rapidly to the east, and on the lower side where the soil is much more retentive these varieties canker badly. Cox's Orange Pippin also does well on the upper portion of the orchard, and the same may be said of several others, such, for instance, as Pott's Seedling, The Queen, Cox's Pomona, Wormsley Pippin, Loddington, Tower of Glamis, Yorkshire Greening, and several others. The varieties that do badly are Stirling Castle, Peasgood's Nonsuch, Ribston Pippin, New Hawthornden, Cellini, Lord Suffield, Warner's King, Wellington, and some of the more tender dessert kinds. From this it would seem that when planting Apple trees even in the same orchard the more tender kinds should have the best situations. If more attention were paid to this, the robust and hardy sorts would in

one measure shelter the others. There is often a vast difference in the soil of a small piece of ground, especially in hilly districts where it slopes rapidly, for while the upper portion will in all probability be well drained, naturally that at the bottom may be quite wet, and therefore unfit for the growth of some kinds. In such places it is not only drains that are needed, but rubble of some kind should be put under each tree to keep the soil sweet.

It is too soon to form any idea of what our Apple crop may be, but from all appearance the fruit orchards will present a beautiful sight in a few weeks' time. Some of the more hardy kinds would doubtless make pleasant features if planted alongside the woodland walks where the land is suitable. Their flowers in spring, like those of the wild Cherry, Crab, and some others, would be most attractive. The Old Hawthornden and King of the Pippins would be two good varieties for this purpose, the rosy buds of the latter being very attractive.

Busted Park, Uckfield.

H. C. P.

**Freely-grown fruit trees.**—Journeying through the home counties recently, I noticed a tendency to allow a more natural freedom of growth to fruit trees. This is a healthy sign, but injury is likely to accrue from a crowded growth. This is more likely to occur with trees which have been hard pruned for years and now within the last year or so allowed to extend. By thinning out the growths so that direct light can have free access to every part of the tree, the fruit will be finer and the foundation laid for a generally fruitful habit. In any case where the growth is crowded surplus shoots could now be cut away. If this is done carefully there need be little or no fear of damaging the buds.—Y. A. H.

**Peach Amsden June.**—It may interest some of those who have been bothered with the uncertain character generally of most of the American Peaches to learn that Amsden June can be depended on. For some years past I have grown Amsden June on the open wall, where it does capitally, ripening at the end of July. Acting on the advice of Mr. Wythes, of Syon House, with whom it does well, I last year planted a tree of this variety in a span-roofed house, and although the tree cannot yet be said to be established it is bearing a nice lot of fruit, which is well advanced and has every appearance of going on to maturity. The fruit is of good size and splendid colour, the flavour also being good. I grow Waterloo and have grown Alexander, but neither of them is so early as Amsden June. Those who want extra early Peaches should give Amsden June a trial.—J. C.

**Blister on Peach trees.**—I think it has, as stated by "W. G. C." (p. 276) been proved that what is known as "blister," which appears upon the foliage of Peach trees, is of fungoid origin, such attacks being aggravated by the cold winds and low temperature of early spring. These conditions appear to be necessary for the fungus spores to develop. Its hereditary tendency is also, I think, proved, and in many gardens the source of blister has been traced to a single tree, perhaps purchased from a nursery where this blister fungus was prevalent. As evidence of this I will give a case in point, and which was vouched for to me as a fact by a well-known gardener and fruit grower. In the garden which he had charge of, trees purchased from a nursery where the fungus was known to be, perpetuated the evil as each season for its occurrence came round, but it was entirely destroyed when clean trees were procured from another source and the older trees cleared out and burned. In this garden blister is comparatively unknown: at least, during the past nine years I may have pulled off two dozen leaves, but, strange as it may appear, these affected leaves appear about the same part of the wall annually in the direct line of cutting winds, and which

the protecting cover does not quite reach. I have never tried any fungicide for blister, as this has never been needed, but if this is a sure cure, blister should be stamped out of every garden where it is tried and used. I have never seen blister in unheated houses or under wall eases, which gives me the impression that with clean trees to start with and effectual covering afterwards, blister should not prove troublesome. Trees which are crippled in the earlier stages of growth, whether through blister or insects, however clean and free the growth may be afterwards, will never produce satisfactory crops of fruit.—A Young, *Abberly Hall*.

#### APPLE KING OF THE PIPPINS.

No dessert Apple is better known than the above, and it is more widely cultivated than any other sort that I know of. In some parts of England and also in portions of Scotland and Wales it is best known as Prince's Pippin, but under whatever name it is grown it is very popular, the tree being very prolific on almost all soils, very hardy, and under good management the flavour of the fruit is excellent. In some of the most suitable parts of the country for hardy fruit culture the quality of King of the Pippins is all that can be desired and only second to Cox's Orange and Ribston Pippins, but it is infinitely superior to both

*Apple King of the Pippins.*

in productiveness and healthy, vigorous growth. In some of the western counties, especially Herefordshire, the variety has been extensively planted for many years, the majority of large and small gardens, also orchards, having a few trees therein which rarely fail to crop well, or if they do fail, it arises from exhaustion following a very heavy load of fruit. When trees of King of the Pippins are supplied with copious quantities of liquid or solid manure the season must be a bad one indeed if no fruit is forthcoming; in fact, I have yet to see such trees fail entirely, which is more than I could state of any other variety. This being a fact, it is marvellous that planters, both for home consumption and for market, do not plant more of such a sterling variety. It may perhaps be stated by market growers that there are more profitable varieties of Apples than King of the Pippins. While admitting that there are cooking varieties that are more remunerative, I must confess to not having yet grown any dessert Apple that will pay so well over a series of years. Taking the past ten years' prices, I find the average comes out at a little over 14s. per cwt., and as many bush trees under skilled management on good soils will easily produce from  $\frac{1}{4}$  cwt. to  $\frac{1}{2}$  cwt. of fruit per tree, it may soon

be calculated what the returns should be in fruitful seasons from an acre of land. There are so many absolutely worthless varieties of Apples, that both large and small growers should set their face against planting any sorts but those that are known to be really good all-round varieties, such as the one now named. Another advantage possessed by King of the Pippins is its popularity in all markets, as nicely-coloured and properly graded fruit will command equally satisfactory prices in the northern or southern markets. In this respect it differs from Cox's Orange Pippin, which is practically of no value in the north and realises a very high figure in London.

As many trees of King of the Pippins will now be in bloom, or setting their fruit, I would suggest liberal treatment at the roots to assist to the utmost the efforts to produce a crop. Natural manures are excellent, as they are a complete plant food and supply all the elements necessary to plant life; but, unfortunately, many gardeners and others cannot obtain sufficient of this fertiliser, and are obliged to rely on so-called artificial manures, when there can be no question as to their great usefulness and feeding power if judiciously applied. By applying now 2 cwt. of muriate of potash and 3 cwt. of superphosphate, well mixed together, to each acre of

land devoted to Apple trees, the trees will be much invigorated, and of course the fruit will derive benefit as well not only in size, but later on in colour. Our soil is moderately light, and since using the above manures the Apples of all varieties have shown a marked improvement; but I think none have shown it in so great a degree as King of the Pippins, the colour especially being fine and the flavour rich and juicy, making it valuable for all purposes about Christmas.

W. G. C.

#### Strawberry Gunton Park.—I

have this season forced this new Strawberry, and consider it a valuable acquisition. Growing about one hundred plants, the runners having been secured from maiden plants early in the season, I was enabled to form a better idea as to cropping qualities than from plants purchased late and which may have borne a crop. The fruit of this variety is of a brisk, pleasant flavour and fine colour, and when well grown comes of a large size; indeed I consider it one of the most handsome Strawberries grown. It forces well and sets so freely that it requires severe thinning. The flesh is firm and the fruits may be sent a long distance, arriving in fine condition. The plants resemble La Grosse Sucrée in cropping, and the fruits swell so evenly, that there are very few small ones. I intend this season to secure all the runners possible and to grow Gunton Park largely.—G. W.

**Planting Figs in the open.**—Many have ceased to grow Figs on walls on account of their failing to crop freely. Barren trees could be made fruitful if more attention were paid to thinning the shoots in the growing season and keeping the roots under control. In planting young trees the roots should be carefully spread out, and as pot trees are the best for planting, select those with leaders. Plant in good loam, with a liberal portion of old mortar rubble, wood ashes, or burnt garden refuse. To promote a fruitful growth restrict the border by only allowing a certain space, and to do this, tiles, bricks or slates may be employed. Plant firmly and water freely as growth increases, giving a mulch of spent manure at midsummer. Figs could be grown on many

walls if the trees were looked after in the way of laying in new wood yearly, not shortening the leading branches. The fruit being produced at the end of the shoots, these if cut back only produce wood. It is a good plan in the late summer to shorten back a certain number of shoots by pinching and to leave sufficient leaders to extend the trees. These at this season may be laid in, merely removing barren growths.—G. W.

**Grape Bowood Muscat.**—I read some time ago (I think from the pen of the veteran Mr. Douglas) remarks on Bowood Muscat, and whatever may be said to the contrary I believe the variety so named is distinct from the Muscat of Alexandria. I was an underling in Wiltshire when that Muscat was brought to notice and sent out by the late Mr. Spencer. I saw in one house over two thousand growing, and was told they were all practically sold. Many experienced growers admitted that it was distinct, some giving it other names, but I know that many cultivators did not see the distinction, and classed it with M. of Alexandria. I know some nursery friends who have sold the Vines under different names, but believed they were alike. I have grown it (Bowood Muscat) when the stiff habit of bunch, free setting, and hardier constitution were very pronounced, and were easily noticed among the M. of Alexandria by the most casual observer. I planted two Vines of it here, but probably they were propagated from the same Vines which supplied the M. of Alexandria. A short time ago I visited a Forfarshire garden where a Vine under the name of Bowood Muscat appears to be remarkably distinct, and the intelligent gardener in charge said that every year the habit of Bowood Muscat was dissimilar to that of the M. of Alexandria in the same house. Mr. Murray, gardener at Parkhall (who is one of the most extensive Grape growers in Scotland), holds that there are distinctive habits in the two Vines, but I fear that this is a matter which now cannot be cleared up. The Cannon Hall Muscat, though not equal to the Muscat of Alexandria for flavour, is much larger in berry, and when grown, as by Mr. Kay at Finchley, worth going many miles to see.—M. TEMPLE, *Caron, Stirlingshire.*

**Liquid manure for fruit trees.**—The advice given by "E.M." (page 276) concerning the application of liquid manure to the roots of established Apple trees is worthy of notice. Many people who have orchards might get double the quantity of fruit and of an infinitely better quality by pouring the liquid from the farmyard around their Apple trees instead of letting it go to waste. House sewage is most valuable for the purpose, but where the orchard is grass-covered it should be diluted considerably, or it will kill the grass. In an orchard a few miles from here, where the trees were very old and showing signs of exhaustion, house sewage was applied during the winter, with the result that fine healthy growth and abundance of large fruit were produced the next season. Farmers in particular who have plenty of horse and cow urine might preserve their orchard trees in a fruitful and profitable condition by its judicious annual use, and that, too, without a great deal of labour. All orchards are further improved by being surface-turnd previous to the liquid being applied. This admits air and warmth the following spring, and induces the roots to come to the surface. I have no doubt that all kinds of hardy fruit trees would be equally benefited by the same treatment, also Vines. If, however, the border in which the latter are growing is composed of strong loam or is at a low elevation, injury might ensue from the winter use of liquid manure.—J. CRAWFORD.

**Strawberries forced in boxes.**—For some years, when I lived where timber was readily procured on the estate, I made it answer well in the case of Strawberries for the May and early June supply, and never had better fruit and with less labour. The boxes were made during the winter, the material being rough Larch wood cut by machine into strips 6 inches wide and an inch thick. The boxes were 6 inches deep when made, and six plants were placed in each

box, the length being 2 feet 6 inches by 12 inches wide. Narrower boxes, with only one row of plants, would be advisable for narrow shelves, but I grew the plants on stages in pits and the size named just filled the standing space, and the boxes, if not required for Strawberries, were useful for other things. By growing plants in this way there is not the continual drying as when in pots and the fruits are of excellent flavour. I do not advise this mode of culture for early forcing, but for the season named, and if the boxes can be placed end to end close to the glass in frames with space between the sides, a lot of fruit may be grown in a small space. It is necessary to stake the trusses of fruit, to thin early, and feed liberally. The boxes require very little drainage, and during growth, after being planted, should be stood on a rack or strips of wood to allow of moisture draining away freely. For boxing I never used pot plants, but layered the runners into square pieces of turf, the latter being let into the soil or bed with a trowel when layering. These runners did well when placed in the boxes, and the boxing was much sooner finished than potting. I grew other plants, such as French Beans, Potatoes and Peas, but with the first-named used narrower boxes and one row of plants.—G. W.

#### NOTES ON VINE CULTURE.

GARDENERS are very busy at this time of the year in the vineries, and it depends much upon the treatment the Vines receive as to whether they will produce handsome bunches and large berries with good bloom upon them. All the houses require attention, and as I write these lines there is a keen east wind blowing, but at mid-day the sun has power enough to raise the temperature to a high point. Air of course has to be admitted, but it ought only to come in from the opening at the top of the house: it is better that the sidelights should remain closed. In one of our houses the Grapes are being thinned, and at such a time the berries may become rusty—as gardeners term the discoloration and contraction of the skin. "How is it caused?" I am asked. I believe by careless handling of the berries, touching them with the hair of the head when thinning, or opening the front and top ventilators at the same time. This is sometimes done to make it pleasant for the person thinning during hot sunshine, but the cold east wind at such a time will do its work of injury. Thinning should if possible be done in the cool hours of the morning, and the smallest opening at the top of the house will admit sufficient air to make the atmosphere and temperature agreeable. In the second house the shoots ought now to be tied out, and stopping the growths should be frequently followed up. This is an important part of the culture of the Vine in the early stages of its growth. When growths are not wanted they should be stopped when they are 1 inch or 2 inches in length. All the stoppings from a good-sized vinery may be compressed into two or three handfuls if the work is done in good time. Some growers allow the laterals to run into shoots a yard or more in length before they are cut off. This cannot fail to be injurious to the Vines, by checking to a serious extent their growth. Stopping should be persistently followed up until the Vines have reached the flowering stage, when it is best not to interfere with them until the setting period is over. It does not matter much as to the treatment of the Black Hamburg or other free-setting varieties, but the Muscats and other shy-setting kinds may receive some sort of check which might have an injurious effect upon the setting of the blossoms. At setting time I raise the temperature about 5° and keep up a rather dry atmosphere—not excessively dry, for the paths and borders are sprinkled daily. Thinning the fruit should be commenced about ten or twelve days after it has set. Muscats require a little artificial aid, but if the weather is fine it is sufficient to shake the rods daily. It can be done by striking the wires with a hoe or a rod of some kind, and the pollen will be seen like a cloud of

dust. If red spider appears, heat and sulphur the pipes, but it must not be done too early, else the effects of it, if strong enough to kill the spider, will also injure the tender skins of the fruit and cause rust. J. DOUGLAS.

## FLOWER GARDEN.

### CHRISTMAS ROSES FAILING.

At page 77, Mr. J. Wood says in reference to the above that he should "feel very grateful for the views of those who have studied the subject," and somewhat earlier your correspondent refers to the niger section of the genus *Helleborus* being in some districts unmanageable. Mr. Wood does not say where the difficulty comes in, or whether the plants thrive for a while or the reverse, and then dwindle away ever after. So far as my own experience goes in the cultivation of these Christmas Roses, I believe one of the most frequent sources of failure to be due to planting and transplanting them at the wrong season. Mr. Wood has very correctly alluded to the differences between these and the so-called Lenten Roses. The latter may safely be planted in most gardens in the spring with the best results. The plants may be divided and replanted in March or April, and given quite ordinary care they grow and flourish freely. This fact is, I believe due in the main to the continuous formation and production of fibrous roots. And here they differ materially, so far as my own observation goes, from the Christmas Roses proper. My own opinion of the proper time for planting these latter is the month of September, early or late according to the season.

I believe that in the niger section of *Helleborus* the main roots are sent forth annually in late summer or early autumn, and only at this time so far as our garden examples are concerned. The object of planting at the time stated then is obvious. I am well aware that in some instances these Christmas Roses are planted with success at other times than those above named, but these are exceptions. If anyone interested will lift a healthy plant late in August, he will in all probability find these new basal or main roots just ready to emerge from the crown in immediate proximity to the spot from whence the current season's growth sprang. To save all such roots intact, and particularly in those instances where one set only is produced annually, is to my mind an important matter to all who would covet a full measure of success. In large specimens these main roots descend into the earth from 2 feet to 3 feet where the soil is good and permits; indeed I have traced them to even a greater depth in very large plants. This at once shows the necessity of a very deep bed. Twenty years ago I had charge of a quantity of grand specimens of the variety major nearly 3 feet across, and when in flower the blooms from each specimen could not have been closely placed in a bushel basket. These plants were grown in cool, fairly moist beds of prepared soil in a sheltered garden, and benefited by distant shade. In the early part of the year, probably when the young foliage is being made, fibrous roots are produced on the main fleshy roots. And in this connection I have observed that these fibres are more numerous on lifted plants than on those not periodically disturbed. For example, those plants lifted late last autumn and placed in boxes or pots for flowering will produce greater numbers of these root fibres this year than is the case with plants not disturbed, but which sent down their roots without any check what-

ever, and it is just this fact that carries the lifted plants over till the ensuing autumn, though by comparison it will be seen that the crowns have suffered to no small extent, and are generally undersized and weakened. This fact I think clearly proves their dislike to frequent disturbance.

Another fertile source of failure in these plants is smoke and close proximity to large manufacturing towns, especially where chemicals are in strong force. In these districts the foliage is early ruined and roots are only sparsely produced. It is a good sign when these Hellebores carry the bulk of their foliage through the greater part of the winter, for there cannot possibly be more positive proof of their perfect health. Much exposure to sun in districts where the soil is light, very sandy, or stony assists in the same direction. In the neighbourhood of Bath, and generally throughout Gloucestershire, Christmas Roses do surprisingly well. The soil generally is of a clayey nature, and in the latter frequently overlying blue lias clay.

Shade in the culture of these plants, especially in light soils, has an important bearing in respect to retaining the foliage. Some years ago I planted a series of hedges of oval-leaved Privet at about 8 feet apart to afford shelter for these Christmas Roses. The plants were hemmed in on all sides save an entrance 2 feet wide. The soil was fairly good, though much lighter than I could have wished. In all cases nearest the base of the hedge, regardless of the direction it faced, and notwithstanding the frequent excessive dryness of the soil by reason of the mass of roots from the hedgerow, the plants were always the most vigorous, and always without exception retained the foliage fresh through the winter; while the manner in which those plants farthest removed from the shade lost their leaves afforded additional proof of the great value of shade of a given kind in the culture of these plants. And it was precisely the same with Hepaticas under the same conditions, thus showing they preferred a similar treatment.

Never transplant these Christmas Roses bodily in huge masses. The old roots apparently have no power to take fresh hold on the soil, no matter what the compost, and the result is they very quickly decay and speedily rot the whole plant if allowed to go on. The soil which seems to satisfy these plants most is a good depth of fairly sandy loam. E. JENKINS.

Hampton Hill.

**A beautiful churchyard.**—There are to be found here and there, in out-of-the-way corners of England, churchyards that possess a restfulness of their own quite apart from the associations of the headstones and "grassy barrows" of the departed; but there can exist few more ideal gardens of sleep than the God's acre at Gulval, lying within sound of the Cornish seas and in sight of the grand outline of St. Michael's Mount, yet far enough withdrawn from the ocean's verge to be embowered in the verdure of sheltering Elms. *Dracenas* and *Phormiums* are growing within the lych gate and a climbing Rose endeavours graciously to hide, with budding sprays, the Latin inscription on the sun-dial above the porch, to the effect that "time is the devourer of all things," which effort will soon be ably seconded by a *Solanum jasminoides* that is breaking strongly close by. Trees of the old *Fuchsia Riccartoni* show their sprouting branches above *Pittosporums*, *Camellias* (red and white), scarlet-berried *Aucubas* and giant *Hydrangea* bushes; while the *Bamboo* and *Cistus* tribes are also well represented. Flowering *Cherry*, *Deutzia* and *Kerria* are only less conspicuous than the pendent wealth of the *Orange* blossoms of *Berberis Darwini*. Here a cluster of

the fair white *Poet's Narcissus* nods above a grave; here the *Forget-me-not* has spread an azure pall; here a loving hand has planted a colony of *Lilies* of the Valley, which will soon be bending white, perfumed bells over the sod. *Anemone fulgens*, a brilliant patch of scarlet, glows amidst the green, and yellow *Daffodils* with purple *Hyacinths* add their tones to the picture. The mistake of over-scrupulous neatness is not made. The shears and the foot-rule are, evidently, not for ever in request. Nature is allowed, within certain bounds, to order her own goings. The spot is a beautiful one now. On summer evenings, with the long shadows of its Elm trees and the scent from the great *Rose* bushes, blossoming profusely from

the attacks of the disease, even when growing side by side with badly-affected bulbs.—S. W. F.

### CHAMÆROPS EXCELSA IN DEVONSHIRE.

THERE are many gardens where this hardy Palm will grow well, its essential requirements being an open, well-drained loamy soil and a position sheltered from wind. A large number of fine specimens may be met with in the south and west of England, assuming that they have all withstood the terrible winter. In this respect it would be interesting to hear how they have fared, for although it has long been proved that they could withstand our average winters, a few extra degrees of cold often commit sad havoc among exotic things not absolutely hardy. The two fine specimens at Heckfield, for example, are in a much more exposed situation than most of those we have met with, one of which, growing in a small back garden in the town of Midhurst and perfectly sheltered, was luxuriant in leaf and flower at the time we saw it.

Mr. C. M. Mayor, who kindly sent us the photograph from which the illustration was prepared, writes as follows:—

The *C. excelsa* and *Dracæna australis* were two very beautiful plants, but the latter has since been much spoiled by the snow of winter 1893-94 being allowed to remain in the crowns. The cold does not seem to affect it so much, as if the tops are killed the stems break freely all the way up, but snow should always be shaken out. Both plants flowered freely. They are planted on the top of a sloping garden, aspect S.E. *C. excelsa* and *Fortunei* make splendid lawn specimens. In this district there are several fine plants of both that have stood well, even last winter, but nearly all the *Dracenas* are without their tops.

*Dracæna australis* and *Chamærops excelsa* in Mr. C. Mayor's garden at Paignton, Devon. From a photograph by Miss Hunt, Southfield, Paignton, Devon.

every shoot, in the air, it will attain an even greater measure of beauty and of rest.—S. W. F.

**Basal-rot in Narcissi.**—This disease seems to be more prevalent among the native varieties of *Narcissi* when grown in beds than when left to themselves in woods or grass. I lately had the opportunity of inspecting a large collection of *Narcissi* in which a good many bulbs of *N. obvallaris* were affected, but one bulb which had found its way into a rough grass plot was growing as strongly and healthily as could be desired. I have seen more than one instance, in the south-western counties, of varieties of *Narcissi* failing when grown in prepared soil, and regaining their health when relegated to the orchard. The heavy trumpet section, such as *Emperor* and *Empress*, as far as my observation goes, seems able to resist

are cased and balled is common earth cut from the mountain sides under the surface soil, which is of a black, porous nature. Water is then added, and it is kneaded well with the naked feet until it becomes tenacious. This is used for balling. The casing material is the same earth, well pounded and dried in the sun.—JAMES CARTER & Co.

**Double Violets.**—At p. 268 "J. C. B." recommends the variety *Queen Victoria* as a substitute for the old *Neapolitan* where this favourite does not grow satisfactorily. I shall be pleased to try *Queen Victoria*, as the *Neapolitan* does not do so well in our district as it does in the south. Has "J. C. B." tried *Lady Hume Campbell*, a splendid variety, and also a capital substitute for the *Neapolitan*? I have grown it for several years and

**Cases for Japanese Lilies.**—The kind of wood from which the bulb cases are made is *Abies firma*, and the soil in which the bulbs

have found it most useful. It has a very hardy constitution, and although of dense growth is not at all liable to damping off in winter as are Marie Louise and some others. The flowers, which are produced in great quantities, are of a beautiful pale blue shade. It has also an additional good trait in its character, that of blooming later in the spring than Marie Louise, no small advantage where a supply of Violets is required as long as possible. "J. C. B." speaks of the difficulty experienced in keeping off red spider. It usually affects my plants but little. This, I think, is mainly due to the position the plants occupy, a deep root run, mulching the surface of the bed, daily summer and frequent evening syringings from the garden engine, occasionally stirring a little flowers of sulphur into the water. Formerly old Violet growers gave their plants a north aspect, and certainly many of them grew the old Neapolitan well, as the more easily-cultivated sorts such as Marie Louise were not then in existence. I think, however, that a position where the sun shines on the plants for a few hours in the morning is best. This strengthens without distressing them. Where the plants are grown on a south or even a due west border spider is always very troublesome, and the growth, in my opinion, is not so satisfactory. Of course in northern counties the case might be different.—J. CRAWFORD, Newark.

#### NOTES ON CROCUSES.

SURELY there is no race of plants that will give more pleasure than the genus *Crocus*. From the early days in September to the middle of April they may be had in flower, in less variety as the days shorten, and increasing in wealth of colours and kinds as the days become longer and brighter. The first to flower is *C. speciosus*, a well-known kind, whose rich blue flowers with their distinct orange-scarlet anthers emit a most delicate perfume. A very fine variety of this is *C. speciosus Aitchisoni*, which was distributed by Herr Max Leichtlin, of Baden-Baden, some years ago. These two are closely followed by *C. autumnalis*, dark purple-blue, *C. sativus*, medium, and a form of *sativus* called *Pallasi*, which has pale lilac flowers, and produces long, fine grassy foliage in early winter. *C. Boryi* is a beautiful white-flowered kind. *C. nudiflorus* has blue flowers, and mention must be made of its pretty white-flowered variety. I have also seen a form of *nudiflorus* with flowers of a most unique shade of flesh-pink. A charming kind is *C. iridiflorus* with its var. major, colour rich blue. *C. cancellatus* var. *cilicicus* is a rare form with large flowers of a delicate lilac blue. These, I may say, close the list of the autumn flowering kinds, but there is no break in the season, for the winter varieties begin when the others leave off. *C. longiflorus*, lilac-blue, is the first, closely followed by *C. hymnalis*, white, with intense black feathering on the outside of the segments; *C. tingitanus*, pale lilac; and *C. Fleischeri*, a creamy white with dark feathering. *C. vitellinus*, which throws up quite a bunch of rich golden flowers, is a true midwinter species. *C. chrysanthus* and its form *fusco-tinctus* are also yellow. *C. Sieberi* has flowers of a distinct shade of blue and is extremely pretty; it has a purple var. *C. Obesi* has a large flower of intense whiteness, with most distinct orange-scarlet anthers. *Crocus Imperati* comes after the dark winter days. Its quaint colouring of lilac-buff and almost black feathering are very beautiful, and the flowers are delicately sweet, but it is surpassed by a variety called *C. Imperati longiflorus*, in which the flowers are larger and the colouring much darker. A lovely form is *C. Imperati albus*. *C. Kotschyanus*, of a delicate shade of pale lilac, outside white; *C. Aucherii*, rich golden yellow; *C. vallicola*, a most delicate flower, the colour scarcely definable; *C. Mæsiacus*, *C. aureus* and its vars., *ochroleucus*, *susianus*, *sulphureus*, are all of various shades of yellow. *C. Weldenii* has whitish flowers with a delicate shading of blue on outside, also *C. dalmaticus violescens*, though *dalmaticus niveus* is

pure white. *C. biflorus* and *C. biflorus argenteus* bear masses of flowers of silvery whiteness with dark feathering. *C. arvensis* is a pretty little kind with deep blue flowers which change to lilac. *C. carpetanus*, *C. Cartwrightianus albus*, *C. Danfordii*, *C. neapolitanus*, *C. odoratus melittensis*, *C. peloponesiacus*, *C. Tournefortii*, *C. veluchensis*, and *C. versicolor* var. *obscurus* are scarcer kinds all with a charm of their own. I need not mention the usefulness of the ordinary Dutch kinds, forms of *C. vernus*, as they are too well known to need comment. All these beautiful and interesting kinds of *Crocus* are of very easy culture, growing well in any ordinary garden soil, but it is well when planting to surround the bulbs with some fine sand. They are specially adapted for little warm nooks, narrow sunny borders, or just inside the edges of herbaceous borders. It is not necessary to lift them every year; they may be left for three or more seasons until the clumps become too crowded, but care must be taken, as mice are extremely partial to them. Some of the more plentiful kinds, such as *speciosus*, *Imperati*, *biflorus* and *versicolor*, are excellent for naturalising in grass. G.

### SOCIETIES AND EXHIBITIONS.

#### AURICULA SHOW.

APRIL 23.

THE Auricula growers had their annual field day at the Drill Hall on April 23, and their exhibits, which were much more numerous than many expected, having regard to the lateness of the season, materially added to what was a very attractive exhibition of plants and flowers. Despite the severity and prolonged character of the winter, it was one of the largest and best exhibitions of Auriculas yet held by the Society. Everybody admires what we may term the Jewelled Auricula—the beautiful and fascinating green, grey, and white edges and the striking selfs, but they can be grown to perfection only by a few. Choice as it is, the show Auricula is a hardy plant—there is probably not a collection in the country but what was frozen hard for many days during the severe weather in the early part of the year, and yet, as soon as the change came, the plants leapt into life and came on at a rapid pace. A little warmth was, no doubt, applied in a few cases to have the plants ready by a certain date, but there was no evidence of their having been drawn; they were in many cases examples of careful culture. The largest class is for fifty Auriculas, but it is high time it was got rid of. It was instituted in the early days of the Society in order to assist the show when exhibitors were few, but now that they are many the necessity for the class no longer exists, and it may be said to include all those flowers which are not good enough to go into the other classes. Mr. James Douglas, gardener to Mrs. Whitbourn, Great Gearies, Iford, was, as usual, placed first, most prominent being three or four yellow selfs, one particularly fine, and Rolt's green edge, which has a red instead of a black body colour, while edged and self flowers were abundant. Mr. A. J. Sanders, gardener to Viscountess Chewton, Brockham, was second, and the Guildford Hardy Plant Company was third, in this collection being a plant of the Rev. F. D. Horner's yellow self Buttercup. Two other collections of fifty were unplaced. The blue riband of the Auricula Show is the first prize for twelve varieties, Mr. T. E. Henwood, of Reading, winning it easily. We give the names of the varieties because they represent a choice selection. They were: Green edges, Prince of Greens, the Rev. F. D. Horner, Abbe Liszt, and James Hannaford, and of these the Rev. F. D. Horner is decidedly the best, but it would be much better if it opened its pips a little flatter, and so did not cup so much. Abbe Liszt is not a true green, as there is a beading of meal round the edges of the segments; but it appears to be a good grower. James Hannaford was coarse and the body colour confused. Of grey edges there were

Lancashire Hero, almost a green edge, Richard Headley, very fine for so early in the season, and George Rudd; of white edges, Acme, undoubtedly the very best when in good condition, and John Simonite; of selfs, Mrs. Potts, the best blue, Black Bess, the darkest, and Heroine. Mr. A. J. Sanders, who is taking a leading position as a successful exhibitor, was second, and Mr. Patterson, who came all the way from Sunderland, third. Mr. Sanders had the best six, having the grey edged George Lightbody as distinct from the before-mentioned, Mr. Henwood taking second place, and Mr. Patterson third. There were several collections of four varieties, and Mr. Sargent, Cobham, who was first, had Rachel, a pleasing grey edge. Mr. W. Smith, Bishops Startford, who had Mr. Dodwell, a white edge, very chaste when in good character, was second. Mr. Sargent had the best two out of nine pairs. Abbe Liszt was selected as the best green edge, George Lightbody as the best grey, Marmion as the best white edge, and Cherub, a dark flower raised by Mr. Douglas, as the best self.

The alpine varieties were numerous, brilliant, and striking; but seeing what a number of new varieties is constantly being raised, is any real progress being made? The notch still disfigures the segments of some; the pistil still protrudes above the anthers, making the flower "pin-eyed," a sad defect in the estimation of the northern florists; and quality appears to be in danger of being sacrificed to mere size. Mr. Charles Phillips, formerly of Reading, and now of Bracknell, Berks, was first with seedlings of his own raising, a very fine strain indeed, remarkable for high quality; Mr. Douglas was second. With six varieties Mr. J. Douglas was first; Mr. Phillips taking the second place; and Mr. C. Turner third, though some thought the first and third positions should have been reversed. Little Gem, Mrs. Gorton, Dragon Fly, Mrs. Martin Smith, Dot, Sophie, Dean Hole, Winifred and Chastity were some of the best alpine. There was a class for four varieties also, Mr. W. L. Walker, of Reading, being first; and classes also for one plant—golden centred and white or cream centred. Some of the varieties staged in the latter class were clearly inadmissible, being yellow rather than creamy or white.

The gold-laced Polyanthuses were mainly seedlings of indifferent character, but as the named varieties went down before the frost, growers were sadly put about for material. There is ample room for improvement in this refined type, if someone would set about it. Two or three old varieties, such as William IV., Napoleon, and Formosa, were exhibited, but they were decidedly poor and are rarely very good.

Brilliant patches of colour were afforded by the fancy Polyanthuses and Primroses, though the Drill Hall is by no means a fitting place on a dull day in which to show them off to the best advantage. Mr. Richard Dean, Ranelagh Road, Ealing, was first with twelve large pots of fancy Polyanthuses, some very brilliant in colour and of fine quality, a golden hose-in-hose form being particularly attractive. Mr. A. J. Sanders was second, and Mr. J. Douglas third. With twelve pots of Primroses Mr. R. Dean was again first, brilliant colouring and fine flowers making a rare display. Mr. J. Douglas came in second, and Mr. A. J. Sanders third. There was no entry in the class for six double Primroses, but in the class for a basket of single Primroses, Mr. J. Douglas was first, though there was scarcely a true Primrose among them, and Mr. R. Dean second.

Fancy Auriculas may be described as embracing anything that does not find a place in the orthodox classes. Among seedlings of the show kinds there are many curious flowers, mainly yellow; laced and double varieties are also included. Mr. Douglas was first, the Hardy Plant Nursery Company, Guildford, second, and Mr. R. Dean third.

Species of Primulas were very fine on the whole, Mr. J. Douglas being the only exhibitor of twelve pots or pans. He had fine examples of *obconica*, *japonica*, *verticillata*, *floribunda*, *Auricula*, *denti-*

culata, intermedia, Forbesi, mellis, decora, rosea, and a somewhat poorly bloomed specimen of laciniata, one of the forms of *P. Sieboldi*. Mr. Douglas was the only exhibitor of a group of species and varieties, these being charmingly arranged in the form of a piece of natural rockery; the subjects repetitions of those mentioned above interspersed with various types of Auriculas, Primroses, &c.

The Premier Show Auricula was a good example of George Lightholy. It was shown by Mr. Collins, gardener to Mrs. Kyrke-Penson, Dinham Castle, Ludlow.

Several new show Auriculas were staged. A special prize of one guinea offered by Mr. W. Smith, of Bishop's Stortford, for the best seedling show Auricula, an improvement on existing varieties, was awarded to a dark self named Favourite shown by the Rev. F. D. Horner, the pip large, smooth, and beautifully formed. Mr. J. J. Keen's special prize of one guinea for four seedling Auriculas, one of each class, was awarded to Mr. J. Douglas, who had Peri, white edge, an unnamed grey and white edge, and a dark self.

Prizes were awarded to two seedling self Auriculas, viz., Favourite (Horner) and Mr. Barnett, also a dark variety, shown by Mr. C. Phillips; it is something in the way of Heroine. Some finely flowered plants of the old double crimson Primrose were shown by Mr. J. Douglas. A group of fancy Polyanthus and Primroses was also staged by Mr. R. Dean.

#### ROYAL BOTANIC.

APRIL 24.

THE exhibits at the second spring show of the Royal Botanic Society on Wednesday were decidedly more numerous, entirely filling the long corridor, and many were placed in the conservatory. There was not much competition for the prizes, but miscellaneous exhibits were of a most interesting character. Messrs. Paul and Son, of Cheshunt, were first for a collection of Roses in pots, the finest specimens being Celine Forestier, Mme. Hoste, Mrs. John Laing, Caroline d'Arden, Beauty of Waltham, Margaret Dickson, and Magna Charta, all carrying many fine flowers. Mr. W. Rumsey, of Waltham Cross, was second. The only exhibit in the class for a collection of hardy plants was that from Mr. T. S. Ware, a good lot, well meriting the first prize. The best things were *Dielytra specabilis*, red and white, *Doronicum*, *Adonis vernalis*, *Ranunculus alexandrinus*, a pretty white-flowered Buttercup, *Geum montanum*, dwarf, a perfect mass of yellow flowers, *Anemone fulgens*, *A. Robinsoniana*, *A. Pulsatilla*, *Orchis fusca*, and a very fine pot of the American Dog's tooth Violet (*Erythronium americanum*). Mr. Douglas sent the only collection of hardy Primulas and received first prize, but there were several decidedly greenhouse species in the exhibit, as, for example, *P. verticillata* and *P. floribunda*, the former named in good free-flowering specimens. *P. Forbesi* attracted much notice, and other good kinds were *P. mollis*, *P. auriculata*, *P. rosea*, *P. japonica*. The best group of Auriculas also came from Mr. Douglas, the plants carrying large trusses of flowers, Mr. Turner, of Slough, being second. For greenhouse Azaleas Mr. W. Barrell, gardener to Mrs. Thornton, The Hoo, Sydenham Hill, was first with a fine lot, showing large, informal bush specimens covered with bloom. The best were Roi d'Hollande, deep red; Dr. Livingstone and Medel, both deep rose; and Magnifica, white. Messrs. Paul and Son were awarded first for a group of Amaryllises, but the second prize lot from Mr. Douglas, though less in numbers, was better as regards purity of colour. Mr. Douglas was the only exhibitor of Cinerarias, and received first prize for a charming group of dwarf freely-flowered plants. A nice lot of Pelargoniums from Mr. C. Turner, of Slough, secured first prize, about twenty-five plants being shown, all well flowered. The best were Purity, a lovely white kind, without any marking; Resy Morn, deep self-

rose; Magpie, white, with conspicuous blotches; Edward Perkins, bright crimson; and Mystery. Begonias from Mr. T. S. Ware were good for so early in the season, the group being relieved by a few Palms and Grasses. The double-flowered kinds predominated. Brilliant, bright red, and Pieotee being good. Among single-flowered varieties, Murillo, dark crimson; Bexley White; Perfection, orange-red; and Regina, white, edged with pink, were the best. Mr. R. Scott, gardener to Miss Foster, The Holme, Regent's Park, was first for a group of Imantophyllums, with large, free-flowering specimens; also first for *Spirea japonica*, showing twelve large plants, well grown and freely flowered.

Among miscellaneous exhibits was a large group from Messrs. Hugh Low and Co., Clapton, consisting of Orchids, chiefly Cymbidiums in fine specimens and Cattleyas, Cannas in variety, and many beautiful New Holland plants now not often seen, as *Correa cardinalis*, *Chorozema Lowii*, *Eriostemon*, *Boronia*, *Genista elegans*, *Acacias*, *Ericas*, and *Epacris*. A silver medal was deservedly awarded. Messrs. J. Laing and Sons, of Forest Hill, arranged a beautiful group of flowering and fine-leaved plants, consisting of Palms, Dracenas, Ferns, and Caladiums, with Orchids, Begonias, and Clivias. A silver medal was awarded. A smaller group from Messrs. J. Peed and Sons of similar plants, with well-flowered examples of *Genista Andreana*, was awarded a bronze medal. Messrs. J. Veitch and Sons sent an interesting group, containing blue Primroses in variety, *Glonera jasminoides*, a well-flowered plant, *Epiphyllums*, *Rhododendron Forsterianum*, *Dendrobium Aspasia*, *Cypripedium Creon*, and *Laelio-Cattleya Epicasta*. Cut Roses were largely shown, Mr. Frank Cant, of Colchester, having many varieties of Teas and H.P.'s, the flowers large and good in colour. Especially fine were Ethel Brownlow, Mme. Cusin, C. Mermet, Ernest Metz, Cleopatra, and Maréchal Niel among Teas, and Mrs. J. Laing, Ulrich Brunner, Duke of Edinburgh, and Mme. G. Luizet among the H.P.'s. A silver medal was awarded. Similar awards were given to Mr. G. Mount, Canterbury, for Roses Maréchal Niel, Niphetos, and Catherine Mermet in quantity; to Mr. Walker, Thame, Oxon, for Roses Maréchal Niel and Niphetos, and to Mr. W. Rumsey for Niphetos and other varieties. A small group of Roses in pots and Azaleas came from Mr. Perry, gardener to Mr. J. C. Tasker, Middleton Hall, Brentwood. Messrs. Barr contributed a large group of cut Daffodils with *Anemone fulgens* and *Muscari*. The best kinds are referred to in our report of the R.H.S. meeting. A bronze medal was awarded. A similar award was given to Mr. Ware for a large group of Daffodils, Spanish Irises, *Gladiolus The Bride*, *Ranunculi* and *Freesias*. An interesting group came from Messrs. Williams, of Holloway, including *Amaryllis* in fine variety, *Leschenaultia biloba major*, *Cypripedium Schrodereri*, and *C. Rotsebildianum* very fine, *Dendrobium Wardianum giganteum*, a good form with broad petals. A silver medal was awarded. Messrs. Paul and Son sent a collection of Cannas, and eight fine specimen plants of *Mignonette* were sent by Mr. W. Barrell. Mr. W. Meads, gardener to Mr. Henderson, Buscot Park, Faringdon, received an award of merit for Melon Countess, the fruits very good for so early in the season.

A full prize list will be found in our advertisement columns.

**The Royal Gardeners' Orphan Fund.**—The usual monthly meeting of the committee took place at the Horticultural Club on the 26th ult., Mr. William Marshall in the chair. A special donation of three guineas was announced from Mr. J. Kipling, The Gardens, Knebworth, Stevenage, received as fees for skating on the lake during the winter. Mr. N. Sherwood has generously agreed to place a child seven years of age upon the fund, to be known as "The Emma Sherwood Presentation." In sending him a special vote of thanks, the secretary was instructed to request Mr. Sherwood to nominate a

child. Mr. Harrison, of Leicester, who took the chair at the annual meeting of the subscribers to the fund, was nominated a vice-president, and a special vote of thanks to him was passed. The secretary laid upon the table the accounts of the annual dinner, and it was stated that a very satisfactory financial result had accrued. Special votes of thanks were passed to Mr. H. J. Veitch for presiding at the annual dinner and to the donors of plants and flowers. Mr. Barron reported that what remained of the fruit and flowers at the close of the dinner was sent to the Hospital for Sick Children in Great Ormond Street, and a letter was read from the lady superintendent gratefully acknowledging the same.

#### DAFFODIL SHOW AT BIRMINGHAM.

APRIL 24 AND 25.

THE Narcissus show at the Birmingham Botanic Gardens on April 24 and 25 far surpassed the two annual exhibitions previously held there both in extent and variety as well as in the extra fine quality of the flowers shown. The large collections from Messrs. Barr and Son, Messrs. Jas. Veitch and Sons, Mr. T. S. Ware, and Mr. Sydenham were in perfect condition and much admired, silver medals being in each case awarded to them. Messrs. Pearson and Sons, of Chilwell, Notts, and Rev. S. E. Bourne, of Lincoln, also had very extensive groups of flowers exquisitely fresh and highly coloured. New seedlings were shown by Rev. G. H. Engleheart, Messrs. De Graaf, of Leyden, and Messrs. Jas. Veitch and Sons, and the first named exhibitor and raiser staged the finest new seedling in the show, a bold and shapely Ajax named Ellen Willmott, having creamy white perianth and a broadly expanded yellow crown. It is in the way of Weardale Perfection, but larger, with a deeper tinted chalice or corona. Mr. Engleheart also had a seedling in the way of Lulworth, but having a more expanded cup of not quite so vivid an orange red colour. The pure white hybrid between *N. triandrus* and *Ajax albicans* was also exhibited, and, like the last, gained a certificate of merit. It is a dainty thing, not inaptly described as a white form of *N. Johnstoni*. The show was well organised and tastefully arranged, but, unfortunately, rain fell on both days, thus preventing many visitors from enjoying perhaps the finest Daffodil show seen since the first Narcissus conference in 1884. Messrs. De Graaf showed a number of seedlings, including F. W. Moore, a noble yellow Ajax in the way of G. G. of Leyden. They also showed fine blooms of Mme. Plump and of a dainty white Ajax named Cecilia, having a green stripe at the back of each of its perianth segments. Some of the visitors to this show were much interested in the new rock or alpine garden now in course of formation in the Birmingham Botanic Gardens by Messrs. Backhouse and Sons, of York. It is a bold combination of rocky peaks and plateaux above a rock pool having boggy margins. A new annex, terminated by a stage for the orchestra, has also been made to the exhibition corridor. Altogether there are signs of well-directed progress and energy in the management of the gardens and exhibitions. F. W. B.

**Effects of the winter at Penzance.**—The effects of the past severe winter, and especially of the biting wind experienced in exposed situations, are particularly noticeable on the sea-front at Penzance. Nearly all the lodging houses had their strips of front garden separated from each other by hedges of *Veronica*; these are now absolutely killed. In one or two cases where *Euonymus* took the place of *Veronica* the shrubs are so damaged that they will have to be cut back almost to the ground level. In the public gardens the large Aloes have been badly damaged, and the Bamboos injured by the wind. Inland, among the Elm trees appearances are not so pitiful, but not a tithe of the Wallflower plantations that were

to be found on all sides at this time last year are to be seen now. In a sheltered spot in the neighbourhood I saw the other day a splendid specimen of *Pyrus japonica* in full flower. The branches covered the whole front of a cottage, and the vivid scarlet of the blossoms against the grey Cornish granite with a setting of blue sky overhead formed a picture not soon to be forgotten.—S. W. F., *Penance*.

### EPHING FOREST.

As one of the so-called "experts" who, at the request of the Epping Forest committee, studied on the spot the question at issue about Epping Forest, kindly let me urge through the *Times* that the report itself should be considered. The trouble arose from the Epping committee having the very common, but erroneous idea that Oak and other forest trees are best isolated—i.e., what they call specimens—and not having the faintest idea of the natural character of a forest, in which the trees are generally tall and massed, the effect being quite different from that of trees in open parks and pleasure grounds. With all his good-will for the Forest and sense of its natural beauty, it was difficult to get even Mr. Buxton to see this, and yet it is evident in all true forest and even in the beautiful Oak woodlands of Sussex. Kindly let me quote the essential parts of the report as regards thinning—and the whole question of Epping Forest arose over the thinning of closely massed trees:—

**POLLARD HORNBEAMS.**—A vast proportion of the area of the Forest is covered by pollard Hornbeams. In parts they are an interesting feature, but the practice of pollarding having been discontinued, the trees are now so dense that neither light nor air can penetrate. We consider that, with a view to encouraging the growth of better trees and varying the monotony of the Forest, the best course will be, not generally to thin the trees, but to make bold clearances among them. The finer pollard Oaks throughout the Forest should be carefully preserved.

**UNDERWOOD.**—Although in many places this forms one of the beauties of the Forest, we do not think that in all parts sacrifices should be made for the purpose of encouraging it where the trees do not allow of its healthy growth, as under Beeches. The effect of closely-massed forest trees constitutes a beauty in itself. In approaching the question of thinning, we think we can best point out our views by taking as examples a few typical parts of the Forest, as it is impossible to lay down any general principle for dealing with so vast and various an area.

**HAWK WOOD** is, in the main, an Oak wood, and the trees are not such as would be improved by wholesale thinning. It would be, in our opinion, wise to take out no trees, except such as are obviously dying, and a few scrubby stunted trees which are injuring the others. Where, here and there, a single specimen of more than usual beauty can be encouraged into noble growth, it should be protected from overcrowding. But we attach great importance to preserving the massive character of the Forest, especially in this wood.

**MOXK WOOD.**—This consists of fine old pollarded Beeches, and, in our judgment, it needs no further thinning for many years to come.

**HIGH BEECH.**—The trees here are of considerable age and beauty, and we do not think that they should be interfered with.

**WALTHAMSTOW WOOD.**—The beautiful undergrowth of Holly is here a distinctive feature. There are a few dead and dying trees which

should be removed, and here and there some pollards, which threaten to injure the Hollies. The healthy Oaks, even where crowded, should be left standing. The beauty of tall Oak stems, often Lichen-covered when growing in close woods, should be considered.

**THEYDON HIGH WOOD.**—Here are Beech trees of moderate age which have not been pollarded, forming a dense canopy of leafage, and constituting a distinct feature. We recommend moderate and periodic thinning.

**LORD'S BUSHES.**—At this point there is a struggle between healthy young trees (Oaks and Beeches) and a number of old pollards, some of which are dying. Having regard to the preponderance of pollards in the Forest, we should, as a rule, let the young trees take the lead, preserving the finer and more picturesque pollards.

These directions, which can be so easily followed, as regards the future of the Forest might well be left to the very competent superintendent of the Forest to carry out, and any bringing in of outsiders or strangers to mark the trees is perfectly needless in the face of such simple directions, consisting for the most part in letting the beautiful Forest retain its natural varied and picturesque character.

SYLVA.

### NOTES OF THE WEEK.

**Tulipa saxatilis.**—Among many Tulips, species and varieties, flowering in Messrs. Barr's nursery at Long Ditton, this one is most attractive by reason of its singular and pretty colour. The flower is of a clear, pale mauve or lilac colour with a rich yellow base internally.

**Magnolia stellata** (M. Halleana) is very beautiful just now in the Royal Gardens, Kew, where we noticed a small bed of it on the grass. Such a position as this suits this Magnolia. Every shoot is covered with white flowers with rather narrow segments and strongly fragrant.

**The Lady Tulip** (*Tulipa Clusiana*).—Several clumps of this on a sunny border at Kew were worth a note the other day. This species likes a warm spot and light soil. The flowers are slender and graceful, white, with a flush of dull carmine on the surface of the outer segments.

**Cattleya Schroederæ.**—I have sent you to-day two blooms of *Cattleya Schroederæ*. I think you will agree with me that it is a very good variety: it opened perfectly white (five weeks since), but since a slight trace of lavender is perceptible.—T. R. CUCKNEY.

\* \* \* A remarkably fine form.—Ed.

**A group of the Snake's head** (*Fritillaria Meleagris*) is in full bloom at Kew. The leaves and bold flowers form quite a spring picture, the flowers varying in colour, but the almost white form is the most pleasing. It stands out better than the curiously chequered purple-coloured kinds.

**Daffodils at Kew.**—These are now in full beauty in the Royal Gardens, Kew. There are several large beds of the leading kinds, bold masses of the several forms being kept distinct. None, however, are so fine as Emperor, the flowers being remarkably large and the leaves very robust.

**Rhododendron Jacksoni.**—This early flowering hybrid kind merits notice not only for its earliness, but also for its bright effect and freedom of flowering even upon small plants. The buds are rich crimson, but expand into flowers of a light rosy pink colour with spots of a darker hue and a distinct band of deep rose down the centre of each petal.

**Strawberry Royal Sovereign.**—Another season has again proved the excellence of this

variety for forcing and its splendid travelling qualities, and though last year was not a very favourable one for pot plants forming good crowns, the plants of Royal Sovereign have this spring borne large clusters of firm and good fruit.—W. G. C.

**Wood Lily and Windflower.**—One of the most charming flower pictures in the garden this week is *Trillium grandiflorum* and *Anemone Robinsoniana*, both in bold groups clustering together and hiding the ground with a dense carpet of pretty leaves and lovely flowers. The *Trillium* is quite happy in a bed partially shaded by Azaleas and growing in a stiff, moist loam.

**Tulipa orphanidea.**—This is another distinct and beautiful Tulip, of which Mr. Barr has a good group in flower at Long Ditton. It is free blooming, the flower of a bronzy yellow colour mottled with brown, and with a conspicuous zone of brown at the base of the flower, which is about as large as that of *T. sylvestris*, but with broader pointed petals.

**Erythronium Hartwegi** is an uncommon, but pretty Dog's-tooth Violet not very easily managed. It has a very long flowering season, strong bulbs sending up several blooms in well come succession. They are of a pale yellow colour, with a zone of a richer and brighter yellow at the base, the leaves beautifully mottled with dark purple on a light green ground.

**Camellias in the open air at Windsor.**—Mr. F. T. Barry sends us from his garden at St. Leonards Hill, Windsor, a box of *Camellia* blooms cut from plants that have been growing in their present position for the past seven years. The plants have had no protection whatever. The flowers are large, richly coloured, the foliage also being very healthy and bright.

**The Chinese Plum** (*Prunus triloba*) is now a mass of bloom on a sunny wall at Kew. Why is not such a lovely thing as this more often seen? The branches are covered with double rosette-shaped flowers of delicate rose, varying in colour somewhat, but only more charming for this variety of shade. A coloured plate was given of it in THE GARDEN, October 3, 1885.

**Primula rosea and Marsh Marigolds.**—A mass of this Himalayan Primrose and the double forms of *Caltha palustris* is very beautiful at Kew. Both delight in a wet, boggy soil. The Primulas are a mass of bloom, and one notices when so many are grouped together the difference there is in the shade, as well as size of the individual flowers, some being deeper in colour and larger than others.

**Fritillaria pallidiflora.**—This tall and handsome species is flowering well at Long Ditton. It is distinct and striking both in leaf and flower. It grows to a height of about 18 inches, the strong stem freely clothed with large glaucous leaves its entire length and terminated by two fine flowers nearly as large as those of the Crown Imperial, and of a pale self yellow colour with a few slight markings inside.

**Menziesia empetrifolia.**—Following in close succession to *Erica carnea* comes this pretty plant. It is allied to the Heaths, and valuable for the rock garden or when grouped near the edges of beds and borders. It has come unharmed through the past winter, and its tufts are now quite hidden by the rich profusion of its flowers, which are large individually, borne in thick clusters, and of a bright rosy-red colour.

**Anemone blanda.**—This shows a much greater tendency to vary in colour than its deeper tinted relative from the Apennines. Two lovely forms that Mr. Barr now has in flower at Long Ditton are *A. blanda taurica*, which has large flowers in pale blue shades of varying depth, and *A. blanda scynthica*, by some called *Anemone blanda bicolor*, the flowers of which are blue on the outside, the inside being pure white.

**Primroses from Winchmore Hill.**—Mr. Perry sends us from his nursery at Winchmore Hill, N., some fine flowers of the double crimson

Primrose, which we should like to see more often in gardens. He also sends us the old blue Polyanthus, the colour of which is very poor and ineffective. We lately saw some fine masses of the old double white Primrose growing and flowering freely along with Trillium and Anemone Robinsoniana.

**The double Jew's Mallow.**—Whilst traces of the past winter are all too apparent in most gardens, one turns with pleasure to those things that burst into bloom as though no unusual cold had been experienced. Among such the double Jew's Mallow is bright and welcome, especially as at Dropmore, where it makes a fine picture at the present time on a wall and allowed to grow in its own way instead of being needlessly restricted and thinly trained.

**Tulipa Greigi.**—The effect of this fine Tulip is gorgeous, and doubtless it will be grown by many when it becomes plentiful and cheap. It is in fine form this week. A dwarf and sturdy kind, its flowers are of great size compared with its stature, and stand up boldly on very strong stems. The flowers are usually of a brilliant scarlet colour, but vary in a welcome way, some being orange red in colour. Its leaves are pretty, too, having numbers of dark brown marks upon them.

**Garden walks.**—The present time is a good one for cutting Box edgings and for rectifying blanks where such have occurred. Where exhausted, the old stock should be replaced by young healthy plants, planting carefully and firming well; this last point is of great importance in this work, as Box does not take well to a loose root-run, especially if a dry time follows the planting. Some weed destroyer should now be applied to kitchen garden walks and the roller run over after the first rain.—J. C.

**Fritillaries in the Grass.**—These are never seen to better advantage than when growing in the Grass, and a large group planted under such conditions is quite one of the features of the present week. The flowers embrace many intermediate shades of colour, from that of the dark-hued typical form to pure white. In many cases three large flowers are borne on each stem. Those referred to belong to what the Dutch growers call the grandiflora strain, and merit that distinction, as the flowers are altogether finer than those of the common wild type.

**Daffodil Queen of Spain in the Grass.**—This graceful and distinct new Daffodil being happily obtainable in quantity, we have already been able to try it in the Grass, and now in its second season it gives every indication of future success, and promises to be one of the best for growing in this way. It is a great acquisition, being so unlike any other kind at present grown, therefore readily distinguished and easily remembered. Its clear yellow colour comes out well in a setting of rich green Grass, and the flowers gain in size as the bulbs become established.

**Ceologyne Dayana.**—I am sending you an inflorescence of *Ceologyne Dayana* for your inspection. It carries thirty-nine flowers and measures 3 feet 3 inches in length. I would be glad to know whether it is usual for this lovely Orchid to produce such long racemes. The plant from which this was taken has two other racemes, one measuring 38 inches, with forty flowers; the third is not yet developed, but promises to be equal to, if not longer than either of those mentioned above. The plant is in vigorous health, the bulbs being very stout.—J. ELLICOTT, *Summerville Gardens, Limerick.*

**Trilliums.**—Several pretty species are now flowering in Mr. Barr's nursery at Long Ditton. *T. grandiflorum*, with its large pure white flowers, is the finest of them all. *T. atro-purpureum* is pretty, with its distinct reddish brown flowers. Both of these have plain green leaves, but two others have their leaves beautifully mottled with dark brown, namely, *T. sessile californicum*, which has a large flower with long white petals, stained with purple at the base, and *T. recurvatum* with flowers of a dark red-brown

colour. *T. erectum* is a lovely kind with large leaves and a white flower. It rather belies its name by a decided drooping habit.

**Sax fraga luteo-vididis** (Schott. and Kot.).—This, the true variety of *S. luteo-vididis*, is now blooming at Exeter (Veitch's nursery), and is a very attractive plant. It must not be confounded with that early-flowering primrose coloured variety often called *S. luteo-vididis*, *alias S. luteo-purpurea*, *alias S. Frederici Augusti*, which, according to Mr. Wolley-D. D., is altogether wrongly named, and should be called *S. apiculata*, which name was given to it by Professor Engler. The true *S. luteo-vididis* (Schott. and Kot.) is so distinct that there is no possibility of mistaking it for the other variety. When not in bloom the plant resembles *Saxifraga calyciflora*, its rosettes of encrusted pointed leaves being arranged very similarly. The flower-stem, produced from the centre of the rosette, is 3 inches long, erect, and bears at the top a cluster of cup-shaped flowers. The corolla, of a deep golden yellow, is surrounded by a hirsute calyx of a pale yellowish green. The contrast between the colours of the calyx and the corolla is most distinct, and the appellation "luteo-vididis" seems most appropriate.—F. W. MEYER.

**Notes from Almondsbury.**—My experience with *Iris stylosa* this winter is a sad one. Large clumps under a west wall are quite dead. Here and there a few new shoots are appearing. These clumps have been here seven years, and I have never even known them to be injured before. *Iris Milesi*, supposed by many to be tender, under the same wall is quite unhurt and promises the same vigorous growth and bloom as last year. *Eremurus robustus* is very strong and good, yet I once lost this in a March snow and frost. A bed quite unprotected full of two-year old seedlings of *Gladiolus Narceianus* promises well. I have grown these *Gladioli* for some four years, and find them vigorous and satisfactory beyond all others. It seems as if all *Iris*es of Asiatic origin like *Iris Milesi* were far better suited to our climate than the African *Iris*es like *stylosa*. Nothing is more useful here than the *Polyanthus Primrose*. My original lot of twenty or so came to me from Miss Jekyll, and I have now hundreds of plants in all stages by saving seed from one specially fine plant. I hope to improve even on what I now have. These look most lovely in the Grass at the foot of Plum trees. A very pretty combination of colour just now is an irregular line of alpine *Auricular*ae, some tall apple-pink *Lent Roses* (*Hellebores*) and at their feet quantities of *Anemone Robinsoniana*. Judging by my *Daffodils*, slugs are not at all sufferers from the cold. Sir Watkin has with me been unusually fine, but the other sorts poorer than usual.—C. O. MILES.

## PUBLIC GARDENS.

**Gift of a park to Liverpool.**—At a meeting of the Liverpool city council a letter was read from the local solicitor, stating that he had been instructed to offer to the city a plot of land covering 108 acres, which had been laid out as a recreation ground. He was not at liberty to mention the name of the donor. There were some buildings on the land, the rents from which would nearly pay for the maintenance, leaving only a small charge on the city. It was decided to accept the gift.

**The Bute House estate.**—A meeting of the inhabitants of Petersham, the vicar, the Rev. W. H. Oxley, presiding, was held last week to consider the proposed conversion by Sir J. Whittaker Ellis of the Bute House grounds into a building estate. The following resolution was adopted: "That in the opinion of this meeting of the inhabitants of Petersham it is desirable that a most determined effort should be made to induce the Crown authorities to follow the precedent of 1883—viz., to purchase the Bute House estate, Petersham, for the use of the people,

and to add it to Petersham Park, and thus preserve for ever to the public as an open space the beautiful grounds which now form so prominent a feature in the foreground view from the pet Thompson's walk." A deputation representing the inhabitants of Petersham was appointed to wait on the Crown authorities, and it was also resolved to ask the assistance of the Corporation of Richmond.

**Open spaces.**—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, W., it was agreed to open to the public towards the end of May the disused burial-grounds of St. Peter's, Walworth, and St. Mary's, Woolwich, lately laid out by the association. It was announced that seats had been placed on the Main Drainage Embankment, E., and by the river at Chiswick, W. It was decided to grant additional seats for Hackney Churchyard, and to offer some for Hammersmith Churchyard, St. Peter's Churchyard, Cornhill, and a garden in Stockwell Road. Attention was drawn to cases of building operations on disused burial-grounds in apparent contravention of the Disused Burial Grounds Act, 1884, and it was decided to take steps to ensure a full inquiry into each case, in order to secure a due observance of the law. The completion of the tree-planting in Whitechapel Road and the laying out of Allhallows Churchyard, London Wall, was announced, and it was agreed to endeavour to obtain as public open spaces a vacant site in Mile End Road, the Brixton Oval, the Copperas, Bromley, E., Walcot and St. Mary's Squares, S.E., a plot of land in Hornsey, an enclosure in Upper Street, Islington, and one of the Jewish disused burial-grounds. Letters were read respecting a site to be laid out by the association in Canning Town and vacant sites in Deptford and Walworth. It was decided to prepare plans for the laying-out of Bromley Churchyard, E., and St. Stephen's School ground, Bow, E., and a correspondence was read between the Earl of Meath and Lord George Hamilton, the chairman of the London School Board, on the subject of extending the teaching of physical training and swimming in board schools.

**Cobbett's Gardening.**—The first and, so far as I know, the only edition of "The English Gardener," by William Cobbett, was published by the author in 1829. It is a duodecimo, and is divided into seven chapters, each of which is subdivided into paragraphs, of which there are 551. The book is without pagination. It possesses a merit which many books on gardening singularly lack—it is well and interestingly written. Cobbett was also the author of "The American Gardener," published in London in 1821.—W. ROBERTS.

**The weather in West Herts.**—April was a warm spring month, the shade temperature on twelve days rising above 60°, while the exposed thermometer at no time registered more than 8° of frost. At 2 feet deep the temperature of the ground rose during the month from 43° to 51°, and at 1 foot deep from 43° to 53°. It is at the present time warmer than is usual at the beginning of May. Rain fell on fourteen days to the total depth of about 1½ inches, which is rather less than the April mean. The sun shone on an average for four and a half hours a day, or for a shorter period than in any April since 1891.—E. M., *Berkhamsstead.*

**What's a fruit?**—At our local flower show we have a class for wild fruits, and there are often disputes as to what constitutes a fruit. I should therefore be extremely obliged if any of your correspondents would kindly give me a good definition of a fruit.—J. HENSHAW.

**Names of plants.**—*Thomas Tyler.*—*Narcissus* Queen of Spain.—*J. R. Allan.*—*Rhododendron davuricum* var.—*T. Down.*—1, *Rhododendron Nuttallii*; 2, *Epidendrum cochlearatum*; 3, *Bletia Serraniana*.—*W. Wright.*—1, *Cypripedium Lawrenceanum*; 2, *Aloe gasteroides*; 3, *Pteris longifolia*; 4, *Pteris aquilina*.—*J. Anderson.*—*Lissochilus Krebii.*—*Constant Reader.*—Harrison's Musk. Yes, it will answer as you suggest.

No. 1225. SATURDAY, May 11, 1895. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## CHRYSANTHEMUMS.

### RAISING SEEDLINGS.

As has been amply proved in the past, the raising of seedling Chrysanthemums is very much of a lottery. Still, when one single sterling novelty like Duchess of York, for instance, can be had from seed, it affords encouragement for still further trial. Of course, if seed is sown, a very large percentage of worthless varieties must be expected. But to obtain such a fine form of the Japanese section from a selection of twenty-five plants was indeed a wonderful piece of good luck. Such returns are encouraging. It seems almost useless to attempt seedling raising of other sections; incurved varieties are in nine cases out of ten poor examples. Much might be done to encourage the raising of Chrysanthemums by offering prizes for home-raised seedlings. The conditions as to time should be unlimited, though it is not possible to treat seedlings like ordinary annuals. Two years really are required before the plants can be tested properly. There is a tendency amongst seedlings to show large eyes the first season, these in many instances being condemned as worthless. If a second year's trial of these were carried out, a greater percentage of desirable blooms would, no doubt, be obtained. Generally raisers of seedlings are so anxious to see the results, that the plants are run up with one single stem and allowed to bloom. Even well-known good kinds exhibit a marked difference both in colour and formation when allowed to develop blooms from the side shoots also. So much does this affect some varieties as to make them hardly recognisable; therefore, in the case of undeveloped seedlings we may expect similar results. The growing of seedlings occupies much space and time. A good plan is to plant them out of doors in some sunny, open situation and allow all that will to flower in the open, even if protection from early frost in a temporary manner is necessary. An idea can be formed of those likely to be worth a further trial, and much valuable space will be saved. Where, of course, space under glass exists for blooming the plants even the first year, I recommend strongly that there they be flowered. Pots 7 inches in diameter are large enough for the first year's growth. No check should occur to the plants in the way of allowing them to become root-bound in their initiatory stages. The one desirable point about seedling Chrysanthemums is that the height of growth and general habit can be controlled by carefully selecting suitable types of growth as the seed-bearing parents. Not so with sports. In all instances the habit of growth partakes of that from which the sport originated, no matter whether it is desirable or not. No form or method of culture can alter this.

Now that work presses heavily in all parts of the garden there is a possibility of the plants that are grown for a variety of purposes being somewhat neglected, except under the most rigid management. One of the most important items in culture at this stage is to keep the plants growing freely by transferring them to larger pots as they require more space for their roots, putting those plants for the production

of large blooms into pots 5½ inches in diameter. For specimens an inch more is not too much at this stage, and those for bushes and late flowers should have 5-inch pots. Pompon, Anemone pompon, and single varieties succeed in 7-inch and 8-inch pots for the final shift. If they go now into 4½-inch pots, at the next shift they may go into those in which they are to flower. In all cases employ a substantial compost, avoiding much manure, although sufficient for the production of vigorous growth must be given. Pot firmly, as if the soil is placed around the roots in a loose way the growth made is not firm.

It is useless to expect blooms of that deep, solid character so pleasing to all connoisseurs of the flower without ripened wood. It is also useless to attempt to ripen or mature it in a couple of months previous to the flowering of the plants. Maturation must proceed along with growth. All newly-potted plants should be kept a trifle closer in the frames for a few days until the roots are running into the new soil, when all the air possible should be given. Plants growing in frames or pits should be fully exposed to induce a stocky growth; in fact, the lights ought to be drawn off them altogether upon all favourable occasions. It is too early to expose them entirely by night without some protection. Plants crippled at the points by exposure receive such a check to growth that they seldom recover. Abundance of space should also be allowed between the plants.

E. MOLYNEUX.

### NOTES ON RECENTLY INTRODUCED VARIETIES.

In supplementing my former remarks upon the newer kinds I would first refer to the incurved sorts. Really good additions to this class are somewhat slow to appear. The attention of raisers is apparently concentrated upon the more showy Japanese, and it is only by chance an incurved Chrysanthemum of sterling merit is added. Thus

J. AGATE was sold as a Japanese variety, and on a second trial has developed into a magnificent ball-shaped flower. It is large, high-centred, and full. The petals are of fine waxy substance and the bloom well finished. Colour pure white. It has an excellent habit, of medium height. The flower-buds one should select for specimen blooms are those that come early.

GLOBE D'OR.—Buff, shaded yellow. This is a flower of medium size, but deep, full, and nicely incurved. The plant is of fairly dwarf habit with good foliage. Do not over-pot this sort. Like most of the type, a 9-inch size of pot is large enough. Choose buds of early formation.

LORD ROSEBERRY.—This variety has scarcely fulfilled the expectations formed of it. Although pretty largely grown, it was conspicuously absent in the flowering season. Another year may bring an improvement, for when the sort was first seen it was an excellent type of the true incurved Chrysanthemum. The colour is a dark shade of rose-purple. It is of good size, well formed, and the plant is not difficult to grow, but the formation of desirable blooms is very uncertain.

MRS. J. GARDINER.—I feel sure we have not seen this variety at its best yet. It was freely cultivated last year, but the season may not have suited it, and I would advise that particular attention be bestowed upon the variety this year. The colour is yellow with a buff shade. It is full, deep, and especially lasting. The blossom is well incurved to the centre, and has a distinct appearance. It has a good healthy growth and is dwarf. The bud selected should be early, and the sort likes generous culture in the matter of stimulants.

ROBERT PETHFIELD.—This has a splendid flower of the true incurved type, but it is a weakly grower. The colour of the bloom is a soft shade of pink, bright and pleasing. Its flowers are large, full, and deep. An extra amount of ehareol may be mixed with the compost for this variety and care be exercised in watering. Buds selected in early September may be relied upon to perfect a good specimen.

C. B. WHITNALL.—Varieties of the class under notice are so rare from America, that this sort is particularly welcome. It produces extra large, deep, well-shaped blooms. The colour is purple, but as the incurved flower exhibits the outer portion of the petals we get a lighter shade. The plant is a strong, dwarf grower and it should have a pot of the large size in common use. Start with good stout plants in the early season and then select late formed buds.

DESCARTES.—This variety and the four that follow belong to the Anemone-flowered section, a very pretty class. The sorts at present are somewhat dull as regards colour—I mean we desire others with red and crimson shades to give more life to them. This done, there is no reason why their cultivation should not be considerably extended. They are easily grown and particularly free flowering, and when grown without being disbudded form excellent bunches of bloom for cutting. The sort above named is a deep crimson-red and a very telling colour. The flowers are of good size, with a well formed centre or cushion, and the plant grows well. There can be no mistake about the selection of buds in the case of the Anemone-flowered if late-formed ones be always chosen.

JUNON.—Silvery blush colour. The most remarkable point in this sort is its well-developed cushion. In this respect the sort is unequalled in depth and form. It is not a strong growing kind, but still a good doer, and one that will be used freely for show, and for cut flowers.

JOHN BENYAN is now pretty well known as an excellent yellow variety, uncommonly free, and of easy culture.

QUEEN ELIZABETH—This variety was introduced at the same time as the last-named, but somehow it is not so well known. I regard it as among the very best exhibition Anemone sorts. Its centre is large and well formed, the guard florets being long and of pretty formation. The colour of the bloom is blush-rose, with just a tinge of yellow in the centre. It has a capital habit of growth.

W. W. ASTOR.—Another most excellent kind, of a light blush-pink shade. The centre is high and showy. It is dwarf and very easily grown. Give this sort a large pot, as it wants much moisture at the roots.

There has been nothing of special note raised for the past year or two among the small types of Chrysanthemums—the pompoms, Anemone pompoms, and so on. Several good single-flowered sorts have been added, the most charming being

PURITY.—This has a most striking and beautiful white blossom. Its green-tinted centre adds to its effect. When grown as a large bush plant and every bud allowed to develop a flower, such a variety as this is invaluable for cutting.

MRS. D. B. CRANE.—This is not new, but it is such a charming single that I have included it in these notes. Crise-pink of a light tint describes its shade of colour, and in every other respect it is an excellent variety, one that should be seen everywhere. H. S.

New American Chrysanthemums.—Novelties from America this spring will number less than a hundred varieties. The principal raisers who are sending out seedlings are Messrs. Spaulding, Homer, Graham, Pitcher and Manda, Vaughan, J. N. May, Hill and Son, Smith and Son. A consignment of Japanese and Californian seedlings is among the number. Mr. Hugh Graham, who raised Philadelphia, the large massive incurved Japanese which was exhibited at the Aquarium

show in November, and to which the silver-gilt medal of the N.C.S. was awarded, is distributing several other novelties, viz., Mrs. Wm. H. Hurley, Mrs. Thos. E. Wiedersheim, and Katherine Leech. C. H. P.

**M. E. Calvat's new Chrysanthemums.**—At the floral committee meetings of the N.C.S. last season M. Ernest Calvat was a prominent exhibitor, and several of his new varieties were awarded first-class certificates. They were *Amiral Avellan*, a large yellow Japanese; *C. Harman-Payne*, a Japanese of a dark purple shade, spotted white; *Directeur Tisserand*, also of the same section, but of an ochre-yellow shaded crimson; *Mr. R. Ballantine*, a carnation-like Japanese with silvery reverse; and *Reine d'Angleterre*, also a Japanese, of a deep mauve and silvery reverse. In each case the raiser asks the unusually high price of 2s. for a plant. M. Calvat's success in this country seems to have induced many of his countrymen to take up the cultivation of seedlings, and there are at least seventeen French raisers announcing the distribution of new Chrysanthemums this spring. Altogether the total number of novelties from the Continent amounts to 345 supposed new sorts. Some of them are hairy varieties, some early, a few late, but by far the greater number are of the ordinary large-flowering Japanese varieties.—CHRYSANTH.

#### CHRYSANTHEMUM NOTES.

**STOPPING THE PLANTS.**—Last year about this time I wrote in THE GARDEN somewhat in favour of a system of pinching the tops out of the plants to hasten or delay (as the case might be) the production of a bloom bud at or about a given time. The plan referred to the growth of the plants for large specimen blooms. After another year's practice, however, I am not at all disposed to recommend the plan generally, for at the best it is misleading. Were all seasons alike, one might furnish data that would be of some assistance to others, but how could such close rules as stopping a shoot on a certain date in 1893 apply to a similar date in 1894? Who can tell which of these two vastly different seasons the present one is likely to follow? I believe, therefore, that by far the better system of culture for large blooms is the one which has now been in vogue for many years past. This mode is to strike a cutting if possible without a little flower-bud at its tip, allow it to take its natural course upwards, and train the single stem to a stick until a natural stoppage takes place. This is caused by the formation of a flower-bud, which is, as a rule, useless for the purpose of blooming, such bud developing into an ill-formed mass of florets. The time a natural stoppage takes place varies according to the variety, from May to June being most usual. Now, the object of topping a plant is to delay the formation of a natural break in an early flowering sort, so that a further stoppage may be timed to a particular date; and also to cause a break in the case of very late sorts, which in a natural way may not be obtained early enough in the season to allow the plant time to perfect the growth of three other shoots and the same number of blooms in time for the November shows. For the latter purpose the system of stopping is commendable, and as the varieties which may be so operated upon are few in number, I will name them: Mrs. Falconer Jameson, Mrs. E. W. Clarke, The Queen, W. G. Newitt and the difficult Mrs. Alpheus Hardy. Curiously, the sorts named are of American origin. I am a little doubtful about Mrs. F. Jameson, but believe that was its first source, although distributed in England. Persons who pay attention to the origin of varieties will have noticed the natural lateness of American-raised ones;

a few early kinds such as Wm. Tricker and Mrs. E. G. Hill only serve to prove the rule. This fact should be borne in mind in regard to matters of growth. For easy culture there are no Chrysanthemums to equal the French-raised sorts. Take *Viviani Morel*, *Mme. Lacroix*, *Mme. Thérèse Rey* among a host of others. In this respect our English seedlings are in the rear, sorts like *Robert Owen* and *Viscountess Hambleton* being anything but certain.

With regard to topping, I may say the late kinds named should be operated upon quite early in May, even in the south. My views upon stopping were considerably modified last season in watching the results of a collection that had been well managed. Up to the month of June no plants could have looked better or grown stronger. They were mostly incurred sorts and had made their breaks in due course. Now after the shoots caused by this break had grown 6 inches long, the tip of each was taken out for the purpose of timing the appearance of crown buds by early September. Consequently the waste of valuable time in a sunless season by the formation of new shoots was so considerable, that the period left was not long enough to properly develop the new growth, and instead of having the flower-buds at the desired date they were late and produced blooms of an inferior character. But a few plants left to their natural growth furnished remarkably fine deep specimen blooms. In that case then, had topping been unknown, the cultivator would have succeeded in his particular object—namely, magnificent flowers of the exhibition type. As an old exhibitor I have practised more than one mode in the growth of sorts, because it is wise in close competition to give all one's resources a trial. I have often succeeded in one way with a variety of peculiar habits when orthodox systems have failed me. I would, however, warn would-be exhibitors with thoughts of topping choice plants to take everything into consideration before touching the same, the position of the garden, whether favouring quick or slow growth; the state of individual plants, whether more forward or backward than the general batch. Only by carefully weighing such items as these can one be in a position to cope with the perfection, from a florist's standard, that the Chrysanthemum is brought to to-day.

Another matter that causes beginners some doubt is the size of pots best for the final stages. I would use two sizes, one for the incurred class and another for the Japanese kinds. In the former case select those of 9-inch diameter and for the latter not less than 10 inches across. Incurred Chrysanthemums may easily be overgrown, but the Japanese sorts are seldom too strong provided the growth becomes well matured. The advantage of pots of good size is that we may stand the plants well apart, say 2 feet, in their summer quarters without much danger of loss of roots through drought. Of course, watering must not be neglected, but the larger the pots the less often are supplies needed. Mr. W. H. Lees (whose magnificent blooms are admired by all and envied by not a few exhibitors) depends principally upon pots larger than I had seen used in many cases, whilst Mr. E. Beckett, another grower of marvellous blooms, employs sizes not larger than the 9-inch. The latter, however, does not give his plants so much room as does Mr. Lees. But what I wish to point out is the fact that here are two growers equally successful with the flower, but who differ on a point that one might consider of great importance. I would advise the use of comparatively small pots for very strong growing sorts for the purpose of restrain-

ing their tendency to produce coarse blossoms. In this category are *M. R. Bahuant*, *Lord Wolseley*, and *Prince Alfred* among incurred varieties, and *Etoile de Lyon*, *Mrs. C. Harman-Payne*, *Duke of York*, and *Mrs. E. W. Clarke* among the Japanese. The above will be found a very good means of bringing out what little refinement such sorts possess.

The style of growth and high feeding with stimulants necessary for the production of show blooms, as a rule, tend to exhaust the powers of the plants for the production of healthy cuttings after the flowering period is over. This then is an item of culture we should see to at the present time of the year. It generally happens that more plants are propagated than are needed to grow throughout the summer for large blooms. These remnants are valuable for future use. Plant them out on any spare piece of ground, and by occasionally stirring the surface soil, as well as freeing it of weeds, little else will be needed until autumn, when the plants may be either taken up and potted or protected outside, and the desired number of healthy cuttings obtained. There is plenty of time, again, to root little cuttings now for the same purpose, and even the side shoots later on may be made available rather than depend entirely upon the old stools for a fresh stock.

The immediate cultural work among Chrysanthemums is open-air treatment, safe protection from cold winds and spring frosts, attention to tying the stems securely, and careful watering. Arrears of potting should be no longer delayed, and the shoots of bush-grown plants should not be allowed to get long before being topped. H. SHOESMITH.

**Too long names.**—Continental raisers seem to be just as persistent as ever in putting into commerce novelties with ugly or inordinately lengthy names. From one or two of the catalogues I quote the following: *Souvenir de Mlle. Hélène Ambanopulo*, *Lutilloux*, *Souvenir de sa Majesté le Tzar Alexandre III.*, *S.M.I. la Tzarine Marie Feodorowna* (two of the longest perhaps on record), and *Souvenir de M. Auguste Nouin*.—P.

**American nomenclature**, if wanting occasionally in elegance, is at any rate distinctive. We seldom find names that have been used for Chrysanthemums before, a fault for which the French, however, are particularly noted. The most striking examples from the States this season are *Brigand*, *Diavola*, *Experiment*, *Bronze Giant*, *Autumn Leaves*, *Octoroon*, *Parting Guest*, *Oakland*, *Millbrook*, *Philadelphia*, *Jayne*, *Nemesis*, *Sunrise*, *Radiance*, and the like.—CHRYSANTH.

**Prices of new Chrysanthemums.**—In striking contrast to the prices asked for some of the new French varieties, it may be mentioned that the American seedlings are offered at an average of 2s. per plant of each variety. This difference alone ought to be some encouragement for our dealers, who are heavily taxed in the matter of importation, to give preference to the productions of the American growers, amongst whose flowers the percentage of good is just as high as in the consignments from France.—P.

**A Chrysanthemum from Japan.**—One of the French raisers is offering a new Japanese variety which is said to have been raised from seed imported from the gardens of the Emperor of Japan, an occurrence which we may suppose to be somewhat common now-a-days, judging by the announcements that have already appeared. It is named after *M. Toukouba*, who is the director of the Emperor's garden at Tokio, and who is referred to by Mr. James Veitch in his article, "The Chrysanthemum in Japan," written for the recently published "Chrysanthemum Year-Book."—C.

## ORCHIDS.

## LÆLIA ELEGANS.

THE origin of this beautiful Orchid was not suspected for a long time after its introduction, its reputed parents being at the time probably unknown to cultivation, but by modern authorities it is considered to belong to the newly-established genus *Lælio-Cattleya* (Rolfe). The founder of this genus has so clearly proved *L. elegans* to be a bi-generic hybrid, that there can be little doubt about the matter. For garden purposes it matters little whether we call it *Lælia* or *Lælio-Cattleya*. Most of the varieties of *L. elegans* are considered to be natural hybrids between *Lælia purpurata* and *Cattleya guttata* Leopoldi, though some are classed as the progeny of the former species crossed with *Cattleya intermedia*. Whatever their origin they are all exceedingly beautiful Orchids, and worthy of the best care that can be bestowed upon them. They may be successfully

garden. The flowers, produced at various times during the summer and early autumn months, last from three weeks to a month in good condition if carefully protected from moisture. They are often from 5 inches to 6 inches across. The typical form is described in a horticultural periodical of 1850, soon after its introduction, as being bright rosy pink in ground colour, pale yellow at the base of the petals, the lip three-lobed, wavy on the edge, the side lobes white, the middle lobe deep purple. This almost exactly corresponds with the *L. elegans* of the present day.

*L. E. ALBA* is a nearly pure white form of the type, with the exception of the lip, which has the deep purple blotch on the middle lobe marked with white and shaded on the edge with a rosy lilac tinge.

*L. E. BLUNTI* is a dark-flowered variety with sepals and petals of a bright magenta-purple. The lip is white, tinged with rose at the base, the front portion being light crimson.

*L. E. BROOMIANA* is described as a dark coloured form, the sepals and petals broad, deep purple at the points, gradually paling to light rose at the base. The lip is intensely and richly

*L. E. MELANOCYLUS* is a pretty variety with light purple sepals and darker petals; lip rosy purple in front, the side lobes white, tipped with bright rose.

*L. E. MOSSIE* is another grand dark form, the crimson-purple ground being sparsely covered with reddish spots. The throat and tips of the side lobes of the lip are deep crimson.

*L. E. NYLLETHA* bears large flowers, the sepals tinted yellow and rose, lightly spotted towards the tips with purple, the petals similar in ground colour, but broader and rather more suffused with purple than the sepals; the lip bright purple in front, paler in the side lobes.

*L. E. PRASIATA*.—This variety has a greenish tinge to the rosy sepals and petals; the lip white at the base and side lobes, the front crimson-purple.

*L. E. SCHILLERIANA* and its varieties *enspatha*, *irrorata*, *magnifica*, and *Wolstenholmicæ* belong to the set now grouped under *Lælio-Cattleya Schilleriana*, and are all considered to be hybrids between *Lælia purpurata* and *Cattleya intermedia*.

*L. E. TAUTZIANA* is a magnificent variety, which has very broad sepals and petals, the former light, the latter deep purple, the side lobes of the lip white, distinctly and finely tipped with purple. There are two yellow blotches in the throat, the front portion deep velvety purple.

*L. E. TURNERI*, the subject of the accompanying illustration, is one of the finest in the genus; in fact, there is no question about its being one of the best Orchids in existence. It was named in compliment to the late Mr. J. A. Turner, of Manchester, and bears very largely richly coloured flowers. The sepals and petals are bright amethyst-purple, with deeper veins, and the lip has a well-defined magenta-purple blotch on the front lobe; the side lobes are white, tipped with light rose.

There are several other varieties of this superb Orchid, all more or less distinct and valuable, some quite unique, but enough have been mentioned to show the importance of the section. A great many varieties, the darker forms more especially, are valuable on account of their flowering towards the end of the summer at a time when Orchids of the best kinds are becoming scarce, and at the late August and September shows well-bloomed plants frequently take very high positions. H. R.

*Lælia elegans Turneri.* Engraved for THE GARDEN from a photograph sent by Mr. W. Taylor, Glasgow.

grown in pots and a good rough open compost, such as suits *Cattleyas*, and are safer rather under than over-potted. It seems hardly necessary here to go into details of culture, which have been from time to time given in THE GARDEN. Briefly, they require the freest ventilation consistent with a suitably high temperature, only sufficient shading to prevent injury to the foliage and an atmosphere not liable to fluctuations of heat and moisture. A suitable temperature is 55° at night, 60° by day in winter, while in the summer 60° by night, running up by sun-heat at closing time to 75° or 80° will be ample. The pseudobulbs attain a height of from 18 inches to 2 feet or over, and usually bear a pair of oblong, leathery green leaves. From between these the seapes are produced, bearing flowers in accordance with the strength of the plant, from three to six being the usual number.

*L. ELEGANS* is a very variable Orchid, discovered originally by a collector for the late M. A. Verschaffelt in St. Catherine's Island, South Brazil, and introduced by him to the Belgian

coloured on the front lobe, the side lobes becoming much paler towards the throat.

*L. E. BLENHEIMENSIS* is a grand form with large and highly-coloured flowers. This and the varieties *Duchess* and *marlboroughensis* first flowered with Mr. Whillans, gardener to the Duke of Marlborough, at Blenheim Palace.

*L. E. EMILI* is a white-flowered variety, not so strong in growth as some of the preceding. The lip has a broad wavy margin of rich magenta, which is intensified in the front or middle lobe.

*L. E. GIANTEA* is a large nearly white form with light rose-coloured spots, rather indistinctly and irregularly marked. The lip is purple, with light violet lines shading to a white base.

*L. E. INCANTANA* has the sepals and petals whitish, suffused with violet; the lip white at the base, spreading and wavy on the outer edges, and, like the front lobe, bright magenta-purple.

*L. E. MEASUREIANA* is a peculiar, but very attractive form, with light yellow sepals and petals, bordered with purple; the lip prettily streaked and spotted with purple under the column, and the usual deep purple blotch in front.

*Oncidium ampliatum majus*.—This fine species produces bright yellow blossoms upon an erect scape, which often attains a height of 3 feet or more. This is much branched, and during the months of May and June carries a quantity of flowers, which, if not sprinkled by water from the syringe, will last a long time in perfection. It is a very showy species and makes a grand plant for exhibition. I have noticed this doing remarkably well this season in several gardens. It succeeds best when placed at the hottest end of the *Cattleya* house with a nice moist atmosphere. It was discovered about sixty years ago in Costa Rica.—G.

*Phalænopsis Luddemanniana*.—I recently noticed a very fine specimen of this grand Moth Orchid with thirteen flowers upon two spikes. The flowers are each about 2 inches in diameter, with pale yellow sepals barred with reddish brown.

the petals about equal or rather smaller in size, bright purple, with brownish blotches, the margins of each being nearly white. The lip is small, bright purple in front, the side lobes white and yellow. This species was introduced by Messrs. Low and Co. in 1864, and is very variable in the colour of its flowers. It is a native of the Philippine Islands and requires but little material round its roots to grow it to perfection. A small quantity of good living Sphagnum Moss to hold the moisture is all that should be attached to the block or cylinder.—W.

**Cypripedium Elliottianum.**—I have received a remarkably fine variety of this from Mr. Joseph Broome, of Sunny Hill, Llandudno. When first imported it is generally a difficult subject to establish, but it is well worth any attention that may be bestowed upon it. The flowers from Mr. Broome are of fine form and substance, the dorsal sepal large, pointed, ivory white, and streaked with brownish crimson veins, the lower sepal similar, but smaller, of a lighter ground colour and not so densely striped. The petals, which stand out at right angles, are nearly a foot across, broad, with undulated margins, spotted with lines of red at the base, which terminate in lines of reddish brown from about the centre. The lip is also large, in form very much like that of *C. Stonei*, ivory white at the base, in front completely flushed with rose, reticulated and veined with a much deeper colour. It is a very fine form, being larger than usual, and the broader segments with the zebra-like stripes are very effective. This species very much resembles *C. Rothschildianum* in nearly every respect, although it is considered to be distinct. One feature is very observable in the blooms; the petals in *C. Elliottianum* stand out stiff and quite at right angles, whilst in *C. Rothschildianum* they are drooping. The best position for this lovely kind is in the East India house.—G.

#### LÆLIA PURPURATA.

**LÆLIA PURPURATA**, one of the showiest Orchids yet introduced from South America, will now be commencing to bloom. It was first discovered about forty-eight years ago and introduced by the Belgian nurseryman, M. Verschaffelt. It flowered in this country for the first time in Messrs. Backhouse's establishment at York, since which time it has always found much favour. This plant is a native of Brazil, growing in the province of Santa Caterina, from whence it has been imported in immense quantities for several years. When not in bloom it forms a striking and noble object, with its long pseudo bulbs and long, leathery, evergreen leaves. These latter often measure between 1 foot and 18 inches in length. To succeed well with this fine *Lælia* the plants should be well exposed to the sun and light, which will induce them to produce strong growths and an abundance of blooms. During the winter months the plants that may not have properly finished their growths should be encouraged to do so by carefully supplying moisture and not allowing the temperature to be lower than 60°. *L. purpurata* commences to make new growths directly the flowers are past, when the repotting should be done as speedily as possible, care being taken to have the pots well drained, and using for compost fibrous peat and Sphagnum Moss. For newly-imported pieces, which should be selected with good dormant eyes, the best plan is to place them in pots or baskets with nothing else but broken crocks, firmly fixing the plants in an erect position. These should be kept in a moist and shady place and frequently sprinkled with the syringe.

During the last few years *L. purpurata* has become a remarkably cheap plant and within the reach of all, owing to the large importations which are frequently arriving. The flowers are

borne on robust peduncles, which carry from three to eight blooms, individually measuring 7 inches and 8 inches in diameter. These appear usually from the middle of May till the end of July, and if kept dry will last quite six weeks in perfection. This plant will no doubt take a very prominent position in all our exhibitions for the next two months, as it is one of the most showy and useful kinds we have for this purpose. A good typical form may be described as having sepals and petals similar, the latter broader, mostly white, but sometimes flushed with pale rose and veined with a deeper shade. The front lobe is spreading, with fringe 1 edge and of an intense rich purple, veined with a very deep maroon, the lines of this colour passing direct to the base through the yellow throat. Where the necessary convenience is at command, this free-flowering *Lælia* deserves a place in every collection. Amongst the named varieties that have appeared from time to time a few are especially worthy of notice.

**L. PURPURATA BRYSIANA** is a very distinct variety, having the sepals and petals of a fine light rose, veined with a deeper shade, whilst the front lobe of the lip is deep rich purple.

**L. PURPURATA RUSSELLIANA.**—A charming contrast when placed side by side with the other varieties. The sepals and petals are white, tinted with pale lilac; the lip is also lilac, but of a deeper shade, veined and reticulated with rosy purple; the throat rich yellow.

**L. PURPURATA SCHROEDERI.**—The sepals and petals of this are pure white, as is also the lip, excepting the tip, which is slightly flushed.

**L. PURPURATA WILLIAMSII.**—This is a richly coloured kind with rose sepals and petals, veined and reticulated with purple; the lip is also of an intense rich crimson-magenta, tipped with rosy purple.

**L. PURPURATA ARCHDUKE** is possibly the deepest coloured kind that has been introduced, the flowers being large, and, like those of the preceding form, distinguished by their broad segments, which in this are rosy purple, the lip being very deep maroon.

**L. PURPURATA MANDALANA.**—This is of the purest white, with three very pale streaks of mauve running down the lip. This is no doubt the purest white form that has appeared.

G.

#### ONCIDIUM CUCULLATUM.

As the plants of this pretty species go out of bloom they may be repotted or surfaced if necessary and put in order for the growing season. All the varieties of this *Oncidium* are found growing at considerable elevations, and will not thrive in a stuffy, heated atmosphere. What they like is a quite cool, moist and airy temperature all through the year. If convenient they thrive well in small pans suspended, though this is not absolutely necessary. A good deal of water being required at the root, the drainage must have special attention. Thus treated they are exceedingly pretty, and the fine flower-spikes produced under these conditions make them favourites wherever grown. The typical

**O. CUCULLATUM** is a native of New Grenada; the flower-scapes are erect, bearing many flowers; the sepals and petals rosy purple, the lip broad, rosy white, shading to white, sometimes wholly rose, spotted with deep purple.

**O. C. CHESTERTONI** is a very bright-coloured form of the type, with narrow sepals and petals, the lip spotted with bright red.

**O. C. FLAVIDUM** is a yellow-flowered variety, quite distinct from the type, but similar in habit and shape of inflorescence. The lip is purple, with a white margin.

**O. C. MACROCHILUM** is a strong-growing, large-flowered variety. The segments are crimson-purple, the lip mauve, with violet spots. Quite distinct from all the others is

**O. C. SUBGENUM**, a variety said to be found at a greater elevation than any other: it is on this account known as "the Orchid of the clouds." The pseudo-bulbs are shorter than in most other varieties and the blossoms are dull purple, with a white spotted lip. This and

**O. C. PHALLENOPSIS** are frequently classed as species. The latter is a charming and distinct Orchid, the ground colour white, with varying purple and crimson markings. All the varieties are well worth growing. They usually flower in early spring and last a considerable time in full beauty. R.

#### CULTURE OF WARSCEWICZELLAS.

JUDGING from the few examples one comes across in collections, these Orchids are usually considered difficult to grow, and it is a fact that in order to be successful with them a good deal of care and judgment is necessary. This and the allied genera *Huntleya*, *Pescatorea*, and *Bollea* are peculiar in having no pseudo-bulbs, and although they require different temperatures, their treatment in other respects is almost identical. The best position for *Warscewiczellas* is a shady part of the *Cattleya* house, more heat than is here afforded causing the plants to be soon overrun by insects, and thereby weakened. A great point in their culture is to obtain strong plants and to keep them healthy by timely attention, anticipating their wants instead of allowing the plants to go backward from want of new compost or other requisite. Small, weakly plants must have very little compost about them, as the roots, though fairly large, are not produced in sufficient numbers to occupy the compost. Strong, healthy plants with abundant leafage, on the other hand, may be induced to push vigorous shoots through a compost quite as substantial as that used for the majority of Orchids, and it is then entirely the fault of the cultivator if the plants go wrong. It was a revelation to me to see recently some plants of *W. Wendlandi* discolor that had rooted through and through a thickness and quality of compost sufficient for a fairly strong *Cymbidium*, and this in a house closely packed with Orchids of various South American genera. There is, however, a limit to any plant's endurance in this respect, and cultivators will be wise to not rush too quickly into extremes with their compost for this or any other Orchid. What should be aimed at is a medium that, while containing no ingredient likely to become sour, or swell into and among the drainage, yet affords ample sustenance for the roots without continual waterings. Very fibrous loam broken into lumps as large as a pigeon's egg, some nodules of charcoal, and some chopped Sphagnum will constitute the basis for large examples, but a very thin layer of this compost must be given, the pots being filled nearly to the rims with crocks. If the plants are surfaced over with Sphagnum after being repotted, this checks evaporation from the compost and does away with a good deal of watering, which is not advisable with newly-potted Orchids of any kind. Small plants may also be grown on cork blocks dressed with Sphagnum, or, if they can be obtained, pieces of Tree Fern stems. A good deal of attention in watering is needed if grown in this way, and the plants are safest with a little fresh growing Moss about the roots. *Warscewiczellas* require no drying off during the resting period, and it is then the greatest care is necessary. I always remove a little of the Sphagnum from about the plants, but not all of it, as it serves the double purpose of a conductor of moisture to the roots and a guide to the state of the compost. It is perhaps hardly necessary to add that in repotting, every particle of decayed soil, root, or root-stock must be re-

moved, and it is a great advantage if in a bad state at the roots to wash every part of the plant with tepid water, carefully avoiding injury to the eyes or young shoots or puncturing the foliage.

Although not gaudy in colour, Warsewiczellas are very quaint and interesting, and amateurs desiring a change from the ubiquitous Cattleyas, Odontoglots, or other easily grown Orchids will find a good deal of pleasure in their culture, the little additional risk stimulating their faculties and leading them to take greater interest in the well-being of their collections. H. R.

SHORT NOTES.—ORCHIDS.

**Oncidium retusum.**—Some flowers of this very pretty dwarf-growing kind are to hand from "J. L." The sepals and petals are of a deep orange, the lip of a very bright shade of the same colour. It

The Winter Green (*Pyrola rotundifolia*). From a photograph sent by Mr. J. C. Smith, Naudana, Penrith.

is a useful species, of dwarf habit, and can therefore be easily accommodated.—W.

**Odontoglossum madrense** (J. L.).—This is a Mexican species and thrives best with a rather warmer temperature than is usually given the majority of Odontoglots. The flower sent is white, blotched at the base of the sepals and petals with chestnut-purple, the lip having a yellow disc. It is also known under the name of *O. maxillare*.

**Odontoglossum Rossi Amesianum.**—Flowers of this remarkably pretty variety come from Mr. James Cypher, of Bath. It is without doubt one of the most beautiful forms of the type, the sepals and petals deeply marked with dark chestnut, the base of the latter being very much barred, the remaining portion pure white; the lip is also white.

**Cattleya luteola.**—I recently noticed this seldom-seen little species flowering in a suburban collection, under the name of *C. Forbesi*. This is a very dwarf growing species, possibly the smallest in this genus, and no doubt is not so largely grown as many other kinds owing to its not having very showy flowers. These are less than 2 inches in diameter and of a pale yellow colour. I think this is a very late time in the year for it to flower, the usual season being during November and December. A shady and moist position suits it best.—W.

**Odontoglossum Edwardi.**—Under this name "J. L." sends me a striking and fine spike of bloom.

Although the individual flowers are small and inconspicuous compared with those of many other kinds in this genus, it is nevertheless a beautiful plant, and should find more favour than it does. The spikes carry a very large quantity of blossoms of a deep violet colour and very sweetly scented. It was discovered by Edward Klaboch and soon found its way to this country, where it flowered for the first time in 1880.—W.

FLOWER GARDEN.

PYROLA ROTUNDIFOLIA.

THIS is a native plant, but so localised and rare that we shall never become familiar with it unless we grow it in the garden. It is quite good enough to merit a place and will well repay us with its beauty for such care as it needs. Its popular name of Winter Green happily expresses the beauty of the plant in winter, with its tufts

family and very attractive at this season. Its large clusters of yellow and white flowers appearing above a mass of deep green foliage make the plant rather conspicuous. The leaves are deeply divided, giving the plant a most beautiful appearance. *Corydalis nobilis* with me does best in the shade, and at the present time there are over thirty clusters of flowers fully open.—W. H.

DAFFODILS AT LONG DITTON.

THE merits of the best known Daffodils in their several sections and the fine display they make in the grounds of those who grow them in quantity are familiar to readers of THE GARDEN. Something, however, may profitably be said concerning recent or little-known varieties, and to facilitate observations, Mr. Barr has this year adopted an excellent plan in his nursery of growing a few lines of all the sorts in several special beds, thus saving much labour in examining them, besides affording ready opportunities of comparison. The varieties of each section or family growing so near each other, it was possible at a glance to distinguish those most noteworthy. Among the trumpet-flowered varieties, W. E. Gladstone and Golden Prince, both of the maximus type, were fine, the former light yellow, the latter of a deeper hue, with a large expanded trumpet. John Nelson has a graceful flower, of a clear self yellow, with twisted petals, and Lady Dorothy is distinct, having short petals of a light yellow colour, with short trumpet of a deeper hue. M. J. Berkeley, also after maximus, has a large, expanded, rich yellow trumpet, and Sharnan Crawford is similar, the edge of the trumpet deeply lobed and the creamy petals gracefully twisted. Dick Sartoris is a distinct Daffodil, the base of the flower on the outside being rich yellow, shading to pale cream at the tips of the petals, which are imbricated and project towards the mouth of the long trumpet.

In the bicolor varieties Dean Herbert is one not much grown, tall and handsome. J. B. M. Camm is superb, a sturdy grower, free flowering, pale in colour, the petals creamy white, the trumpet of the palest yellow, becoming with age nearly as light as the petals. C. W. Cowan has a fine nodding flower on a tall stem with twisted petals, the only bicolor variety having this characteristic. Mrs. J. B. M. Camm, dwarf and fine, and Princess Ida, pale cream with flush of brighter yellow about the mouth of the trumpet, are charming, and W. P. Milner is a dwarf free kind with a flower much like that of pallidus præcox. In the star-flowered varieties C. J. Backhouse is distinct, with a large flower and a rich orange cup. Gloria Mundi is one of the finest, its petals deep yellow and its large expanded cup of a bright orange colour. Beauty has a fine flower, extra broad in the petal and borne on a tall, strong stem. Magog is distinguished by its large, open, rich yellow cup. Princess Mary has fine broad, white petals and clear yellow cup, and Commander is even finer, broad in petal, with a long fringed cup, extra bright in colour.

Among the Barri varieties, Maurice Vilnorin is one that should become popular, being dwarf, free and distinct, with yellow petals and a neat rich yellow cup. Flora Wilson is a grand kind, the petals almost white, the cup edged with bright orange. Dorothy Wemyss has creamy petals and a bright cup prettily fringed at the edge.

**The Virginian Cowslip** (*Mertensia virginica*) is blooming very freely this season at the present time. On a small bed which is made up with peat there are hundreds of beautiful clusters of light blue flowers. It has been in bloom for the past fortnight. The first flowers are just fading, and these have a pink tinge.—W. H.

**Corydalis nobilis.**—This plant is not grown so much as it ought to be. It is the best of the

The Leeds varieties are especially pure in colour and charming in effect, yet perhaps no section of the great Daffodil family is so little known and grown. The finest of all is Duchess of Westminster, which has a flower of fine proportions and exquisite purity of colour. Beatrice, with pure white petals and neat cup, and Fanny Mason are pretty varieties. Gem is a distinct kind in this family, having large flowers with a long cup rather inflated in the middle and contracted at the mouth. Quite opposite in character is Mimie Hume, which has a widely expanded cup. Catherine Spurrel is a free-flowering variety that has been abundant at the shows this spring, having pure white petals and lemon yellow cup. Madge Matthews has a graceful starry flower, with twisted petals and a tube-shaped cup. Princess of Wales and Mrs. Langtry both have pretty fluted cups, that of the latter having a bright yellow edge. Narcissus Nelsoni major, like a miniature bicolor trumpet Daffodil, is a distinct and effective kind, with short, broad white petals and a long neat cup. Two varieties of it worthy of note are aurantius, which is extra rich in the colour of its cup, and Mrs. Backhouse, having a long cup. A fine variety of *N. poeticus* is that called grandiflorus. It has an open, long-petalled flower on a tall stem, the cup edged with deep red regularly defined as a distinct margin round the edge.

#### NOTES ON HARDY PLANTS.

**Megasea africana.**—Under this name I have long grown a very dwarf form with medium-sized leaves of a very thick substance and bright in colour. It is hardy beyond question and blooms earlier than Stracheyi by nearly a month, the flowers, which are borne in crowded spikes, being pure white. So close are the flowers to the ground, that the spikes of blossom present the effect of a white Hyacinth without bare stem. It is a capital subject for the rock garden.

**Anemone blanda**—a superior strain which I received from Asia Minor, and which I had a note about in these columns last year—yet sustains its reputation. The pan of tubers has not been disturbed in any way, and I now have come to believe that the improved features are permanent. These consist of flowers 2 inches to 2½ inches across. The corollas are much fuller—in fact, the petals are partially imbricate. I find blanda seeds profusely and self-sown seedlings come up all round. I fancy that the many washed-out colours one sees now of this are seedlings that have got crossed in gardens with apennina.

**Epigæa repens.**—One does not see or hear much of this, but it is really too sweet a subject to be neglected. I suppose the two chief difficulties with it are the securing of good growing specimens and the provision of suitable conditions of culture. As I have said before, young or seedling plants are the best even if much smaller; then, if you give peat and loam, with some pieces of sandstone to prevent evaporation, you will not be likely to err. Of course the district should be a fairly good one for general gardening, and an east aspect, with shade from powerful sunshine, is all the better. I have found it best to plant in positions somewhat depressed or dish-shaped; this secures to the plant the moisture essential.

**Shortia galacifolia.**—This is now in flower in the open air. It is often asked if this gem is quite hardy. Of course it is, but I will add one fact. One plant now in flower here is on a raised bed in ordinary loam. It has been there for three years this spring without in any shape or form the least protection either from cold or sunshine, and the plant is spreading its leaves as red as Thorn berries. It grows till late and begins early. Always beautiful in flower, the blossom is larger and purer when produced under glass.

**Ranunculus anemonoides.**—Evidently this plant has been benefited by the extreme cold of the past winter. I never had or saw the flowers and leaves finer than now. The flowers came in March, and a succession is promised for some time yet. Each flower is the size of a florin and rosy white. In a moist chink of rockwork a little group is an exquisite picture. A very deep seam of soil is the best. For a plant so humble the roots are both stout and long, and it flowers freely only when the roots are in a suitable medium.

**Anemone Pulsatilla**, which used to be and is probably still called Coventry Bells and Hill Tulip, as well as more generally Pasque Flower, or Easter Flower, is singular for the almost invariable habit of coming into blossom at Easter, even when the winter has been prolonged and severe, like the one just gone. Unlike most other Anemones, it has a decided preference for lime, being found wild on chalk hills. It is also very variable, so much so that some forms are hardly recognised from the more refined and less robust *A. Halleri*. J. Wood.

Woodville, Kirkstall.

#### GARDENING AT PENZANCE.

EVERYONE knows of Penzance as a beautiful Cornish town very near to the Land's End, and together with Newlyn forming a horseshoe or crescent around the shores of Mount's Bay, from the blue waters of which St. Michael's Mount rises like a castle-crowned rock pyramid, just as does its namesake near Avranches, in Brittany. Cornwall is just now very beautiful with its Primrose banks and grey Oak woods, its tender young Larch, and wild Cherries white with blossom; but Penzance is specially interesting, as its inhabitants are so fond of gardening in the fields and even in the heart of the town itself. Broccoli and new Potatoes are largely grown in this locality, and there are fields of crimson Wallflower that have escaped the scathing frosty winds of the past winter, and now fetch a good price in the market. Even here, however, there are signs of the bad weather, even the Gorse bushes being browned and in some exposed places killed to the ground. Conifers also have been badly scorched, and Veronicas, Eonymuses, Myrtles, Bamboos, Blue Gum Trees (*Eucalyptus*), Cordylines, and New Zealand Flax are all more or less injured. Curiously enough, the old and presumably hardy *Rhododendron ponticum* is badly cut, even worse in many places than are the hybrid seedlings. Everyone in Penzance cultivates plants and flowers, and even the windows of the smallest cottages contain plants of many kinds not usually seen in such restricted quarters. Begonias, Oxalis, Fig Marigolds, Mimuluses, Cacti, and Aloes are common, and in the villas the Arums and Azaleas, choice Palms, Ferns, and India-rubber Ficus are beautifully grown. In one window I saw a fine *Sparmannia*, and in others *Pelargoniums*—not only zonals and fancy or show kinds, but even some of the old species long ago figured by Andrews and Sweet in their monographs of these once fashionable flowers. In some little windows Musk and *Saxifraga sarmentosa* are beautifully grown, and everywhere, in front of the houses and trim little front gardens, planted as hedges or on walls, are gold and silvery varieties of *Eonymus*, the brilliancy of the golden forms being most effective. The *Eonymuses* are used here and all along the south coast in many pretty ways, and, as grown on walls, porches and pillars, they form a close carpet of gold or green, quite different in effect and texture from the Ivies so generally used in similar positions in more inland or northern places. There is a

small, but nicely kept public park, called Morrab Gardens, in Penzance, the lawns lying up the slope of the hill facing Mount's Bay. It contains a few groups of Elm and other trees, including Apples, Mulberries, and a quaint old Medlar with a twisted trunk, and evidently planted long before the gardens themselves were formed. A rock-edged pool is filled with aquatics and gold fish, and there is a public library, and a record of temperature, &c., is posted daily on the door. There are here some five clumps of *Bambusa Metake*, and good plants of *Cordylina australis*, *Agaves*, &c., but isolated too much instead of being placed in bold groups.

The fruit trees in the little gardens are full of blossom, and there are little lawns and beds or edgings of Auriculas, Primulas, Arabis, &c., on all sides, and one may safely say that fish and flowers appeal to the Cornish people more forcibly than to the fishermen elsewhere, excepting, of course, those of the adjacent Isles of Scilly. A fertile soil, warm and sandy, and a genial climate no doubt exert a great influence on cultural traits of this kind, and enable the Cornish cultivators to compete successfully in our markets with foreign growers, although they are very heavily handicapped by their produce having to make such a long railway journey. F. W. B.

#### THE AURICULA.

As I write these lines we are within two weeks of the exhibition, and I have not in my large collection half a dozen fully developed trusses amongst the edged varieties. Growers in the north say that no flowers can be out in time. We are now getting very fine varieties in the self class, and these are always ahead of the edged flowers. At the present time (April 9) there are about thirty fine trusses of yellow self seedlings developed in our collection; these of themselves make a fine display. The yellow selfs, although they are to all intents and purposes show Auriculas, have not been good enough to be exhibited as such. The very pretty yellow self Buttercup raised by the Rev. F. D. Horner is far ahead of any other yellow self, and when at its best might very well be admitted as an exhibition variety. For garden purposes there are a number of varieties, yellow with grey, green and white margins, which are very pretty indeed. I exhibited a bronzy yellow a year or two ago under the name of Old Gold, which was certificated.

If the weather continues favourable, the plants make rapid growth after the middle of April, but I would warn fanciers of the danger of forcing them either by artificial heat or exposure to the sun. Artificial heat with little ventilation draws the plant up, the stems are weakened so that they cannot hold the trusses erect, the corolla (or pip) is contracted to half its size, and so poor are the flowers that it does not seem worth while to spend time and money cultivating them. On the other hand, exposure to bright sunshine has a disastrous effect in shrivelling up the flowers as soon as they expand. The best results are obtained by allowing the flowers to develop slowly. They must be lightly shaded from sunshine as soon as the trusses begin to develop and air must be admitted freely, but not so as to expose them to draughts. The delicate texture of the corolla is much injured by exposure to the wind blowing through the house; it is better not to allow this for other reasons. Preparations must be made to re-pot the old plants, and the young off-sets should also be potted on as they require it. Overpotting must be avoided, and the plants should be re-potted rather deeper than they were before. During the autumn and winter season they lose their leaves, leaving bare stems an inch or more in length. When the plants are turned out of their pots part of the old soil should be removed and the base of the main roots examined, as sometimes decay has set

in. All the decayed portion should be removed, and this will allow of the plants being lowered sufficiently to bring the lower leaves down almost to the surface of the soil. Drain the flower-pots well and pot firmly in good loam four parts, decayed manure one part, leaf-mould one part, and a moderate proportion of coarse sand.

As soon as the flowering period is over the plants should be removed to frames on the north side of a wall or building of some kind. In order to get the seedlings to flower well next season they must not receive any check during the summer, and should be potted on as they require it. As the warm weather sets in, green-fly will also increase in numbers, and this troublesome pest must be got rid of at all hazards. I find fumigating with tobacco smoke is the best way to deal with it. The white woolly aphid which attacks the roots is troublesome enough, but it does not do anything like the mischief that green-fly does. In repotting, the woolly aphid should be removed from the roots, especially where it has fastened on the neck of the plants. J. DOUGLAS.

**Ixias and their allies.**—There is a class of bulbous plants represented by the *Ixias*, *Sparaxis*, and *Babianas* that possess the great merits of cheapness, simple cultural requirements, and remarkably showy blossoms totally different from anything else in our greenhouses. Pretty though they be, these plants are very seldom seen. A great many are grown in the Channel Islands, and large numbers are sent from there in the shape of dry bulbs during the autumn months. They reach here as a rule about the same time as the Tulips, Hyacinths, &c., from Holland, where also the *Ixias* are largely grown. A very convenient way of growing them for greenhouse decoration is to put about eight or ten bulbs in a pot 5 inches in diameter. A frame or a light position in the greenhouse will suit them well in the winter, during which time care must be taken not to over-water them, as the roots will not be particularly active, and in all stages the plants are very impatient of an excess of moisture. This must be particularly guarded against when they are planted out of doors, as in a nice warm border in the front of a greenhouse and facing the south they will in some places do well. As they commence to push up in the spring care must be taken that they are not allowed to draw up weakly, otherwise a good deal of their beauty is lost. When grown in pots the bulbs generally become weaker after flowering, but they can be obtained at such a cheap rate that they give a good return for the outlay the first season. The long wiry stems of these plants stand them in good stead when they are used in a cut state for filling vases and similar purposes.—H. P.

**The Daffodil bloom in the south of Ireland.**—This has been a most protracted season of bloom, more so than for fifteen years within my recollection. Flowers of Ard-Righ, that I always had out of doors at the end of January, were not gathered until the second week in March, and now the third week in April I can gather from nearly every known section. The bloom in quantity has not been that of other years—a general remark applicable to old clumps established in grass, such as *Priniceps*, *Telamonius plenus*, &c. In a cottage garden close to this place I have been always admiring the quantities of blossom on some large clumps of *N. priniceps*, where not even one flower appeared this season. Another notable occurrence: Every grower of Van Sion for market will from year to year remark how a season changes the colour and solidity of his flowers. This season—the first for three or four—Van Sion has been very satisfactory, and, what is better still, the flowers have been nearly all solid trumpets, not split up, as in other years. I think the previous summer's hot sun did the mischief in the splitting up of bloom, because I have always noticed more of the effect in hot south borders where the bulbs are not disturbed than in moist northern positions where they have a cool bottom during the resting period. The deeper

one plants the old double white *Narcissus*, and the moister the position, with ample drainage, the larger and finer the flowers. After all, I have come to the conclusion that all sorts of *Narcissus* thrive best in grass. There is an estate not far from here where for over 150 years *Telamonius plenus* has been allowed to grow undisturbed on a portion of meadow land, which is irrigated annually, and I never saw the blooms finer and more numerous.—W. BAYLOR HARTLAND, *Ard Cairn, Cork*.

**Tufted Pansies from cuttings.**—To raise stock of these plants it is generally recommended that the cuttings should be struck in a frame. I find no necessity for this, and for some years I have put the cuttings in an open border facing west, and here they have struck freely and well, the young plants being stronger and healthier in every way than they were when I used a frame. Even during the past winter not one of the cuttings was injured by the frost, and they emerged from their covering of snow in excellent condition for planting. One strong argument in favour of this plan of striking out-doors is the extra room that can be afforded to each cutting: they are also not debilitated by confinement or neglect of ventilation. I find it a good plan to bury the cuttings very nearly to their tips, as they are not then so liable to suffer from drought. Varieties in both sections that have done well with me are *Violetta*, *Sylvia*, *Quaker Maid*, *Holyrood*, *Bullion*, *Glow*, *Souvenir*, *Golden Bedder*, *The Mearns* and *Perfection*. Besides these I have many home-raised seedlings that have appeared good enough to keep, among them a pure white and rayless tufted Pansy.—J. C. TALLACK.

#### LATHRÆA CLANDESTINA.

SOME years ago, in 1889, I think, some notes appeared on this pretty and interesting parasite which evoked some interest. Since that time the plants here have travelled about 15 feet in a westerly direction and none are to be found nearer than this to their old position. They do not spread themselves about indiscriminately, as all the tufts appear yearly within a shifting radius of 2 feet. This year there are in all sixteen tufts composed of from three to thirty crowns, each crown bearing from ten to fifteen buds, so that when the deep violet flowers, each as large as, and something like in general appearance to an ordinary *Crocus*, are out, the mass makes a very effective bit of colour in its setting of grass. It would be interesting to know of other places besides Kew and the Botanic Gardens at Cambridge where this plant thrives, and also what the best means of propagation may be. Given a proper host and a knowledge of the best means of procedure in introducing the seeds upon it, this would seem to be the proper, if not the only way, as the seeds are very freely borne. Care in collecting the seeds would be necessary, as when they are ripe they spring from the capsule with great force immediately the latter is touched and are easily lost. Kerner, in his grand work, "The Natural History of Plants," which has lately been brought within the compass of English readers, has devoted much space to parasitic plants. Writing of this plant, he says:—

The seed of *Lathræa* germinates on damp earth. The young root of the seedling grows at first at the expense of reserve material stored in the seed, penetrates vertically into the earth and sends out lateral branches, which, like the main root, follow a serpentine course, and search in the loose damp earth for a suitable nutrient substratum. If one of these meets with a living root belonging to an Ash, Poplar, Hornbeam, Hazel, or other angiospermous tree, it fastens on to it at once and develops suckers at the point of contact. . . . These discoid suckers cling to the roots attached by means of a viscid substance produced by the outermost layer of cells.

Before reading this I had intended trying what might be done by inserting seeds in incisions made in the roots of trees selected as probable hosts. This would apparently be unnecessary, even if it did not entirely defeat the object in view. I do

not feel quite satisfied that growing the plant from seed is quite so simple a matter as the above extract would lead one to suppose, otherwise, from the thousands of seeds which must have been widely scattered here during the past eight years, unless they have been eaten by slugs or other insects, the plant would be more plentiful and have a wider range, for the conditions are evidently suitable, the soil is always moist, being at the bottom of a valley and close to a pond, and full of the roots of various trees. Eight years ago the plant was nesting at the foot of a deciduous Cypress: near this was a Portugal Laurel as well as Box bushes. There are also Horse Chestnut, Elm, Holly, Beech, and other trees near enough to have extended their roots to the spot. The tree nearest the parasite at present is a young Sallow about six years old. Tracing the plant to its host has been out of the question, as it would mean destruction to the *Lathræa*, but this year one tuft is so far removed from its neighbours that it may be possible to trace it home without doing any damage. J. C. TALLACK.

#### A SCOTTISH PRIMROSE GARDEN.

WHEN seen in the mass, acres of Primroses, as they are flowering here at present, are delightful, the soft ripples of colour flowing over smooth reaches of lawn, straying over mounds, wimpling in little hollows, or, prettiest of all, surrounding and lapping the bases of grey old Beeches or Planes whose holes are covered with Lichen. The colours of the flowers are nearly all of soft shades and white, but, curiously enough, among the tens of thousands that bloom year by year, one truly wild form is never seen. There are indeed yellow flowers in abundance, but none of the same shade and particularly of the same form as the native Primrose. The plants, moreover, are remarkable as being somewhat erratic in the way they leave one part of the ground and form fresh colonies in erstwhile bare spots. Portions that nearly thirty years ago were thickly covered are to-day almost bare of plants, and other places that twenty years back were green are to-day bright with bloom. Another peculiarity about these Primroses is the scarcity of large plants. Almost without exception they are single-crowned, and where clumps of one colour are established they are apparently the produce of the seeds contained in one capsule. I have noticed this peculiarity more particularly in the case of some plants that were a dozen or more years ago planted out in a bare corner. Seedlings from these almost always appear quite close together in little groups, and the flowers in each group are nearly always of the same colour. This would show that these blooms left to Nature are seldom cross-fertilised, and it further points to these as a valuable addition to those flowers we can enjoy in groups of one colour, nothing being simpler than raising Primroses from seed.

How long these semi-wild plants live it is impossible to determine, but, judging from the difficulty of keeping Primroses and Polyanthus for any length of time in the garden adjoining, I believe they are very short-lived. It adds something to one's interest in these plants that their origin is involved in obscurity. At the commencement of the century they were very numerous, though not so much so as now. The history of the Tynninghame wilderness, which these Primroses do so much to beautify, begins just previous to 1707, when a comparatively small piece of ground, planted by the third Earl of Mar about 1637 to 1640, was so far added to by the celebrated tree planter, the sixth Earl of Haddington, as to form an enclosure of over 14 acres. The ground was trenched and laid out in the French style, with a centre, from which fourteen walks radiated in different

directions. These were bordered with trimmed hedges of various kinds of trees, one that sounds very pretty having been planted with Laburnum alternately with Mountain Ash. One can imagine the beauty of the embowering Laburnums in May and the Mountain Ash in autumn when gay with fruit. The interspaces between the alleys were planted with a variety of trees, of which Beeches and Planes are to-day superior to any others, though a quarter of a century after they were planted Elms and Ashes were growing the most vigorously. There are now none of the latter, and the Elms are all in a decaying condition. The lines in Thomson's "Spring," beginning

At length the finished garden to the view  
Its vistas opens, and its alleys green,

apply with the utmost exactness to what must have been the general appearance of Tynningham and its surroundings at that time. The poet was intimate with Lord Binning, having acted as his tutor, and was most anxious to dedicate "Spring" to his fellow countryman. If we then conclude that here indeed was "Yon mingled wilderness of flowers," the Primroses of the present day must be direct descendants of plants first set out 190 years ago.

Fifty odd years after the wilderness was laid out great alterations were effected on the grounds in the near vicinity of the house. Probably at this period the hedges and alleys were destroyed and the grounds laid out in the natural style, and the flowers would begin to spread. The last of the hedges was not removed till some thirty years ago, when the trimmed Lime tree fence enclosing the bowling green was, on account of old age, grubbed up. Mahonia was planted instead, but it did not succeed, and lately a Yew hedge has been substituted, which in spite of the dry gravelly nature of the soil is progressing very favourably.

In addition to Primroses there are innumerable bulbous plants, two kinds of which, however, never flower. There are also a few Cowslips, which most unfortunately do not increase. An interesting feature in connection with semi-wild bulbous plants is the charming variety among the seedlings. For example, among Snowdrops there are kinds of all sizes, ranging from the tiniest forms to some as large as *Galanthus plicatus*. I noticed a variety this spring with its outer segments increased to six. Mr. Arnott, to whom I sent a flower, considers it quite distinct. Then in Daffodils, I lately picked out over a dozen distinct forms of *Narcissus minor*, the smallest being even less than minimus and the largest and finest an improvement on its parent.

*Tynningham.*

R. P. BROTHERTON.

#### FLOWER GARDEN NOTES.

SUMMER PLANTING.—It is impossible to lay down any hard-and-fast rule as to the arrangements to be made with summer bedding plants. It sometimes happens that the owner has a taste in a particular direction which the gardener has to follow, and even if this is not so, much depends on the style of the garden, its natural surroundings, the size and shape of beds, whether they are isolated on turf or form part of a geometrical design, and many other considerations. There are, however, one or two rules always applicable that may be noted. In the first place, faulty and incongruous mixtures should be avoided, and if a certain number of mixed beds are required—whether they consist of two, three, or several colours—the arrangement requires a considerable amount of taste. This naturally does not refer to plants of the same species as seedling Verbenas or Petunias. Small beds, especially if they are close together and form part of a complicated design,

should be filled with only one variety, with perhaps a single plant of graceful habit to relieve the dwarf carpet. Plants for small beds should also be on a correspondingly small scale. Thus, West Brighton Gem, Surprise, Golden Harry Hieover or Mangiesi Pelargoniums would be far better than, say, Lucien or Amaranth, and the Violetta strain of tufted Pansies better than the Countess of Kintore type. Again, for large beds, if the old-fashioned plan of a centre block and an edging is adopted, the latter should be sufficiently wide to show itself to advantage. A narrow edging or two separate bands of colour from the centre is a style of planting not to be commended. I said above, that a mixture of colours in one bed should be avoided. This applies to several varieties of similar height and not to the judicious blending of a few taller subjects on a dwarf carpet, possibly when well done one of the most pleasing features of summer bedding. In the case, for instance, of tuberous Begonias—free flowering and of vigorous habit, but with the flower-spike inclined to droop—they were formerly planted thickly in order to cover the ground, and under such conditions there was a natural complaint that the greater portion of the flowers could not be seen, and in this case a combination of colour has been made with advantage by planting the scarlet, crimson and pink shades thinly on a carpet of variegated Mesembryanthemum, and the lighter colours on *Sedum Lydium*. In beds of larger size the Fuchsias may be employed as previously recommended, and similar standard or pyramidal plants of Ivy-leaved Pelargonium with the dwarf Pelargoniums noted above as suitable for small beds. Also the mingling of flower and foliage is sometimes very effective. The beautiful variegation of *Abutilon marmoratum* is seen to the best advantage on a bed of purple Petunias, and *Humea elegans* and *Grevillea robusta*, to instance two plants of graceful habit, may be used with many dwarfier subjects. Before passing from the planting of large beds it cannot be too strongly enforced that they should be filled with plants of larger growth, especially where they are standing alone on turf. Large beds that occupy a space of say from 100 square feet to 200 square feet should never be filled with plants like the ordinary Pelargonium or Begonia. If it is deemed advisable to go in for good blocks of flowering plants, tall Fuchsias, Marguerites, free-blooming Cacti and pompon Dahlias, summer flowering Chrysanthemums and Pentstemons rank among the best plants for the purpose. It may, however, be added that in the case especially of larger beds, herbaceous plants of strong vigorous habit and a well-sustained flowering season are the more suitable.

Mixed beds have increased rapidly in favour, until now they may be found to predominate in many flower garden arrangements. In connection with such beds it may be noted that they form an interesting feature when well planted, but are very objectionable if the planting of them is left until the stock is nearly exhausted, and they are then filled thickly with a lot of odds and ends that crowd one upon the other so soon as they begin to grow, so that there is no proper development of individual plants or a general tone of harmony to the bed as a whole. Having decided on the character of mixed beds, it is well to plant first thinly those things that are to be the leading feature, and afterwards to fill in with others that will associate well with them. Scented Pelargoniums in variety that make a comparatively poor show from a flowering standpoint, but which are often very useful for cutting, through the summer months, may form the groundwork of one or more mixed beds, and the majority of them will grow into bushy plants of large size if sufficient room is allowed at planting time. The best of the annuals, as Stocks, Asters, and Zinnias, are sometimes used to fill up such beds as are under consideration, but the practice is hardly to be recommended and is apt to lead to a very incongruous mixture. Writing of annuals reminds one that where they were sown in box or frame with the view that they should presently occupy a some-

what prominent position in the garden, they should be pricked off as soon as they can be handled with the idea of securing good plants. As this month will be a busy one in all flower gardens where bedding plants still predominate, it is advisable to push forward at the present time any work that can be done. East Lothian Stocks, for instance, that have been wintered in frames can be planted at any time, and if the stock is somewhat limited owing to the severe weather in February, they may occupy portions of beds to be presently filled by the spring-sown Ten-week. Any arrangements into which hardy plants enter may, so far as these are concerned, be pushed forward—plants, for instance, like the silvery Veronica, the variegated Grasses, and the like. A broad edging of one of the larger Grasses, the striped *Digraphis*, associates well either with another hardy plant, as *Fuchsia gracilis* or with *Dahlia Fire King*. It has, however, a Couch-like propensity for spreading and should not be introduced among plants of dwarf or tender habit. No mention of hardy plants, especially at this season, seems complete without a little note as to tufted Pansies; they are coming out fast now. The weather experienced in February which was responsible for keeping them back has altered their respective seasons, or rather all are coming into flower simultaneously. There are no specially early-flowering varieties this year.

## GARDEN FLORA.

### PLATE 1013.

#### THE AUSTRALIAN LILIES.

(WITH A COLOURED PLATE OF BLANDFORDIA FLAMMEA VAR. PRINCEPS, B. NOBILIS AND B. MARGINATA.\*)

WHILST many good old plant growers are regretting the gradually lessening interest taken in the culture of New Holland plants in general, that of the Blandfordias also appears to be in the same danger of being overlooked. More skill is needed to produce a healthy example of a New Holland hard-wooded plant than obtains in very many instances of present day favourites, and the same thing applies to the genus now in question, but surely this should not in any way act as a deterrent to their culture. It should rather be an inducement to plant lovers to enter into their cultivation with zest so as to overcome any apparent difficulty. One essential, and that a primary one, is a light greenhouse or pit in which to grow Blandfordias, wherein a free circulation of air without exposure to cold currents can be maintained; an ash bottom from which some amount of moisture arises is also no small consideration, but overcrowding or overshadowing by larger plants should be studiously avoided. Two means of propagation are available, that of raising seedlings and that by offsets; the latter is the course usually adopted, but it must not be repeated too frequently or be done in too severe a fashion. Personally I much prefer to grow the Blandfordias in nearly all peat to peat and loam in more equal parts. Peat seems to be more congenial to them, but, as in the case of hard-wooded plants, it should be made quite firm; charcoal is a good addition when the peat is disposed to be at all spongy; sand should in any case be freely used. Potting should be done early in the spring or soon after flowering, but care must be taken not to overpot in the slightest degree. Rather than let them dry off absolutely, I prefer to see some symptoms of leaf growth remaining; the process of drying off too

1 - Ranunculus repens L.  
2 - Ranunculus acris L.  
3 - Ranunculus abortivus L.

severely will often cause injury. It is surprising that such beautiful plants as these are not more admired than they are. Those kinds figured in the accompanying coloured plate represent three quite distinct varieties or species. *B. flammea* var. *princeps* is undoubtedly the finest kind in cultivation; it is a truly noble-flowering plant; the other two are very distinct. Two other species are specially worthy of note, viz., *B. aurea* and *B. Cunninghami*, and to make up half-a-dozen, *B. flammea* would be a good addition. It should be added, in conclusion, that the habit of growth and the appearance when in flower are all that one could wish.

PLANTSMAN.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**HAND-LIGHT CAULIFLOWERS.**—On early borders the first batches of these will now be so forward that removal of the hand-lights will be necessary, the latter now coming in useful for placing over Vegetable Marrows or similar tender subjects. Presuming that the number of plants was reduced as advised some time ago to three in each light, these will now require steadying by placing some fine loamy soil around the base of each, firming the same with the hands to keep the plants in an upright position and to prevent them from swaying in windy weather. Previous to earthing up, however, I would advise giving a good sprinkling of some quick-acting fertiliser, guano for instance. This will often have the effect of inducing a rapid growth and save the plants from buttoning prematurely. Indeed, the same remark applies with equal force to the younger spring-planted lots of this vegetable, as cold east winds have given them a severe check this season.

**EARLIEST BRUSSELS SPROUTS.**—These sown in February and gradually hardened off after being pricked out into boxes or frames will be in a fit condition for planting now. Select a plot which has been dug for some time and has become somewhat consolidated, as if the plants are put into loose, newly turned soil an unsatisfactory growth will probably follow, with the result that instead of hard knobs forming in September and October, Cabbage-like offsets will form the whole length of the stems. Be the ground ever so firm it will, unless clayey, be benefited by treading before putting in the plants. If the plot has now to be prepared, it will be best to refrain from the use of very rich manure for this early crop, this also producing the evil above referred to. Mushroom manure is very suitable; then if the summer is hot and dry, manure water can be given when the plants are in full growth. Allow plenty of room between the plants and rows for the ingress of light and a free circulation of air, plant with a trowel and firm well. On light soils it may be advisable to also water the plants, and a watch must be kept in wooded districts, as wood pigeons sometimes do much damage to these early green crops. Before planting, draw out a moderately deep drill, such holding the moisture about the roots. On strong soils, however, planting on the level is advisable. Seedlings in the open now well above ground should be freely thinned out; and if covered with netting as a protection against chatfinches, the best way is to remove this, thin out the seedlings, and replace the net for a time, as these pests will often pull up the young plants from sheer mischief after they have grown an inch. The same remark applies to Turnips.

**ASPARAGUS.**—In forward localities cutting will now have become general. Some judgment is needed in this work, as if the knife is thrust too deeply down, the crowns are much injured and future supplies lessened. It is often necessary in warm weather to go over the beds twice daily, in early morning and again in the evening, as the grass soon runs up, and if not cut, opens at the tip, which does not improve either its appearance

or flavour. In regard to storing it until wanted for use, the best way is to place damp Moss in the bottom of a large pan or earthen vessel, and after bunching up the Asparagus not too tightly, to place it on the Moss; this will supply it with sufficient moisture. When placed in water and kept for some days it absorbs too much moisture, and mould is very liable to set in. A cool, dark place is the best. Where blanched Asparagus finds favour the stools should now be covered with some light material, such as leaf-mould, cocoa-nut fibre, or fine soil. This should be arranged in the form of a mound, about a foot in depth; the Asparagus will push up through this, and when the pink tips protrude through it should be bent before it loses its colour. If a broadcast sprinkling of artificial manure was given when the beds were cleaned and surface-stirred, another may now follow, in showery weather. Beware of cutting young beds too hard, as nothing is more ruinous than this practice. Indeed, the same may be said of established beds. A little assistance may now be given to plants that were put out in March, this also having the effect of keeping the roots near the surface.

**EARLIEST CELERY.**—Where an extra early supply of Celery is expected, from the first to the second week in the month will be a good time for removing properly hardened off plants of Sandringham or Early Rose into the trenches. If the latter were prepared as advised some time ago the soil in the bottom will not need treading, but if the preparation has been postponed till now firming will be necessary. Allow plenty of room between the plants, and be sure that they are well watered the day previous to lifting from frames or boxes, or much of the soil will fall from the balls, which is an evil. In exposed gardens it will be necessary to screen the tender foliage from cutting winds by means of a few Yew boughs stuck here and there in the trenches. Where the soil is light and at all inclined to be dry, watering as soon as transplanting is completed will be necessary, but not on strong land. If any suckers cluster around the base of the plants they must be removed; and if possible select a dull, quiet day for planting. This last remark applies to all subjects possessing delicate fibrous roots, a few plants only being lifted at a time. The later crops of Celery must be attended to in regard to pricking off, and if cool frames are not at command, any odd sheltered nook or corner will answer well, giving the roots a good larder and affording some kind of shelter in bad weather. Plants brought on in this way often do better as a main crop, and are less subject to bolting in autumn than are those which are rooted in more heat or on hotbeds. The great point to be observed with heat-raised plants is to remove them to cool quarters directly the seedlings appear through the soil, and to thin out rigorously immediately they can be handled. It is not yet too late to sow seed where there is plenty of spare ground, as even if time cannot be given to blanching, the plants can be used for soups and flavouring generally, and thus the main crop saved for more important uses. For this purpose Leicester Red is as hardy and good as any.

**FRENCH BEANS IN THE OPEN.**—A few rows of some hardy variety may now be sown on a warm south border. Where this is not available sowing should yet be postponed for a fortnight. I prefer Syon House or Ne Plus Ultra for first sowing out of doors. Some recommend Canadian Wonder, but this is so apt to decay if the weather is at all showery and the soil not of the lightest. In sowing, place if possible some light potting soil or similar compost in the drills, which must be shallow. Two inches deep will be quite sufficient, as a little soil can easily be drawn up to the plants when a few inches high. Sow plenty of seed at this date, and also some extra in a warm corner, in order that any blanks which occur may be made up. Nothing gets cleared off sooner by slugs or snails; therefore the moment growth appears, a good dusting of lime, or soot and wood ashes must be given. In a fortnight sow Canadian Wonder for succession.

**FORCED VEGETABLES.**—Potatoes in pits or frames now ready for use must have the lights tilted over them continually, as if exposed to heavy rains a secondary growth is liable to take place, this drawing the flavour out of the first tubers. No more water will beneeited at the roots. Later plantings coming on under frame protection must be well nourished to secure normal-sized tubers. In showery weather, if warm, remove the lights entirely by day, replacing them again at eventide. This saves a deal of labour, and is of more benefit than all artificial waterings. Peas now podding in frames will be benefited first by a sprinkling of artificial manure, and afterwards by a mulch of spent Mushroom manure. The same may be said of Carrots.

**SHALLOTS.**—Rows of these now in active growth must be examined, as frequently worms throw the bulbs clean out of the ground, especially on light soils. Replace the bulbs and firmly tread the soil, afterwards applying a good mulch of rich manure. Nothing pays better for good cultivation than Shallots. J. CRAWFORD.

### FRUIT HOUSES.

**FRUITING PINES.**—The favourable weather during the latter part of April will have brought forward the fruiting plants rapidly, and with plenty of sunshine the forward Queens will be swelling freely, and a few fruits colouring. Moisture at the roots and manure may be given liberally, few manures being equal to guano given in water a little warmer than the bottom heat temperature, using rain water when it can be obtained, and the guano well mixed. Guano may with advantage be mixed with water and placed in the evaporating pans, as this will assist swelling. Temperatures may now range from 75° to 80° during the day, giving air when the maximum is reached and closing early in the afternoon to allow the thermometer to run up to 90° or 95°. With mild nights the house may be kept at 75°, with 5° less in cold, windy weather. To maintain a healthy growth, the house should be freely syringed, the walls, floors, and paths being kept moist, but avoid too much moisture over the plants, especially in dull weather. The bottom heat for fruiting plants should not fall below 85°, and though it is well to utilise the sun-heat as much as possible, if the bottom heat is checked the fruits will not finish well. Plants of Smooth Cayenne, Rothschild, and other late kinds for fruiting in the autumn, and which are failing to show fruit, should be kept drier at the roots. The cultural notes advised above for Queens do not apply to these plants, as if allowed to grow too freely a check may be necessary for a short time. If kept drier at the roots and cooler for a few weeks fruit will soon show, but extremes must be avoided. Plants of the late kinds named showing fruit should get liberal treatment as advised for Queens, and as soon as the fruits show colour give more moisture and a growing temperature, removing the plants into their fruiting quarters, as it is not well to retard them when the plants are showing freely. Early plants with fruits colouring should have less moisture and food as the final stage is reached. If the suckers at the base of fruiting plants are numerous, it is well to thin freely; this assists the fruit, and the suckers left make much better material for potting up later on.

**SUCCESSION PLANTS.**—These will now need liberal treatment, and if potted-up as previously advised, the plants will now be making a sturdy top growth and will have made new roots freely. Night temperatures may now range from 65° to 70°, the maximum in mild weather, and 10° higher by day in favourable weather, 75° being high enough if the weather be wet or sunless. High temperatures or excess of moisture will cause a weak growth. A free circulation of air during the day will promote the short leaf growth so desirable. Damp over all parts of the house at closing time, the plants being lightly dewed overhead. Manure water should not be given till the newly-potted plants have filled their pots with roots, but a genial atmosphere may be maintained

by the use of liquid manure in the evaporating pans. With the houses large or much exposed, shading the plants will soon be necessary. It is well to use a temporary shade, as the plants suffer when much shaded in dull weather. Serimeenvas or tiffany on a roller answers well, as this is so readily removed, and it is only required during the hottest part of the day. Some of last year's plants may not have required repotting when the plants were overhauled in March, but these should now receive a shift, as during the winter the soil becomes sour if not full of roots. The materials previously advised will still do; water sparingly for a time, giving the newly-potted plants a genial bottom heat, and shade till well established. Small plants during the summer months are often grown in frames, and they thrive well in such structures if there is a bottom heat of 70 or 80°. Excess of moisture in frames must be guarded against, as the temperature fluctuates more in frames, little water being required in damp weather. With the early Queens ripening there will be some good strong suckers for potting up, and to make room for these some of the strongest plants may be placed in a warmer house. Thus treated there will be a good succession, and in private gardens this is preferred to a glut at one time. The temperature for what may be termed the small plants should be 65 to 70° by day, according to the weather.

**MELONS—EARLY FRUITS.**—On pot plants, or those in restricted borders, the fruit will now be colouring, and need careful treatment to get flavour. During the final swelling it is well to feed liberally, but this must cease when the fruits are well netted. It will soon be seen when growth is complete by the way the fruits net, and if given too much moisture they soon crack badly. The weather now is most favourable for the growth of these plants, and during the day very little fire-heat will be necessary; but it is well to keep the pipes warm during the day, as this allows of freely airing the plants—a great aid to flavour. Later plants need less air and plenty of warmth, a temperature of 70° by night and 10° higher by day, allowing the temperature to run up to 90° at closing time. Syringe freely all parts of the house. Top-dressings with richer soil will also be necessary, but the stems of the plants must be kept clear at the collar to prevent damping. Make the new material firm, keep the stems as dry as possible when syringing, and water frequently with liquid manure as growth increases. Should canker appear, as it often does after a spell of sunless weather, dress the affected parts with freshly slaked lime and powdered charcoal, keeping the plants drier for a few days, and admitting more air.

**MELONS IN PITS.**—At this season preparations may be made to plant in pits or frames, and though the best results may be obtained from heated pits, with care excellent Melons may be grown in cold frames, or even movable ones, on a bed of hot manure. Bottom heat in any case is desirable, but not a necessity. I have grown good-flavoured fruits on a hard, coal-ash bottom, with a barrow-load of soil for the plants, placing a couple of plants in each light; but more care and less moisture are necessary. The start must be with sturdy clean plants raised in houses or warm frames close to the glass and planted out of the seed-pot, making the soil firm round the roots. For frame culture I do not advise the poor soil often recommended, as without heat, growth is none too robust, and quick growth is essential to get fruit of good quality. Loam mixed with bone-meal will be a good compost, and should the soil be far away from the sashes, it is an easy matter to make a trellis and train the plants close to the glass. Melons planted on manure beds often fail to set owing to their gross growth, the roots going down into the rich food. To prevent that, it is a good plan when making the bed to insert a large pot on slates or tiles, which will prevent deep rooting and cause short-jointed wood, earlier setting, and better finish. Good will be done if only flat slates are placed under the plants before adding the soil to prevent the roots striking down-

wards. The temperature in pits varies, but much may be done to maintain an equable one by covering the glass at night, shutting up early in the afternoon, and keeping the lateral growth thin. Moisture should be freely given in fine weather, but early, to allow the plants to dry by sunset. When damping down, thoroughly moisten the surface soil, as the sudden changes of temperature encourage green-fly; whereas a moist soil and surroundings are not congenial to it. Allow each plant to go a fair distance before stopping, but stop lateral growth at the second joint and set the first blooms if possible.

**ORCHARD HOUSE.**—If at all forced, the fruits in this house will be swelling freely, and will require unlimited supplies of water and food also if the pots are full of roots. It is a good plan at this season to liberally top-dress plants heavily laden with fruit or foliage, this being a great saving of labour, whilst the roots benefit greatly. Plants approaching the ripening stage must only get pure water, as food now will spoil the quality of the fruit, and in damping overhead use rain water or water free of lime, as the fruits soon show lime deposits. More air and less atmospheric moisture must be given as the fruits colour, and the leaves when covering the fruit should be removed or the shoots given a tie to allow the light to reach the fruit. Later trees in mixed houses will need copious supplies of water and liquid manure, syringing freely and airing early in the day. In case red spider or fly should appear, fumigate several nights in succession, syringing freely the next morning. Thin fruits severely when needed, pay daily attention to stopping, and with ample supplies of food there will be no fear of the fruits dropping after this date.

G. WYTHES.

## GARDEN SKETCHES.

### CHAPTER XI.

Only so far as the masters of the world  
Have called in Nature to their need  
Can they reach the height of magnificence.  
EMERSON.

**OCTOBER 7.**—Chill October is with us, but there is neither chill nor damp. A second drought has fallen on the garden, and week after week of sunshine without moisture has left the ground dry as dust, and the plants parched and many of them drooping, but let us for a moment look away from the suffering plants and raise our eyes to the glory that has flowed over the valley before us. In amber, crimson, and gold the trees are clad. If cloudless skies have made the blossoms fewer, the trees have been touched to richer hue, and the scattered woodlands pass in undulating lines of colour as far as the eye can see. To-day the hills in shadow are blue as indigo, only the bold projections are soft grey, with here and there a flush that one knows must be the red-brown Braeken. In the garden one can quickly single out the sun worshippers. *Cytisus racemosus* in freshest green is coming into blossom. *Berberis Darwini* has sprays covered with a second bloom. Some plants of *Salvia*, only a few inches high when planted out of doors, have grown into large bushes, with their pink flowering branches tumbling about on every side. *Hypericum Moserianum*, also planted in spring, has grown well, and is now covered with blossoms. The thick substance of the petals makes them look like solid gold, while the stamens rise like a coloured crown in the centre of the blossom. It is indeed a gem among *Hypericums*. Several beds of *East Lothian Stock* planted out in June have, to my disappointment, commenced to flower now instead of waiting for the early days of spring. *Wallflowers* are dwarf and sturdy, so they are safe not to blossom until the new year.

The fountain garden has suffered especially from want of rain, as the wide-branched *Syc-*

more tree sucks up the moisture all around. The scarlet *Geraniums* are the only perfectly happy plants at present. They have never been so splendid, with trusses some 7 inches across and deep green healthy foliage. All the needed cuttings were taken from them a month ago, so that the fine fresh growth has all been made under a burning sun and in ground parched hard and dry. The *Verbenas* seem likewise to revel in the dry heat, and are a mass of blossom. The *Pyrethrums* are fresh and healthy, and coming into a second bloom. *Carnations* have thriven well; the fresh soil appears to have restored them, and they do not seem to have suffered in any way from want of moisture. On the other hand, the bed of *Lobelia fulgens* is pitiful to see, with drooping and yellow leaves, and the white *Chrysanthemums* in the centre are poor and shrivelled. The yellow bed of *J. Wernig Chrysanthemum*, *Rudbeckia Newmanii*, and *Calceolaria amplexicaulis* is worst of all, being nearly burnt up. The loss of this sulphur-yellow *Calceolaria* makes quite a blank in the little garden. Its blossoms were especially bright and cheerful in autumn days, lasting fresh until the first severe frost, and its growth free and graceful. This *Calceolaria* is a native of Peru, from whence it was introduced in the year 1845, and was much prized before the formal bedding-out system pushed it aside as too irregular in growth. The crimson *Fuchsias* are poor and stunted in leaf and blossom, and the pink *Hepaticas* that border the bed are not distinguishable from the ground itself. The leafage of the *Hellebores* has been greatly injured; at least one half of the leaves has been turned brown, and must now be cut off, being too unsightly. It is just one of those rough bits in the path of "gardening" that one cannot tread across without aching feet. The flowers ask, and we cannot give. They suffer, and we are powerless to help, for the water supply has run short for human beings, and so must be denied to plant life.

**OCTOBER 23.**—Russet leaves beneath our feet, crisp and dry and crumpling as we pass along, tell us that the leafy banners have fallen. But they have still their mission to fulfil. Gathered and stored together until they decay, they become most valuable as a quickening, revivifying force to plant life, and though for the moment crushed under our passing tread, they shall live again and wave above us. The autumn leaf-collecting is very important, and being the natural manurial stimulant for plants, is the most fitted for many choice flowers. A pit into which they can be thrown as gathered hastens their decay, keeping them damp when rain falls, and the whole heap can be turned over in spring, which will still further assist in their decay.

Some showers have at last visited us, so that the earth's surface at least is damped, and verdure is returning to the lawn where a few *Daisies* have ventured to uplift their heads. The *Star-worts*, with all their soft shades of purple, lilac, lavender, and dusky blue set among the gold and russet hues of changing leaves, are an October garden in themselves, but this autumn they are very poor compared with other seasons. Sun they must have overhead, but moisture at the root they seem to demand equally, their mass of fibrous rootlets exhausting the surrounding ground very rapidly.

The *Arum Lilies* have just been lifted. They were planted out in the garden in rich soil during the month of June. Fresh fibrous loam mixed with some leaf-mould and a little peat has been used to repot them in. Last year I added some old manure, but found that their leaves constantly turned

yellow. When in full growth, manure water and soot water may be used with advantage. These Lilies of the Nile, growing naturally in water, must be always well supplied with it. Planted in a pond they will live out of doors all winter, although in the open ground they will not survive unless in very favoured localities. The Daturas, which were likewise planted out during summer, have also just been potted. Though killed to the ground by winter frosts, they will spring up again from the roots, but these young shoots are so long in coming into blossom, that I find it better to lift the plants and keep them in the greenhouse during winter, so that they will come quickly into flower when planted out in summer. *Sparmannia africana*, sunk in a pot, is still in blossom in the rock garden, but will be brought indoors on the first appearance of frost.

The beauty of the Begonias being over, they have been taken up and stored away in a box filled with the soil in which they were growing. Their stems will gradually wither away, and then they can be packed in sand, neither too dry nor too moist, and placed out of the reach of frost.

Now is the time to look around and note any alteration to be made, or plants to be divided or removed. While the ground is yet warm, plants root quickly in their new quarters and have time to become established before the frost of winter. The end of September is generally the best season for planting, but this year it was at that time too hot and dry.

Flowers for cutting are at present so scarce because of the drought, that one is glad to see leaves and berries for indoor decoration. The wild Rose hedges from the hedges, with the tinted foliage of Bramble sprays, make a fine group, and the fading leaves of Strawberries, as they change to crimson, afford a rich setting for the white *Chrysanthemum* Daisies. In the arrangement of flowers how often do we see them overcrowded to such a degree, that all their distinctive character and beauty of line and curve are lost. In arranging flowers the chief thing is simplicity and freedom, combined with balance and harmony. In Nature, symmetry is rarely or ever met with, but everywhere, whether it be in the lines of a mountain or in the curved petals of a Lily, harmony and proportion are to be found. In using the word "flower" we are apt to think only of the blossom itself, but in floral compositions the word ought to be understood in its wider sense of the flower-clad stems of plants, or flowering branches of trees. We must remember that each plant has its own special message of beauty to deliver, and if we over-fill our vases this message is lost, or never uttered, in the intricacy of overcrowding. If one takes away from a flower the elegance of its stem and fine curvature of its leafage, we rob it of half its beauty, for the flowers, as we have learnt from Ruskin, are but "the leaves in bridal array." Therefore, in arranging flowers, we should be so sensitive to the delicate display of their exquisite proportions, that such a thing as cutting their stalks all the same length to make them look even, or filling in blossoms to prevent a vacant space, would be impossible. Flowers should always be cut with a length of stem sufficient to show the habit of growth, and a few such sprays placed in a jar or simple glass vessel will have a far more attractive effect in a room than many times the amount of flowers with short stalks all crowded together. Blossoms should, if possible, always be associated with their own foliage. For instance, a vase full of Carnations mixed with their own blue grass is twice as beautiful as when the leaves of any other plant are sub-

stituted. A group of blossoms of one kind, such as Roses in an old china bowl or Lilies in a vase, are always delightful, but two or even three different kinds will assort well together. After that a greater mixture loses its power, and takes away from the sense of repose which true beauty always suggests. The simpler the form of the flower glass the better, and plain glass is best of all, because of the reflected lights and shadows which the flower-stems afford in clear water. Large pottery jars of excellent form can now be procured at little cost, and these may be decorated at home with some Greek tracery or other design in black, or they can be painted black and the design left in the original colour of the jar by stencilling. These jars with a vessel full of water placed inside are admirable where a large display of flowers is desired, as they allow scope for length of branches. It is not, of course, everyone who can find flowers just suited for these large jars, but those who possess old gardens will generally have wherewith to compose beautiful floral pictures. Nothing I have found more lovely in them than branches of Apple blossom cut some 4 feet or 5 feet long, and it will not really harm an old Apple tree now and again to thin out of it a long flowering spray. If we have not Apple trees, branches of the Black Thorn with their white blossoms can perhaps be cut from a country hedgerow or wild bank in some springtide ramble. While yet earlier in the season, branches of the Willow can be found with silvery catkins so lovely, that no painter's brush can ever tell their story.

There is no doubt much of "fashion" in the decorative use of flowers, but we must ever remember that above all fashion reign in immutable calm, the everlasting laws of colour, of harmony, and of form, and if we will only think for ourselves, if we will only be fearless, and not have and do things because others have and do them, but instead choose and seek and do, because of beauty and of fitness, then our gardens and our houses will be a delight and interest to others as well as to ourselves, since they will express our own individuality, that *ego* with which we are all endowed, and that makes us distinctive from each of our fellow-beings, and which, as a divine gift, it should be our endeavour to develop to the utmost.

L. A. L.

(To be continued.)

## THE ROCK GARDEN.

### VI.

APRIL 23.—Copious rain after genial sunshine during the past week has stimulated the growth of all alpine plants, and rock gardens everywhere are donning their best spring garb. I have noticed a large number of rock plants expanding their blossoms during the past week not only here, but in various parts of this county (Devon). The time of blooming is a most important matter, especially for those selecting the material wherewith their rock gardens are to be embellished. We may furnish our rock gardens with many choice and rare plants, and yet we may not be successful in forming a pleasing picture, because flowers which are open at the same time are kept too far apart to form a harmonious combination. With the desire of assisting others, I will, therefore, mention the best of such rock plants as were and are blooming together during the past and the present week (third and fourth week in April) as far as such plants have come under my own observation. Most of the plants mentioned are growing here in Exeter, others at Barnstaple (North Devon),

and some at Newton Abbot and Torquay (South Devon).

### FIT COMPANIONS BLOOMING SIMULTANEOUSLY.

A SELECT CORNER.—*Androsace pyrenaica*, *A. Laggeri*, *A. carnea*, *A. Chumbyi*, *A. Chamaejasme*, *A. arachnoidea*, *A. villosa*. All these gems are now in bloom here and might well be grouped together in the rock garden. They certainly deserve a select corner to themselves, and mostly on a rock so raised as to be near the eye, for otherwise much of their charm would be lost. *Androsace pyrenaica*, for instance, is not a plant for distant effect, but requires the closest observation to be fully appreciated. The tiny white flowers are perhaps less than a quarter of an inch in diameter, and nestle on a compact cushion of diminutive leaves. It grows slowly, but is most desirable. I find it succeeds best in a sloping position and in very stony soil. *Androsace Laggeri* with its pretty pink flowers does best on the half shady side; its moss-like growth is very pretty even when not in bloom. The white-flowering *Androsace villosa* should be planted sideways in a vertical fissure on the sunny side. The rare *Androsace arachnoidea*, which is also now in bloom, requires a similar position. It resembles *A. villosa*, but has larger flowers and is more hairy than the former. *Androsace Chamaejasme*, which also has white flowers, does very well on less sloping ground if well surrounded by small broken stones. *Androsace Chumbyi* requires a sunny position, where it can grow downwards and hang over the stones. It resembles *A. sarmentosa*, but is of slower growth and its flowers are a deep rosy purple instead of pale mauve. It is also earlier in bloom than *A. sarmentosa*, which latter is scarcely showing its buds as yet. *Androsace carnea* I mentioned in my notes of last week, but it is still looking gay with its pink blossoms, and might well be associated with the other kinds just mentioned.

PRIMULAS are blooming abundantly this week. In North Devon I noticed the rosy purple *Primula viscosa* doing well in a sloping position on a half shady rock; also the pure white *P. nivalis* and the bright crimson *P. rosea*. The latter looks most effective in masses, and should always be planted in very moist ground fully exposed to the sun. *Primula platy petala* is a double and very bright purple form of *P. acaulis*. It has here for several years past occupied a shady position, and flowers well every year. *Primula farinosa* (also now in bloom) prefers a moist and sunny position. Other *Primulas* flowering this week in a half-shady position are the bright golden yellow *Primula Auricula*, the purple *P. marginata*, *P. calycina*, with rosy purple flowers, and *P. integrifolia*, which with its glossy leaves and bright purple blossoms is very striking. *Primula Sieboldi* does well here; it was planted in a shady position some two years ago, but seeded itself on the sunny side of the rock, where a fine batch is now in full bloom, while the plants on the shady side are less advanced.

SAXIFRAGES.—The earliest kinds, such as *Saxifraga oppositifolia*, *S. apiculata*, and *S. sancta*, are now past; but that little gem *S. Boydii* is still in bloom. One of the choicest kinds which has opened this week is the true form of *Saxifraga luteo-viridis* (Schott. et Kot.), with its deep yellow corolla almost enclosed in a greenish cup-like calyx. This should be planted sideways into an upright fissure exposed to the sun. *Saxifraga Rochelliana*, with its small silvery rosettes and corymbs of white flowers, is now at its best, and deserves a good place. Two very neat plants of the mossy sec-

tion are also in bloom, viz., the delicate pink *S. Rhei* and the deeper coloured *S. atropurpurea*. Larger kinds with white flowers now blooming on a sunny slope are *S. muscoides* and *S. aromatica*.

SHADE-LOVING PLANTS NOW IN BLOOM.

Dog's-tooth Violets with their rosy flowers and large spotted leaves are a special attraction. In a rock garden in a southern part of this county I noticed a particularly fine form called Alexander von Humboldt with bright pink flowers larger than usual. In the rougher portion and beneath the shade of trees the bright yellow *Epimedium pinnatum* and the pink *Epimedium roseum* are looking well. Anemones of the *A. nemorosa* type are also in bloom, most conspicuous amongst them being the charming blue *Anemone Robinsoniana*. Delightful plants now blooming at Exeter in a prominent but shady position are *Rhodothamnus Chamæcistus*, scarcely 3 inches high, with trusses of large pink flowers, and the American *Houstonia serpyllifolia*, with deep blue flowers, very distinct and far superior to the paler blue *Houstonia cœrulea*. The white form (*Houstonia cœrulea alba*) is also now in bloom. The *Houstonias* require a moist, spongy soil, and succeed well in the shade of a rock.

A SUNNY CORNER.

*Draba aizoides* and *D. Aizoon* are past, but the distinct and pretty *Draba brunneifolia* is still in bloom; it forms a mossy carpet which sets off the bright golden yellow flowers to great advantage. *Gentiana Clusii* has opened its large deep blue flowers, and *Gentiana verna*, in a rather dry, sunny position, is nearly past, but in a moister place on the same rockwork the buds look stronger and are only just beginning to open. *Euphorbia capitata* has its bright yellow flowers fully expanded, and is doing well in a sloping position. A similar place has been assigned to *Veronica telephifolia*, which with its pale blue flowers and glaucous foliage is very charming. *Cerastium lanatum villosum* is a very different thing from the common *C. tomentosum*; it grows but slowly and loves a dry position, where its white flowers are now fully expanded. A very handsome plant blooming on an exposed, but level spot is *Romanzoffia sitchensis*; the orbicular deeply-lobed leaves have an almost wax-like appearance, and the white flowers look very attractive. *Ranunculus montanus* is a somewhat larger plant, which does well in ordinary soil at the foot of a rock; it grows about 6 inches high and has large deep yellow flowers.

CARPETING PLANTS IN BLOOM.

The following plants now flowering are too well known to need any further comment. They are best adapted for the rougher part of the rock garden, where by their somewhat rapid growth they could not endanger the smaller and choicer kinds. *Arabis alba*, *A. lucida*, *Aubrietias*, *Schivereckia podolica* (white), *Hutchinsia alpina* (white), *Alyssum saxatile*, *Cardamine trifoliata* (white), and the deep blue *Lithospermum prostratum* are now all in bloom. The last has, unfortunately, suffered severely in most places during the past winter.

MEDIUM-SIZED PLANTS NOW BLOOMING.

The following might well be introduced in prominent places between and at some distance from the rocks reserved for the smaller and choicer kinds: *Dielytra eximia*, *Arnebia echioides*, the well-known Prophet's Flower, *Waldsteinia trifoliata*, *W. fragarioides*, *Caltha palus-*

*tris flore-pleno* (the double Marsh Marigold), *Corydalis ochroleuca*, and *Gemma aureum*. With the exception of *Dielytra* all these are yellow, and in arranging them care should be taken to introduce them between groups of plants whose colours would blend harmoniously.

Exeter.

F. W. MEYER.

(To be continued.)

DAFFODILS AS CUT FLOWERS.

As in the case of other flowers, when there happens to be a profusion of bloom there is in that of the Daffodil also the same danger of overcrowding taking place. Surely no better example of the beautiful is needed than is provided in the natural growth of these pleasing spring flowers, the foliage, in combination with the blossoms, affording an example of what to adopt when arranging the cut blooms. When growing and in flower the foliage and the

blossoms still upon the plant; but invariably the colour is slightly better unless shading is adopted, as in the case of the florist's Tulip. Regarding the use of the foliage, it may be urged that to cut it largely would weaken the bulbs, but it may be taken a leaf here and a leaf there, so as not to make any perceptible difference; or where a good stock of the common Daffodil exists, its foliage can be taken in preference. To mix the different types is not so desirable as that of keeping them separate, nor is it in good taste to mix the single with the double varieties. For instance, *poeticus ornatus*, although so beautiful by itself, is quite out of place with the common Daffodil, or with such as *Emperor* and *Empress*. Use these two latter kinds, however, in combination, and a charming effect is produced. At least four divisions can be made in this direction, each being kept to itself—viz., those with large trumpets, as *Emperor* and *Horsfieldi*; those with medium trumpets, as the *Barri*, *Leedsi* and *incomparabilis* forms;

Daffodils in a vase.

blossom seem to be, as they really are, quite indispensable the one to the other. Let this be imitated, then, as nearly as possible when disposing of the cut blooms, and afterwards, if need be, compare the natural style with the opposite or unnatural by massing the flowers something in the same manner as they are sent to market in bunches, with which it is a rare occurrence for any foliage to be included, much as it is needed. Each flower should be so displayed as not to crowd upon that next to it; it is only in this way that the best possible effect can be had. Oftentimes when cutting Daffodils from home-grown plants there is a danger of two mistakes being made; the one is that of gathering too many sorts at once, and the other that of taking flowers which have been expanded for some time. It is not perhaps generally known that many who exhibit Daffodils in large numbers cut them before they are really fully expanded. Afterwards they continue to develop, but may not possibly reach quite to the size of

those with small trumpets, as the *Burbidgei* and *poeticus* types; and those with small flowers, as *cyclamineus*, the *Hoop-petticoat* *Narcissus* and the *Jonquils*. H. G.

**Forsythia suspensa.**—As a plant for covering walls or for similar purposes this *Forsythia* is well known, but as a bush in the open ground the most generally grown species is *viridissima*, which is, however, not so showy as its more rambling-growing relative. Notwithstanding the fact that *F. suspensa* may be treated as a climber, it is also seen to very great advantage as an open bush, as it forms a pleasing specimen of loose, irregular outline, and the strong arching shoots, which are pushed up so freely, are just now wreathed with beautiful golden blossoms. An isolated specimen will when in a flourishing condition quickly establish quite a colony around it, for not only are suckers pushed up freely, but when the tips of the long shoots come into contact with the earth they soon root, after the manner of a Bramble, and quickly form a good-sized plant.

*F. suspensa* is certainly one of the very finest of all early-flowering shrubs. The late excessively severe winter does not seem to have affected it in any way.—T.

**Prunus divaricata.**—Each recurring season a fine tree of this species is very beautiful at Kew, yet despite its undoubted merit as a lawn tree it is very seldom met with and may be sought for in vain in most nurseries. It forms a very handsome tree with a rather wide-spreading, freely-branched head, and early in the spring when every twig is laden with white blossoms it stands out very conspicuous. *Prunus divaricata* is a native of the Caucasus, and, according to Loudon, was introduced in 1820.—T.

## ORCHARD AND FRUIT GARDEN.

### PEAR WILLIAMS' BON CHRETIEN.

No Pear is better known than this, as it succeeds admirably in many forms of tree, and is not so capricious as to soil and situation as some other sorts, though naturally it is better from favourable aspects and other conditions in its favour. Grand fruits are produced on cordon and wall trees, but, according to my experience, the best flavoured fruit is obtained from bush or pyramid trees, where they will succeed. No doubt the free circulation of air and greater amount of light are the causes of this superior quality; not only so, but the fruit from these trees always keeps longer without decaying at the centre than the larger and more imposing Pears from wall trees. In spite of its early decay I think the variety will always hold its position for private use, as its rich flavour and pleasant perfume will always make it a favourite. Whether it will be as popular a market Pear in the future as in the past is doubtful. Low prices arising from the increased production and glutted markets, uncertain cropping, and the introduction of handsome varieties that surpass it in appearance, are more prolific, and not so liable to blemishes or black spots on the skin as Williams' Bon Chrétien, will cause growers to be very careful about planting more of the variety. I am sorry to see Clapp's Favourite ousting Williams' in many places, as the quality is a long way behind that of the old favourite, and those growers who have made the change claim that Clapp's is not so subject to fungoid and insect attacks. When disfigured fruit and foliage are attributed entirely to those two causes, I think the cultivator should also bear some of the blame, as there are now so many well-proved remedies for such evils that it is certainly some fault on the grower's part if he allows the enemies to practically spoil the crop and foliage, thereby injuring future prospects. I believe the argument that Williams' is more prone to the pests attacking Pears than other varieties will not stand good, as it has never shown any such tendencies with me amongst over a thousand trees in great variety. All the Pear trees are washed alike with an insecticide, which also acts on any fungus, and I would here urge on all who may be using Paris green or other strong remedies to never spray their trees while in bloom, otherwise injury will follow; but immediately the fruit is set it will be safe to spray again. W. G. C.

**Apple Pine-apple Russet.**—I have here one tree of this Apple. It was formerly a bush, but not being able to get any fruit from it, I allowed

it to grow away at will, hardly pruning it at all. One season it made shoots 5 feet long, and I allowed these to remain almost their whole length. For the last ten years I have had fruit every season, but never a heavy crop. There is something about the flavour of this Apple that is most peculiar, yet pleasing, and which most persons who have tasted it appear to like. It is an Apple that I should not care to recommend now that there is such a number of more certain sorts.—E. M.

**Strawberry Noble for forcing.**—By several persons in this neighbourhood, one especially, this Strawberry is thought highly of for forcing. Not only does the fruit set freely, but it grows to a large size and takes on a rich colour. A person of my acquaintance grows a good number of plants, and with good results, I should say, when we consider the price paid per lb. for the fruit—4s. 6d., and for specially selected 5s. The demand is much greater than the supply, even at this price. He commences forcing the plants early in January, and has the fruit ripe by the middle of March. By the same time in April a quantity has been gathered at prices that cannot fail to be remunerative. Instead of layering the runners into pots in the usual way, he layers them in the open ground between the rows of plants, and when they are well established lifts them carefully into the fruiting pots. Thus the labour entailed in watering, as in the case of pots of any size, while the runners are becoming established is saved. Capital plants are evidently obtained, judging from the produce.—E. M.

**Apricots.**—Apricots, I find, are setting freely and promise an abundant crop, but trees on exposed borders will soon require liquid food and early thinning. Many growers, myself included, often fail to thin Apricots when set, leaving them to a later stage, when they have robbed the trees of much energy and are of little value. I have seen it stated that these fruits in a green state are much valued in the kitchen for tarts, but if left too long they are of little value, and it is well to thin early for the sake of the later fruits and to throw all the vigour into the crop. When the trees are well cared for there need be little anxiety as to stoning. A limited number of fruits has a better chance than crowded ones. We get much finer fruit, have less trouble with insect pests, and there is less canker when the trees are well fed and thinning and stopping of the shoots are practised early.—W.

### RASPBERRIES.

It is worthy of note how the different varieties of these have withstood the late winter. On looking over the rows I find that some of the kinds are nearly killed to the ground, while others have scarcely suffered at all. How to account for this was not difficult when we take all things into consideration, but to those who have not hitherto tried the different modes side by side it may be of interest. Last season Superlative made fine strong canes about 8 feet high, and the buds are quite plump from bottom to top. The plants, standing singly about a foot apart, are trained to wires strained across the plot. The rows are 12 feet apart, so that the light and air are able to penetrate both sides of the rows to thoroughly ripen the canes. A row of Prince of Wales growing close by and treated similarly has also withstood the winter well, while several rows planted in clumps, having four or five canes tied to each stake are nearly all killed to the ground. Several rows of Fastolf, Carter's Prolific, Red Antwerp, and some others treated in this way have also suffered, while those of the same kinds planted in single rows and trained to wires do not seem to have suffered in the least. From this it is evident that the canes grown in clumps were not so well ripened as those in the single rows, which had only a space of 6 feet between them. On our soil Raspberry canes grow very strong, many of the more robust kinds reaching from 10 feet to 12 feet in length. These are cut back in spring to 6 feet or

7 feet. During ordinary winters these have withstood the frost and have produced very fine crops of fruit the following season; sometimes, however, they have failed, but I have never noticed it to the same extent as this season. Would it not be better on such ground to plant in single rows and allow a greater distance between them? I have usually gathered more fruit from a row of canes planted in clumps 4 feet apart than from those on the single cane system, but sometimes after a severe winter those grown by the former mode have suffered considerably; therefore, taking all things into consideration, I think the latter plan would be most profitable, as the canes would be more thoroughly matured, and therefore not so liable to get injured during severe winters. That soils and situations have a great influence on the hardiness of plants there can be but little doubt, and those gardens situated in low, wet places where the ground is heavy suffer much more from the effects of frost than others on higher elevations. As an instance of this, recently our thermometer fell to 27° Fahr., while at an elevation of 600 feet four miles away 35° was the lowest recorded, thus showing that though plants may be perfectly hardy on the high ground they will not stand in low, wet places where the soil is retentive.

H. C. PRINSEP.

**The Apple blossom weevil.**—At page 285 Mr. S. T. Wright refers to this terrible pest as being numerous in some districts this season. As a rule we suffer very much from its ravages in this neighbourhood, but I am happy to say that the bloom petals seem to be growing out of its reach. If the spring is tolerably forward the insects are not hatched until the flower trusses are well advanced; consequently the crop is saved; but in backward seasons I have seen well furnished trees divested of every bloom in a short time. The pest, moreover, seems more partial to some varieties than others. Cox's Orange Pippin and Cox's Pomona being special favourites. I think the bloom on small trees can be saved by sprinkling them over on dewy mornings with wood ashes.—J. C.

**Madresfield Court and Gros Colman Grapes.**—The experience of your correspondent, R. Katzer (p. 287), in regard to the cracking of Madresfield Court differs somewhat from my own, inasmuch as with him this malady, while affecting his bunches in the early house, was absent altogether from those in a later house. I have a Vine inarched on to the Muscat of Alexandria stock. This is usually started about the end of November, the fruit ripening early in June. I allow a good deal of atmospheric moisture with air on even until the berries are nearly finished, and yet they never crack. The Vine in a later house, started in February, and which is inarched on the Black Alicante, troubles me somewhat, not by the ordinary cracking, but by the skin giving way where the berries wedge each other. For this reason I now always thin the bunches very freely to avoid pressure. A grower for market once told me that he was at one time much troubled with cracking in this Grape, and that preserving a dry atmosphere did not cure it. At last he took to supplying the roots with double the ordinary quantity of water, when the cracking entirely ceased. I myself think that to withhold root moisture just when the berries are colouring is a great mistake. It is then that the border, if inside, wants a good soaking to enable the berries to swell to their normal size and to lay on a good bloom. In regard to Madresfield Court requiring less heat than the Hamburg, I should be very sorry to plant it in a house with Hamburg that came on without the aid of fire heat. My experience is that it will stand and even enjoy as much heat as Muscat of Alexandria. R. Katzer asks if Gros Colman inarched on to Black Alicante or Muscat would ripen properly in a late house. My answer is, yes. In the case of the splendid Gros Colman grown at Kelham Hall and always ripe in September the Vines are not started until March. These are grafted on the Muscat.—J. CRAWFORD.

## STOVE AND GREENHOUSE.

## THE TUBEROSE.

THIS old inmate of our gardens came originally from Mexico, having been introduced as long back as 1629. Its culture, however, in large quantities for the trade and private uses has only been taken up in the present extensive

*The African Tuberose.*

manner within the past ten or fifteen years. The demand probably never has at any time been greater than it is now. It does not require any great effort of memory to recall the time when the only term given was that of the Italian Tuberose, not from the fact of its being a native of Italy, but by reason of its there finding a congenial home. Since then, and only in recent years, the culture of this flower for exportation has extended to South Africa and to America. On the former continent it is largely grown in the Natal district, where many acres are annually planted. On the latter continent it is largely grown in the Southern States, whilst the West Indian Islands supply their quota also. The variety known as the Pearl is of dwarfer habit, more, I presume, from the treatment accorded or from the climate where it is grown than from any really distinct and fixed characteristic of its own. Without knowing the exact surroundings whereby this is brought about, it may be fairly assumed that it is the climatic influence which causes it during the ripening process of the growth.

By purchasing bulbs grown in the several districts named, it is now possible to greatly extend the season of supply. For instance, the Cape bulbs are ready in September, whereas the American supply is not available until December; by retarding the latter and hastening the former a supply may be kept up under other favourable conditions the year round. When forcing has to be done, bottom-heat is a decided

boon, as in the case of the Lily of the Valley, but later batches do not really stand in need of it. The latest of the American bulbs can be successfully grown by planting them outside on warm borders. These, if planted during May and early in June, can afterwards be lifted and flowered in the late autumn in warmth. Another plan is to plunge them over the rims of the pots where the soil outside is too heavy or too cold. Loam is oftentimes recommended as the soil in which to pot them, but half and half of loam and peat (or leaf-soil if peat be scarce) will give more satisfactory results. No manure is needed in the soil, otherwise it will tend to produce a super-abundant leaf growth, but manure water will, if given after the spikes are fairly started, greatly assist the bulbs in developing the flowers. In private gardens the one great trouble oftentimes is that of red spider, to which the Tuberose seems to be predisposed. This can be kept in check best by frequent syringings, using water impregnated with the properties of soot, but in a clear (or nearly so) state. A moist atmosphere will, of course, be far better as a preventive. In any case it is best to avoid growing the plants in vineries, Peach houses, &c., for this reason. The Tuberose makes one of the prettiest button-hole bouquets imaginable, a good background for two or three flowers and a bud being a spray of the Box-leaved Myrtle. The double is by far the most popular form, but the single is not by any means to be despised, particularly when the flowers are just expanded. The mistake often made is that of giving water too freely before the growths have advanced sufficiently for the pots to be fairly well filled with roots. When the pots are well filled with roots and the spikes pushing up, then manure water may be freely given, that from the farmyard being preferable. Where many suckers appear around the crown growth, it is a good plan to thin them out, otherwise the flower-spike will be weakened. Personally, I have had a preference for growing the Tuberose in the long pots, oftentimes termed Hyacinth pots: these take less room and are quite large enough.

SOUTHROX.

**Anthurium Andreanum album.**—A white-flowered *A. Andreanum* has been referred to more than once, but the flowers that have come under my observation were small and of a pinkish tinge. I recently saw a white-flowered variety with a spathe equal in size to that of an ordinary *A. Andreanum*. The contrast between this *Anthurium* and the brilliant spathes of the others is most marked, and it will doubtless in time be very generally grown. The spathe of this variety is less corrugated than that of the type. Apart from their quaint and showy blossoms, the foliage of this class of *Anthuriums* is decidedly ornamental. The flowers, too, remain fresh for a long time, this being another great point in favour of these Aroids.—H. P.

**Richardia Pentlandi.**—On April 24 some 300 tubers, announced as the "new yellow Arum Lily *Pentlandi*," were offered for sale, and they attracted a sufficient amount of atten-

tion to show that these golden flowered *Callas* are decided favourites at the present time. Single tubers realised from 26s. to 35s. each, while smaller ones sold in pairs fetched 30s. the two. Others were disposed of in fours at about 13s. each. If this consignment turns out to be correctly named we shall soon see this *Calla* more generally grown. In connection with the prices above quoted it may be interesting to recall those realised by *R. Elliottiana* when sold at the same place on June 17, 1892. The highest price for one plant of this was 17 guineas, and the lowest about 14s., but these last were very small. The plants of *R. Elliottiana* were all in a growing state, hence no doubt existed as to their correct name, but those of *R. Pentlandi* sold the other day were quite dormant, and in that state could not be distinguished from others, especially *R. hastata*. On December 14, 1892, a quantity of tubers was disposed of at prices varying from 12s. to 15s. each as *Calla Pride of the Congo*, and announced as a "new golden flowered *Calla* from Africa," but on flowering they (or at all events all that came under my observation) turned out to be *R. hastata*. It is to be hoped that those sold the other day as *R. Pentlandi* will prove to be correct.—H. P.

## SNAKES-HEAD FRITILLARY.

A good garden plant that comes straight from our English meadows is *Fritillaria Meleagris*. In some districts both the purple and the beautiful white variety abound. For simple beauty it holds its own against any of the numerous garden *Fritillaries* of low stature. The curious chequering of the flower is very interesting when observed closely. It is not affected by colouring only, as it is nearly equally perceptible in the pure white. These pretty plants like a cool soil that is never dried up, if among Grass so much the better, water meadows being their

*The Snake's-head (Fritillaria Meleagris) as a pot plant.*

natural home. The illustration shows the beauty of the bulb in a pot, a purpose for which it is well adapted. The bulbs must be potted up in the autumn and in ordinary soil. They will grow freely in a greenhouse.

**Fuchsia Princess May.**—A great many of the new *Fuchsias* sent out within the last few years have been principally remarkable for the size of their flowers, for, in common with many

other subjects, the production of huge blooms seems to be the one object aimed at by the raisers. This, however, cannot be said of the variety Princess May, which is a pretty and remarkably free-flowering Fuchsia even in a small state. This is one of the light-coloured Fuchsias, the tube and sepals being white, with a slight blush tint, while the single corolla is of a pleasing shade of rosy coral. It is of a dwarf, freely-branched habit, just the style of plant that is popular with our market growers, and I hear that some of them think highly of it. This variety does not grow so freely as some, but during its earlier stages it responds readily to a little more heat than most of them need. Princess May was raised by Mr. Banks, who many years ago was well known as a raiser of new Fuchsias.—H. P.

### THE MARKET GARDEN.\*

#### FIELD CULTURE OF VEGETABLES.

THE ways and means which at the present day are open to the cultivator who desires to increase the number and variety of his crops are more numerous and varied than ever, but, at the same time, the number of the crops that will certainly pay has become more and more limited. This is so because the increasing competition of foreign countries is more widely felt, while in the interior districts the constant increase of imposts and charges of all kinds bears more and more heavily upon the expenses of production.

This foreign competition, however, does not extend in the same degree to all the products of agriculture, but the kinds which suffer most from it are those which, from their good keeping properties and their immunity from injury in transit, can be easily sent to our markets from distant foreign countries.

The products which, in a great measure, are free from foreign competition are those which, requiring to be consumed while fresh, cannot bear long journeys without having their selling price considerably diminished thereby, and to this class belong fruits and fresh vegetables. Accordingly, I have thought that it would be highly advantageous to cultivators if someone pointed out to them certain fruits and vegetables which might be admitted into the general plan of farm culture, and which, if properly attended to, would yield a profit not to be despised.

With regard to fruits and fruit trees, that part of the question has been already disposed of, as one of your fellow-townsmen, Mons. Charles Baltet, has supplied instructions and advice of the greatest importance on this subject, and I shall now confine myself to an account of the vegetables which may be profitably introduced into field culture, especially in the proximity of large centres of population, and more particularly of the industrial classes, where there would be a considerable demand for fresh vegetables.

In the first place, it is necessary to make a distinction between those kinds of vegetables which can be almost certainly grown successfully without any artificial watering and those kinds which, on the other hand, almost indisputably require to have a considerable quantity of water supplied to them by means of infiltration, irrigation, or any other method. The language of every-day life, which is always picturesque and logical in its expressions and derivations, has given the name of "culture maraichère" (that is, "cultivation in the marais" or marshes) to that department of cultivation which aims chiefly at the production of fresh vegetables on a large scale and by speedy methods. The earliest specialist cultivators

had in fact recognised the necessity of supplying many kinds of vegetables with a far greater quantity of water than is afforded them by an occasional fall of rain. Hence the establishment of the first market gardens in low-lying, sometimes marshy, parts of Grass lands, where the soil was always moist from its proximity to the underground water, which being always not far from the surface could without any great labour also be utilised for artificial watering. It is for this reason that the culture of vegetables in the neighbourhood of towns is chiefly confined to the valleys and the low-lying, moist parts of the adjacent plains. One of the most interesting examples of this kind of culture is furnished by the "hortillons" (or market gardeners) of Amiens, who raise their crops on the dry-land portions of ancient peat bogs which are traversed by innumerable canals serving for the transport of both products and manure—a veritable Venice of market gardens.

But, although most kinds of vegetables are benefited by being abundantly supplied with water, there are some kinds which, in ordinary seasons, are satisfied with the rain that falls during summer in our climate, and on this distinction is based the agricultural prosperity of many localities around Paris, where without artificial watering and under much the same conditions as those of careful field culture a large proportion of the vegetables which supply the markets of Paris is raised. Around nearly the whole of Paris extends a zone varying in width from eight to twenty-four miles in which the farmers devote sometimes a very considerable proportion of their land to the production of vegetables which they usually bring to the city market themselves with their own carts and horses, so that the limit of these cultivators is mostly fixed by the distance to which a horse can go and return in a night and half a day.

In the neighbourhood of Verrières, for example (which I know particularly well from having spent about half of every year there all my life), eight miles from Paris, about one-fourth of the soil is devoted to the culture of crops for the Paris markets. There one may see numerous orchards of low-trained fruit trees and plantations of Currants and Gooseberries, not to speak of very many choice kinds of Cherries and Plums. All these, however, come into the list of the subjects of which Mons. Charles Baltet has treated so well. But amongst these plantations, or under the trees, large areas of ground are covered with Strawberries, dwarf Peas, and even Violets. In the most open parts Asparagus and early Potatoes are grown for the first spring crops, also Haricot Beans for cooking green, early tall-growing Peas, Gherkins, Spinach, Sorrel, Brussels Sprouts, and, for some time past, even Cauliflowers and Tomatoes. All these are grown without any artificial watering, and I think they form a pretty exact list of the vegetables which can be recommended for field culture in localities where the climate is similar to that of Paris.

In this discourse, therefore, I shall more particularly treat of the culture of Asparagus, Gherkins, Spinach, Haricot Beans, Peas and Potatoes, not forgetting, however, those other kinds of vegetables which, being more exacting in the matter of moisture, may find in valley lands a position favourable to their growth, viz., Artichokes, Cardoons, Celery, various salad plants and most of the kitchen garden roots. In short, I shall divide this culture of vegetables on a large scale into two sections: (1) the culture of the more hardy kinds in plains and upland districts, and (2) the culture in valleys of those kinds which require a more abundant supply of moisture.

This division, I admit, cannot always be strictly maintained, as it is liable to be influenced by many local peculiarities: but it is founded, as I believe, on a sound basis, namely, the difference or distinction that must be made between ground which receives only the rain water that falls upon it, and other ground, such as that in valleys, which receives, through infiltration, a portion of the rain water that falls upon the higher ground.

As it would take several hours to exhaust this subject even in its simplest aspect, and as the time at my disposal is limited, my observations will bear chiefly upon the selection of the most suitable varieties of each kind of vegetable for field culture, together with a description of their distinctive characteristics. The more indeed the adaptabilities of plants are specialised, the more important to the success of the planting is the selection of a variety which is well adapted for the object which one has in view.

(1) *The hardiest kinds of vegetables which, not requiring any artificial watering, are most suitable for cultivation in ordinary flat or upland districts.*

#### ASPARAGUS.

The field culture of Asparagus is one of the most interesting innovations of the present age, and one which has been attended with the most striking success. At almost all times a few rows of Asparagus plants have been interspersed amongst other crops, and notably amongst Vines. It was in this way that the culture of Asparagus commenced at Argenteuil, but owing to the proximity of Paris and the enterprising spirit of the cultivators, that which at first was a mere accessory very soon became the chief object of attention, and the profit which the people of Argenteuil now derive from their crops of Asparagus undoubtedly exceeds that which they obtain from their vineyards. There is no other crop, perhaps, which yields so large a return for the care bestowed upon it as Asparagus. One might say that, as is the case with diamonds, the value of Asparagus increases in proportion to the square of the size of the plants, so that a bundle of it which has cost twice as much to produce it as another bundle has will readily sell for four times the price of the latter.

In plains or flat districts any kind of good soil, provided it is well drained, is suitable for the cultivation of Asparagus; at the same time there is a great advantage in selecting ground that is mellow, light and easily worked, as with soil of this kind the numerous operations connected with the maintenance, earthing-up, manuring and cutting of the crop are much less expensive, and are done in a better and more satisfactory manner.

There are numerous instances of plantations of Asparagus which are 25 acres or even 50 acres in extent, and are cultivated entirely with the plough, with the exception of the manual labour which is always required in the operations of earthing up the plants and gathering the crop. Manure should be liberally supplied. The heads of the Asparagus grown at Argenteuil are indebted for their size and fine appearance to plentiful applications of the night soil which is carted from Paris. A small quantity of sea salt, of which a special preparation is sold for agricultural purposes, is a useful addition to the manure.

With respect to the best varieties, the preference should be given to the Argenteuil early and late kinds (Asperge hâtive and A. tardive d'Argenteuil). These two kinds should be grown in every plantation in the proportion of three-fourths of the early variety to one-fourth

\* Address delivered by Mons. Henri de Vilmorin at the Congrès Agricole de Troyes, June 4, 1892.

of the late. The difference between them is not so much with respect to the time at which the shoots become fit for cutting as that the late variety continues to produce very fine heads for a much longer period than the early kind, which in the beginning of the season yields very fine heads, but these soon decrease very much in size, although abundantly produced. It is then that the late kind comes in, happily, with its good-sized heads, which are all the more valuable from their comparative rareness at that season. These large-sized heads are used either for setting off bundles of small-sized Asparagus or are made by themselves into choice bundles, which at the end of the season command almost as high prices as they did at the beginning.

Amongst the general considerations which are favourable to the field culture of Asparagus may be reckoned (1) the increasing demand for this vegetable, which keeps up the market price of it, notwithstanding its more extensive cultivation; (2) the great length of time which plantations of Asparagus will last when they are once well established; (3) the possibility of rendering the plantations exceptionally productive by setting the plants well apart from one another, so that they may produce heads of increased size by the careful preparation of the ground and by a judicious use of manures; (4) the comparatively high value of the produce, which insures the cultivator against any risk of loss in sending it, even great distances, to markets where the local Asparagus crop has not yet come in or where the supply has ceased.

#### BORECOLE AND BRUSSELS SPROUTS.

Many varieties of hearting or solid-headed Cabbages may be grown in fields in ordinary soil and without any artificial watering, but crops of these kinds of Cabbage are always more or less precarious, the occurrence of unusually hot and dry weather in spring being very detrimental to their growth. Of this class, therefore, I can only recommend with confidence—for field culture in ordinary flat districts—the autumn kinds which do not form heads until the beginning of winter, and even then sometimes do so rather imperfectly. The best of these is the Chou de Vaugirard, which is so highly esteemed in the neighbourhood of Paris, and the Chou de Milan court hâtif, which, when sown in June or July and planted out when the autumn showers begin to fall, yields throughout the winter broad rosettes of very early and very tender leaves surrounding a heart which is generally about the size of two fists at the most.

The small Chou frisé de Limay, which is almost the same variety as the last-mentioned, but bearing the head on a tall instead of a very dwarf stem, is also suitable for field culture. These three kinds possess the double advantage of thoroughly withstanding frosty weather and of continuing fit for use for a long time, so that the grower can wait, without any risk of loss, for market days when the price will be a paying one, and also for such times as will bring weather favourable for cutting the crop and sending it to market. Forming imperfect heads, these varieties bring us, by a very natural transition, to the Borecoles, which do not form any head at all and which are not much grown in France, notwithstanding their great utility as a winter vegetable. Fully a dozen varieties of Borecole are grown in England and in Germany, but in France we grow hardly any except the green and purple curled kinds, tall and dwarf. The Borecoles are perfectly hardy plants, having withstood the frosts of the terrible winters of 1879 and 1890 uninjured, and produce leaves which are very palatable and even delicate in

flavour, especially after frost has acted upon them. Besides these common and very hardy kinds, the Chou frisé de Mosbach, the variety known as Bricoli at the Halle market in Paris, and the common and curled varieties of the Couve Tronchuda, or Portugal Cabbage, are also very suitable for field culture.

The same can be said of the Brussels Sprouts, which do not commence to bear until October or November, and which, having been planted out when the spring-sown plants are strong enough, will yield a plentiful succession of sprouts all through the winter. This vegetable is coming more and more into request in our markets, and the following three varieties are those which are most in favour at Paris:—

1. CHOU DE BRUXELLES GRAND, a very productive kind, bearing a great number of sprouts about the size of a large Hazel nut.

2. CHOU DE BRUXELLES NAIN, a dwarf-growing and more thick-set kind, bearing much larger sprouts (as large as a Walnut). Large-sized Brussels Sprouts are thought much of in England and are admired at exhibitions, but are inferior to the small-sized kinds in delicacy of flavour.

3. CHOU DE BRUXELLES MOYEN DE LA HALLE is the acme of production achieved by the cultivators who supply Paris. The plants of this variety are very regular in growth, and are characterised by the purplish tint of the leaf-stalks. The sprouts are round, nearly spherical in shape, well formed, furnishing the stem regularly, and are produced in succession for three or four months. The variety is also hardy and quite suitable for field culture. In gathering all kinds of Brussels Sprouts a good deal of hand labour is required.

(To be continued.)

### NOTES OF THE WEEK.

*Incarvillea alpina* (?) has stood the winter unprotected in the open. At present there is some question as to how far this is synonymous with *I. Delavayi*, as this latter does not seem to have flowered in England.—W. THOMPSON, Ipswich.

*Spiræa Thunbergi* fl. pl.—Almost all good shrubs find a congenial home at Syon House, and in the rich soil grow and show themselves in their prettiest aspects. This one is delightful, tall, its slender shoots perfect wreaths of pure white double flowers.

*Trillium grandiflorum* in a moist nook of the rock garden at Kew is one of the finest things in flower in the present week. A large tuft has nearly forty fine flowers all open. Anyone with a place likely to suit this the finest of all the Wood Lilies should try and grow it.

*Iris cæspitosa* is a pretty kind now in bloom. It has thick tufts of narrow, grassy leaves, and out of flower might be taken for a strong plant of the Cock's-foot Grass. Its flowers, which are freely borne, are of a deep violet-blue colour and carried on short stems which do not rise above the leaves.

*Phlox canadensis*.—The alpine Phloxes are among the brightest of spring flowers for the rock garden, and make fine sheets of colour. This species now flowering at Kew is most distinct and very pretty, the flowers in shape and disposition resembling those of *P. reptans*, but of a lovely pale blue shade.

The single Jew's Mallow.—The merits of this flowering shrub are not sufficiently recognised, but it has a distinct and graceful beauty of its own and is like a single yellow Rose in effect. A large group of it is quite the best thing among shrubs in the present week, the bushes being covered with flowers.

*Pyrus spectabilis* is a picture of soft pink on the mound at Kew, and in common with all its kindred is flowering with unusual freedom. We

trust these noble flowering trees may some day become more common in gardens. At present it is quite the exception to see them, and yet visitors to Kew pause to note the beauty of this and similar trees.

*Sairtpaulia ionantha*.—This pretty plant, of which a coloured plate was given in THE GARDEN for February 23 of this year, is well grown by Mr. Laing at Forest Hill, and when there recently we saw several healthy specimens in abundant bloom. The colour of its flowers is rich and effective, and doubtless the plant will soon become popular.

*Magnolia Soulangeana*.—This Magnolia is now flowering finely at Syon House, where both it and *M. conspicua* are well represented by large specimens. Its deep purple-stained flowers are rich in effect, and besides its distinctness of colour it is valuable, as it flowers from a week to ten days later than *M. conspicua*, thus prolonging the blooming season of these noble-flowering trees.

*Cytisus præcox*.—Groups of this pretty and early-flowering Broom are now very bright at Kew. It is a shrub of great beauty, strangely much neglected in gardens. Whilst many of the better-known Brooms, such as the white Portuguese and the yellow Spanish, are seriously crippled, this kind is flowering with its usual freedom, showing no traces of the severe cold.

*Ranunculus aconitifolius* is best known in its double-flowered form, but the type itself is well worth growing by those who have a moist place such as it wants. It luxuriates at Kew, with its roots perpetually moistened by the tiny stream that flows through the bog, and at the present time its leafy tufts are thickly studded with the single white flowers.

*Cœlogyne pandurata*.—I have a nice spike of this Orchid just opening. The spike is 2 feet 6 inches long and has thirteen blooms, each 5 inches in diameter. The sepals and petals are of a lovely soft shade of green, the lip jet-black and beautifully fringed. The spike has a bold, pleasing appearance.—F. KNIGHTS, Bitteswell Hall Gardens, Lutterworth, Leicestershire.

*Tulipa linifolia* and *T. montana* are two of the smaller species now in flower at Kew, but both bright and distinct. *T. linifolia* has long narrow grassy leaves, the flowers pale red externally, brighter scarlet inside, with a shining black base. *T. montana* has undulated leaves and a bright red flower with a regular zone of black, faintly margined with yellow at the base inside.

*Iris pumila*.—This is one of the dwarfiest of the Flag Irises, and a useful plant on light, free soils near the edge of beds and borders. It spreads about and quite early in spring becomes a sheet of flowers. There are several different coloured forms of it. One of the best which we noted recently at Long Ditton is Count Andrassy, with flowers of a deep blue shade, very freely produced.

*Polemonium humile* is a small, but pretty species, well worthy of the little care necessary to bring it safely through the winter. It perishes on cold or wet soils, but is hardy in those that are warm and well drained. We noticed it in flower the other day at Messrs. Laing and Sons, Forest Hill. Its leaves are much smaller than those of *P. œruleum*, but the flowers are large, pale blue, and borne on stems 6 inches to 8 inches high.

Strawberry Laxton's Leader.—Messrs. Laxton send us fruits of a fine new Strawberry named Leader, the result of a cross between Latest of All and Noble. The fruits are conical, in some cases wedge-shaped, the colour bright crimson, flesh scarlet throughout, and with a sharp, piquant flavour. It seems to be a variety that will travel well. The plants from which the fruits were gathered were only potted up at the end of September.

*Tulipa Haageri* and *T. Sprengeri* are two pretty Tulips now in flower at Kew. Though distinct from a garden point of view, *T. Sprengeri* will probably be classed only as a variety. *T. Haageri* has a neat flower of a distinct brick-red

shade externally, bright red inside, slightly stained with brown at the base, the anthers also brown. *T. Spr. ngeri* has longer and more pointed petals, is orange-red externally, light red inside, with the brown stain developed into a more pronounced blotch at the base of each petal.

**The Chinese Plum.**—I note your remark anent this Plum (*Prunus triloba*) being in flower against a sunny wall at Kew. I saw it flowering magnificently in the open in Mr. Ladham's Shirley Nursery, near Southampton, last week. Although it may be a charming wall plant, its proper place seems to be in the open, so that its beauty may be seen. The delicate rose-coloured blossoms are uncommon at this season of the year in the open.—E. M.

**Tulips.**—Mr. Hartland sends us from the south of Ireland a beautiful gathering of Tulips, including forms of *T. Gesneriana*, *T. retroflexa*, *T. macrospeila*, *T. Bouton d'Or*, very handsome, *T. vitellina*, &c. The flowers are of fine size and very clear in colour. We should like to see the species of Tulip oftener, as there is such a variety among them as regards colour and form. What could produce a finer effect than a mass of *T. præcox*, *T. Greigi*, *T. Gesneriana*, or *T. Bouton d'Or*?

**Ranunculus cortusæfolius**, or *grandifolius*, as it is named at Kew, is flowering in the little bog in the rock garden, but it is also to be seen in magnificent specimens grown in pots and now in bloom in the greenhouse. They are well grown and finely flowered, the leaves large and handsome, the flower-spike a yard or more in height, terminated by a flat-branched head of blooms, which are of the richest Buttercup yellow, and each as large as a five shilling piece. This was figured in THE GARDEN of January 13, 1895, p. 28.

**Snowy Mespilus.**—It is not possible to imagine a more handsome object than a tree of this 25 feet high and 20 feet through completely smothered with pure white blossoms. I lately saw two trees in a small garden along the Shirley Road, outside of Southampton, last week. Amongst authorities there appears to be some difference of opinion as to the naming of this shrub. It would be interesting to know its proper name. Perhaps someone will clear up the point for me, as I confess to uncertainty in the matter.—E. M.

**Rhododendron racemosum.**—This pretty new *Rhododendron*, received from Messrs. Veitch for trial, has come quite unharmed through the past winter. It is in an exposed position in the rock garden, and is now a perfect mass of bloom. It is certainly a welcome acquisition and a shrub that may be associated with the choicest alpine flowers, as the little bushes, less than 1 foot in height, are covered with bloom. The flowers are not in crowded heads like those of most *Rhododendrons*, but appear in clusters of two or three in the axils of the leaves all along the shoots. The buds are bright rosy pink, expanding into flowers with pink-tipped petals, shading to white. A coloured plate of this *Rhododendron* was given in THE GARDEN, October 8, 1892.

**Tulips at Kew.**—The only Tulips one generally sees in gardens are the early or late-flowering florists' kinds, but at Kew the species predominate, and some of them fill entire beds, showing unmistakably their beauty and value as garden flowers. Two beds of *T. fulgens* near the greenhouse are specially brilliant; the distinct form and tall, stately character of this species mark it as one of the very best. A curious feature of it is that the flowers are breaking into all sorts of variegations of colour like the feathered and flamed varieties of gardens. *T. Gesneriana spatulata* will be at its best shortly. *T. Batalini*, a fine yellow species, fills several beds. This, too, under cultivation shows a tendency to vary, the petals having a light fringe of reddish brown on their edges. *T. cornuta*, known also as *T. acuminata*, is more curious than showy, with its long narrow petals, but growing in the Grass at Kew it is brighter and even attractive. It is not

worth a place in beds and borders, but it has a new interest when naturalised.

**Charærops excelsa in Surrey.**—Here *C. excelsa* has stood 32° of frost well, and may be classed as perfectly hardy when thoroughly established in this (Surrey) and other counties in the south of England and Ireland. Our plants (about twelve in number) to-day (May 5) look beautiful. They are in a fairly sheltered position and are left uncovered as long as possible. We get some long Fir branches newly cut and stick them well into the ground all round each plant, lacing them round with twine, bringing the points together well over the centre and securing them there. This light protection admits plenty of air, and also obstructs the fierce rays of the sun in early morning after frost. *C. excelsa* likes a rather strong, well-drained soil, with a little artificial manure when established and plenty of water at the roots in dry weather, syringing overhead in the evening.—THOS. WHITFIELD, *St. Catharine's House, Guildford*.

**Violets.**—There are several charming species of Violets not often met with in gardens now flowering in the rock garden at Kew. *V. biflora* is a pretty little gem, but does not quite accord with its name. It has rounded leaves, but the flowers are borne singly on a slender stalk thrown well up above the leaf tufts. They are small, but of a rich yellow colour, with brown lines on the lower petal. *V. cucullata* has heart-shaped, pointed leaves and a profusion of flowers as large as those of the sweet Violet, light violet-blue in colour, the two upper petals larger and broader than the others, giving the flower a characteristic shape. A pure white form of this species was also in flower close by. *V. canina alba* is also worth growing, for though the Dog Violet makes sheets of colour in poor soil where the sweet Violet will not grow, and shows much variation in shades of blue, white forms in a wild state are most uncommon. The variety at Kew is distinct in shape, too, its petals being longer and more pointed than those of the type.

**Flowers from Newry.**—I send you a small gathering of spring flowers, some of which are uncommon. *Mertensia virginica rosea* is quite distinct. *Orobis vernus albus roseus* is the most charming *Orobis* I have yet seen. *Anemone blanda bicolor* is beautiful, buds blue, open flowers white. *Muscari Szovitzianum sub-ceruleum* is, I think, the best of all the *Muscari*; a mass of its charming pale blue is delightful. *Erythronium giganteum* and *grandiflorum* are thoroughly at home here in all aspects. They are very distinct and handsome and remain long in flower; the main distinction between them is that the former is usually one-flowered, while the latter bears from one to five blooms on a scape. *Fritillaria montana* and *messanensis* are distinct and easily grown. *Helonias bullata* in the bog is just opening hundreds of flowers. *Mertensia virginica* is splendid with ample foliage and stems 2 feet high, masses of delightful blue. The *Polyanthuses* in white, gold, orange, and bronze are a grand sight. *Sorbus majestica* with its ample silvery leaves is a most telling tree at the present time.—T. SMITH, *Newry*.

**Clivias.**—There is a large house devoted to these in the Forest Hill nurseries of Messrs. J. Laing and Sons, and although the plants are now rapidly passing out of flower, quite a number of fresh fine spikes was to be seen recently. The plants are interesting, too, in other respects, for some of them were just ripening up the seed-pods from last year's flower-spikes. The plant is not often seen in this state in private gardens for obvious reasons, but these seed-bearing plants are certainly handsome with their great red, oval berries, larger than Walnuts, several in some cases being on a spike. The object here being the improvement of varieties, naturally the number of seed-pods is reduced, but a plant that had a full crop of seed would be bright. Among the varieties still flowering at the time of our visit we noted the following: Right Hon. J. Chamberlain, which recently received an award of merit at the

Drill Hall, and has a fine truss of bright red flowers; Duke of Teck, handsome, broad petals, bright orange; Duchesse of Teck, large in flower and truss; Vivid, extra bright, as the name implies, quite a vermilion-red; and Empress Eugénie, most distinct, of a rosy buff colour shading to primrose in the throat, the flowers large, in a bold truss.

**Prunus Jacquemonti.**—This bushy plant belonging to the *Cerasus* section of the genus is one of the most beautiful of the dwarf species. Several plants are at present in bloom at Kew, the slender, wiry branches of last year's growth being thickly covered with the small rosy flowers. In certain districts of the North-western Himalayas it is a very common shrub at altitudes of 9000 feet to 12,000 feet. It is also found in Tibet and in Afghanistan, one of the plants in flower at Kew having been introduced from the latter country by Dr. Aitchison in 1879. The individual flower is about three-quarters of an inch across, and the leaves, which are lanceolate, quite glabrous, and from 1 inch to 2 inches long, closely follow the expansion of the flowers. A species nearly allied to this and frequently confounded with it is *P. humilis*, a native of China. It is of similar shrubby habit, and the corolla of the flower is of about the same size and colour, but whilst the calyx of *P. Jacquemonti* is long and tubular and has pointed reflexed lobes, that of *P. humilis* is shorter and smaller. The latter species is also a little later in flowering. Both are well suited for planting in groups near the front of a shrubbery or even in beds by themselves.—W. J. B.

**Polyanthuses at Hampton Court.**—At Hampton Court Mr. Graham has been trying the orange and yellow *Polyanthuses*, or bunch Primroses as many now call them, for spring bedding, and with such success that we do not remember to have ever seen anything finer in effect or so fragrant. There are thousands of plants, all of the yellow-flowered strain, and they fill all the beds beside the long walk and the long border on the opposite side. Probably in no garden, public or private, has such a quantity ever been grown at one time. The effect is charming, and a slight admixture of Tulips in different shades relieves the flatness and gives a little more colour. The strain is a good one, but Mr. Graham hopes to greatly improve it by selecting the finest kinds for seed production. This is the third year he has been growing the plants in this way, and a fresh batch is raised each year from seed. We saw the seed beds in which the young plants for next year's flowering were just appearing. The seed is sown in open-air beds protected from birds with nets, the seedlings transplanted when large enough, and removed to their flowering beds late in October. At no time do they ever have glass treatment, and no flowers grown under glass ever made a prettier picture.

**Spiræa arguta.**—The beauties of this *Spiræa* have more than once been referred to in the pages of THE GARDEN, yet it still remains so uncommon that no excuse is needed for mentioning it again. It is of hybrid origin, and was, I believe, raised on the Continent. More than two species probably are concerned in its parentage, but those whose characters most clearly predominate are *S. Thunbergi* and *S. hypericifolia*. The largest plant I have seen is between 3 feet and 4 feet high, and although it may possibly grow to a larger size than that, it belongs to the dwarfest section of *Spiræa*. Its dwarfness is indeed one of its charms, for the wiry-looking stems are arching or semi-pendulous, and all the flowers being produced on the upper side, the beautiful pure white sprays bending outwards in every direction are seen to the best advantage. These flower-clad shoots are those made last year, and are, as a rule, 6 inches to 9 inches in length; to obtain them as long as possible it should be planted in rich loam. So far as I have seen it flowers with uniform freedom, and no restriction at the root is needed either to produce abundant bloom or prevent the formation of over-luxuriant growth subject to damage by severe frosts. It may be increased by cuttings, but the

thin stems do not root readily, and I find it better to layer an old plant, and thus obtain nice flowering plants in a couple of seasons.—B.

## PUBLIC GARDENS.

**Open spaces.**—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, yesterday, the Earl of Meath (the chairman) presiding, six new members were elected, and Lord Teynham was appointed a vice-chairman. It was announced that St. Peter's Churchyard, Walworth, would be opened on May 23 by the Prime Warden of the Goldsmiths' Company, that company having provided the association with funds for the laying out of the ground; that Woolwich Churchyard would be open as early as possible in June, that six seats had been accepted for Bartholomew Square; that the remainder of the churchyard of All-hallows, London Wall, had been made available for the public; and that the association would shortly erect gymnastic apparatus in the playground recently added to St. Nicholas Garden, Deptford. It was agreed to offer to lay out St. Mary's Churchyard, Bromley-by-Bow: to take steps to acquire, if possible, a triangle in Hornsey Rise, an enclosure in Upper Street, Islington, and other sites; to offer seats for St. Peter's Churchyard, Cornhill; and to negotiate for the improvement of the Brixton Oval, the remainder of Stockwell Common, a Jewish burial ground in Fulham Road, Walcot and St. Mary's Squares, Kennington, Arbour Square, St. Stephen's School Ground, North Bow, and a disused burial ground in Globe Road, Mile End. It was also agreed to co-operate with the other open spaces societies in efforts to secure the preservation of the Bute House Estate, Petersham. A letter from the association to the London County Council was read and approved, pointing out recent cases of building apparently infringing the provisions of the Disused Burial Grounds Act, 1884, and the Open Spaces Act, 1887. Particulars of certain vacant sites in Canning Town, Mile End, and Walworth were brought before the meeting.

**Royal Horticultural Society.**—The next meeting of the society will be held in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, May 14, when a large show of hardy flowers, Daffodils, &c., is anticipated. At 3 p.m. Dr. Morris, of Kew, will deliver a lecture on the "Plants and Gardens of the Canary Islands." The lecture will be illustrated by dissolving views from the magic lantern.

**The weather in West Herts.**—All the days during the past week have been warm, and one or two of them very warm for the time of year, but as a rule the nights have proved moderately cold. On the 6th inst. the maximum reading in shade was 72°, which is very high for so early in May. During the last six days the temperature of the ground has been rising rapidly. At 2 feet deep it now stands at 54°, and at 1 foot deep at 58°, and at the latter depth is about 3° higher than the May average, and 5° warmer than at the same time last year. No rain has now fallen for seven days, and owing to the rapid evaporation that has lately taken place, the soil is already becoming dry. Throughout the week the atmosphere has been singularly dry. In fact on the 6th the difference between the readings of an ordinary thermometer and one with its bulb kept constantly moist amounted to as much as 16° at three o'clock in the afternoon. The record of bright sunshine has also been remarkable, the average daily duration amounting to nearly twelve hours. For only six hours altogether has the wind during the week taken any other direction than some point between north and east. A Blenheim Orange Apple came into blossom in my garden on the 7th inst., which is one day later than

the average date of the first flowering of the same tree in the previous nine years, and twenty-five days later than last year.—E. M., *Berkhamsted*.

**Slugs.**—We have a dreadful plague of garden slugs in this neighbourhood notwithstanding the severity of the winter. One would almost think it had been raining slugs. We have slaughtered thousands by night, which is the only efficacious way of curing the evil. Lime and soot are useless when they have once been rained on, and in any case they only drive the slugs away to feed and breed elsewhere. Nature and slugs will not alter their laws to suit the convenience of man, and the convenient bird theory will not go down very long with the master who wants his flowers. I saw a bed of seedlings three nights ago with the rows full of stalks, husks of seeds, and small holes. I held a *post mortem* inquest on the seedlings with two friends, and we could come to no decision. The next day I called my man and asked his opinion. "Why, sir, it's the finches; don't you see the husks of the Sunflowers. I have driven them off ever so many times." I was not satisfied, for no finch could have made the holes I saw, unless he kept for the occasion a spare beak about the size of a rook's. So I watched, and in the evening killed off about 50 square feet over 100 slugs. I told my man, and when he went up later on with a candle he found the seed bed swarming. The slug eats the seedling; the seedling withers; the lob worm fetches down the dead seedling; the lob worm brings up the husk, if any; the lob worm makes the hole; the finch is not in it.—J. WHITWORTH SHAW, *New Place, Lingfield, Surrey*.

## OBITUARY.

**Mr. J. Walker.**—We regret to announce the death, at the age of 76, of Mr. J. Walker, of Thame, Oxon. He died on Wednesday from an attack of apoplexy. Visitors to the R.H.S. meetings for many years past will have a vivid recollection of the splendid blooms of *Maréchal Niel* Rose that he used to exhibit in the early months of the year. Mr. Walker devoted much of his time to the improvement of the *Dahlia* and *Sweet William*, many fine varieties of each of which were raised by him.

**Death of Mons. D. Hooibrenk.**—I regret to inform you that M. Daniel Hooibrenk, a well-known gardener, has just died at the ripe age of 83 years. A native of Holland, he went to Paris and thence to Vienna, where he took charge of the celebrated gardens of Baron Hügel. From 1837 to 1849 he had charge of the famous collection of plants. When Baron Hügel gave up his gardens and the collection of plants was dispersed, M. Hooibrenk started with a part of it as nurseryman, and his work in gardening is well known. He was nominated by His Majesty the Emperor of Austria Knight of the Franz Josef's Order, and Napoleon III. conferred on him the Order of the Legion of Honour for a treatise on the cultivation of the Vine.—LOUIS KROBATZKI.

**Beetles in the house.**—Would "G. S. S." kindly say a few words about enclosed insects? The larvae, which very much resemble wireworms, occur here constantly in the coal-ashes under a fireplace in a kitchen, and the beetle is pretty often met with in various parts of the house.—W. M.

\* \* In reply to the above the insects you inquire about are the larvæ and perfect insect of the cellar or churchyard beetle (*Blaps mortisaga*), a not uncommon but by no means abundant insect. The larvæ more resemble mealworms than wireworms; indeed, they are nearly related to the former. More than once there have been instances of the larvæ having been ejected from the stomach of a person. Westwood quotes two cases: one was accounted for by the woman having daily drunk for some time water mixed

with clay taken from a grave. This insect is often found in cellars and outhouses and in churchyards. They appear to love moisture and darkness. It is curious that the larvæ should be found in such a dry place as the ashes under a kitchen fireplace. Perhaps there may be some cracks in the hearth beneath leading to holes in which they find a congenial habitation, and where, perhaps, some leakage from pipes or the boiler may afford them moisture. One would think from their long legs that the beetles were active, rapidly moving insects, but the reverse is the case, and they move about in the most demure fashion. The beetles are long-lived and of great vitality; they have been known to recover even after having been imprisoned in a bottle of spirits of wine for twelve hours. I do not think they do any harm in a house. If you wish to exterminate them I should clear away any rubbish, &c., near their haunts in which they can hide, and if there are any cracks or places in the floor into which they can creep, I should pour boiling water into them and fill them up with cement.—G. S. S.

**Grubs in Strawberry ground.**—I shall be obliged if you will tell me the name of the larva sent, also the best means of destroying them. I planted a large area to Sir Joseph Paxton and President Strawberries in deeply trenched Grass land done late in 1894 and early in 1895. Three acres of the ground are planted to dwarf Apple trees and bush fruits. They are looking very well. The Strawberry plants daily disappear by the 100. Half an acre I am planting Potatoes in. The whole piece of ground appears to be frightfully infested. I found those sent under two runner plants.—J. A. PORCH.

\* \* In reply to the above, the grubs you enclosed are those of the common daddy-longlegs or crane fly (*Tipula oleracea*). They are most difficult pests to destroy. It is not of much, if of any use employing insecticides. Keeping the ground well worked is useful in disturbing the grubs and giving the birds a better chance of getting at them. Nitrate of soda 2 cwt. to the acre and well watered in helps the crop, and is distasteful to the leather-jackets, as these grubs are often called from the toughness of their skins. Pieces of turf, slates, or tiles should be laid about near their haunts, as they often roam about at night and creep under such things for shelter during the day. These traps should be examined every morning.—G. S. S.

THE ART ITSELF IS NATURE."—Shakespeare.

## FLOWER GARDEN.

## PRIMULA ROSEA AND P. DENTICULATA.

THESE two Himalayan Primroses have never made a better show or been more healthy at flowering time in my garden than this year. I am so often asked how I manage them, that I am induced to send this note for the benefit only of those who are not already satisfied with their success. In *P. denticulata* I include *P. cashmeriana* and some other varieties with unauthorised epithets added to the name. All of them grow from the same seed and have flowers ranging in colour from very pale to very dark purple, and leaves more or less mealy, according to accident. *P. rosea* also varies much in the intensity of the colour and the size of the flower, but not otherwise. This species also varies the name by superlative and superfluous Latin additions, and as any individual plant may be multiplied at pleasure, growers may choose the plant they prefer and keep it.

I give notes on the treatment of *P. rosea* first. The compact network of matted roots in this species binding the soil beneath it into a solid mass is a remarkable feature. The effect of this is that two years after planting all the food within 6 inches of the bottom of the plant has been so completely exhausted, that the Primrose dies of starvation. Life may last a year or two longer, according to soil and circumstances, but three years is its utmost limit in my garden. The soil for growing it must be fine and retentive and the situation sheltered, for though the species is very hardy, the flowers are often quite spoilt by spring frosts in exposed aspects. I prefer the north side of a wall or of a sheltered slope, for spring frost is less injurious to flowers facing north provided they are not exposed to sweeping blasts. Seed gathered from the best varieties may be sown as soon as ripe to get new selections, but a group of seedlings does not flower evenly or look as gay as a well-regulated group of divided plants. Division is hardly the right word for the treatment which *P. rosea* requires. After flowering, the plants should be dressed over the crowns with fine soil to encourage surface-rooting; then at any time between June and August, choosing wet weather, the clumps should be lifted, the mass of old roots cut off within an inch of the base of the leaves, and the plants carefully divided into single crowns. The leaves must not be injured, for if the leaf-growth is seriously checked by withering or bruising, the pieces may as well be thrown away. Till the leaves are firm and growing again, the plants should be shaded and well watered. I generally plant them in wooden trays 6 inches deep. The larger the number taken, say not less than 1000 at once, the less likely they are to be neglected. If the first batch fails, try a second, and a third. Each two-year-old plant will supply twenty or thirty crowns, so there need be no lack of material. These pieces should not be left too long—say not more than two months—without replanting in the place in which they are to remain, otherwise the roots will get hopelessly matted together. At any rate let them all be in their flowering places by the end of September, and do not expect them to flower well for more than two seasons.

This process must be repeated every year; the garden will then be stocked with yearling and two-year-old groups. This plan gives the best results. Dividing the old plants after the leaves are dead, in which case some of the old roots must be left, is less troublesome, but less successful. Last winter I tried dressing some of the groups with superphosphate, say a quarter of a pound mixed with a peck of soil to each group. The result was an enormous crop of flowers, two or three stalks with about thirty flowers each, on every plant, but many of the stalks were fasciated and the flowering was almost overdone. Two-year-old plants not so treated produce the same number of bunches, each expanding twelve flowers at 6 inches high. A good flower is just an inch across. This may seem large, but my strain has been improved by long selection. The above treatment may be varied by way of experiment, but frequent division in some way is a necessity.

*P. denticulata* is more easy to deal with, as it is best when raised from seed. The finest heads, both in size and colour, should be marked for seed, which may be sown as soon as ripe; it comes up so freely, that one head will easily give a thousand seedlings. When sown in June it will seldom grow into flowering plants by next spring, but the habit of root is so different from that of *P. rosea*, the roots being few and very long and large, that seedlings may continue close together in the pans until of considerable size or be planted out, a hundred or more in a square yard, and selected according to their size and forwardness for their flowering places. These, too, suffer from frost only when in bloom, and as they often try to flower soon after Christmas, every means must be taken to retard them, especially by transplanting late in autumn before the flower-buds are formed. After flowering, plants may be divided; even single crowns may be cut into quarters, or plants may be beheaded, and a crop of young ones will grow out of the stump of each root; but in spite of this great vital power, divisions are apt to look shabby, and seedlings are far better. This species sows itself, young ones coming up all round almost as thickly as round *P. japonica*, and these must be thinned before flowering; but those which are allowed to remain, especially at the sides of shrubby walks, flower better than those transplanted. Above all, clear away the old plants after two or at most three flowerings, as they become shabby and encumber the soil. The best show I have this year is under Gooseberry bushes, where they do not conduce to the encouragement of gigantic fruit, but look very ornamental in early spring, getting just enough shelter to save the flowers. Neither of these species forces well, but both are admirably adapted for cold frames, doing better in roomy boxes than in pots. In this way they may be made a useful ornament for a conservatory in February and March. To sum up, sufficiency of food and frequent renewal from a well-selected stock are the great points to be attended to in maintaining a good show of these early spring favourites.

Edge Hall, Malpas.

C. WOLLEY-DON.

**Lilium Henryi.**—As an all-round garden Lily this bids fair to be one of the finest species we have, as it is of such robust constitution that it will thrive under conditions such as many Lilies will absolutely refuse to grow in. The last winter, too, should be a good test of its hardiness, and in this respect, as far as my experience extends, it stands before a great many, for a couple of bulbs left in the open border without any protection whatever are now growing beautifully—in fact, much stronger than last year, while under exactly

similar conditions *L. nepalense*, *L. neilgherrense*, and *L. sulphureum* have all perished. The Bermuda Lily (*Harrisi*) and the Japanese forms of *L. longiflorum* are also pushing up in a weak and irregular manner. Up to the present, as far as it has come under my own observation, *L. Henryi* seems proof against the dreaded Lily disease, which plays havoc with many Lilies. A few years ago *L. candidum* and *L. auratum* were about the only two liable to be attacked, but now many species suffer greatly. Besides the two above mentioned, I have seen established clumps of *L. davuricum*, *L. speciosum*, and *L. tigrinum* dwindle away in the same disheartening manner. In justice to *L. speciosum*, it should, however, be mentioned that the clumps which perished were in close proximity to some masses of *L. auratum*; whereas some other plants of *L. speciosum* at a little distance therefrom were uninjured.—H. P.

## NOTES ON SNOWDROPS.

THE past winter has not been an ideal one for Snowdrops, and the severe weather delayed so many that their beauty was soon gone. The kinds which flower in late autumn or early winter were unusually late, and it was about December before such *Galanthi* as *octobrensis*, *corcyrensis*, and similar species or varieties came into bloom. Frost and snow overtook them before their flowering was over, and it was wonderful how unscathed many of them seemed when the snow departed. These kinds, generally bad doers, seem all to grow well here. I am sorry to say that *G. Olge*, of which I purchased a bulb at a good price in autumn, did not flower. Careful examination of a considerable number of these autumn-flowering Snowdrops leads one to the conclusion that there are too many names among them, and that a revision would be very desirable if it could be obtained. I fear the prospect is not very promising for this.

The other Snowdrops, as has already been indicated, were so late that the bright weather and sharp night frosts soon despoiled them of their beauty. I regret to say that the Snowdrop fungus has been more virulent this year, and through its ravages I have lost some of my most prized kinds. It has been more destructive among Snowdrops grown under the partial shade of trees than among those in full sun, and it is possible that a good "sun bath" may be found beneficial in the way of prevention. It is very galling to see some of your best flowers falling a prey to this fungus and to feel absolutely unable to prevent their decay. I think we have no newly-introduced Snowdrops to say anything about, *i.e.*, none of this year's introduction. Our generous friend Mr. Whittall does not seem to have met with any new ones last year, although in other directions his indefatigable exertions are doing much to increase the interest and beauty of our gardens. We are, however, better able to appraise the merits of some sent the previous year. Of these I think I have grown nearly all, although some have not flowered even yet.

The Cassaba Snowdrop is one of the largest and finest in my garden, having great, massive flowers and long, broad leaves. I have very few bulbs of this variety, but should those I have be an average sample of this variety of *Elwesi*, it should be one of the greatest acquisitions to our gardens. The *Aidin* one, which I understand to be the one named *Elwesi* var. *unguiculata*, has not this year shown the bold, defiant habit which distinguished it in 1894. It has, however, developed other merits, *i.e.*, by producing a large number of flowers from the same bulb, and by showing a marked tendency to produce offsets. Bulbs of this variety, very kindly sent me in 1894 by Mr. Whittall,

present the bold habit this Snowdrop has the first year after importation. The Kas Dagh variety of Elwesi has improved considerably, but is still not equal to some other varieties of this handsome species. The Galanthus from Samos seems rather tender and produces a small, thin-petalled flower of the Elwesi type. The one from Phœnika, Samos, seems even more tender, having been badly cut by the frost, and did not flower. That from Ananas Dagh, which looked as if it might prove rather like the Cassaba one, did not flower this season and seems entirely of weaker growth. One sent me last year by Mr. Whittall as ochrospeilus presents no points of difference by which it can be distinguished from the typical Elwesi, and I think it possible that the collectors employed by our benefactor may have made a mistake. The Cassaba and Aidin Snowdrops are decidedly acquisitions, and if the former has not yet received a distinctive name, I hope it may be honoured with the name of Mr. Whittall, as it would be a pity if his interest in the Snowdrops could not be marked in some such way.

Turning to other Snowdrops, I find there is some criticism of *G. Elwesi robustus*, it being said that it is not distinct enough to have a varietal name. I must demur to this, as it is quite distinct from the ordinary varieties of Elwesi. It is of tall growth, bears large flowers, and has great, broad leaves, much larger than those of the ordinary forms. Its defects are that the flowers, although large, are hardly large enough for the plants, and its leaves are not so elegant as one would desire. I should rank it as inferior to the Cassaba Snowdrop, but still as worth growing.

The Galanthus I received from the neighbourhood of Broussa in 1893, and which was pronounced to be almost, if not quite the same as byzantinus, has not, I am sorry to say, turned out to be a good garden plant. It does not improve under cultivation, and can hardly be considered an acquisition. It looks like a natural hybrid, and is particularly variable in leaf and in time of flowering. *G. Ikarie*, on the other hand, has shown its capabilities by withstanding our last severe winter, and by its retaining its good habit and distinct appearance. It is another of Mr. Whittall's introductions, which should have been mentioned along with his others. Of Mr. Allen's charming seedlings I have some diffidence in speaking, inasmuch as a number of those for which I have been indebted to the great kindness of the raiser have only flowered for the first time this year, and will not show their full beauty for another year or so. One cannot, however, while admiring them refrain from hoping that the dreaded fungus may spare such lovely flowers as Talisman, Aurora, Elwesi Beauty, Galatea, and the others in my garden. The yellow Snowdrops, *G. lutescens* and *G. flavescens*, have been particularly pretty this year, their yellow ovaries and markings of the segments being very pleasing. *G. nivalis poculiformis* has also been pleasing, and while *G. Van Houttei* within a few inches of it has disappeared, this rather delicate pure white variety is quite healthy. One cannot understand the erratic way in which *G. plicatus* and its varieties die off without any apparent cause. The green Snowdrop, *G. virescens*, grows upon one from year to year, as also does the curious twin-spined *G. Scharloki*, while such fine flowers as *G. Imperati*, *Atkinsi*, and *G. Melvillei* enlist our admiration from year to year. I hope Mr. Allen and others who know the Snowdrop better than I do may still give us their experiences of the "early herald of the infant year." The season is now over, but even amid the delights of the present time with its

hosts of Daffodils, its Tulips and the many other charming flowers of spring, we can surely cast a look back upon the chastest flower of all, the Snowdrop. S. ARNOTT.

*Carsforth by Dumfries, N. B.*

#### FLOWER GARDEN NOTES.

APRIL FLOWERS.—A retrospect of the month's display in the hardy flower garden is always instructive, because there is a reminder to take special note of those things that have been a success with the view to increase them at the first opportunity. The outdoor flowers of April, too, are naturally the product of perfectly hardy plants, and within the reach of all either in large or small quantities. So far as the April flowering shrubs are concerned, the display has been remarkably good, and in all cases where any one particular family or special varieties are wanted together in considerable numbers the effect has been quite up to the average. In the matter of this particular style of planting I do not mean huddling them close together so that they lose their individuality; this is by no means necessary. The plants should stand just clear of each other and be kept so by careful and judicious pruning, close enough so that when viewed from a distance a mass of colour is shown, and yet with a perceptible drop between the plants so that a table-like surface is avoided. The Ribes family rank among the best of early-flowering shrubs, and some of them seem as yet imperfectly known. *Sanguineum* is, of course, common enough, but it is not the case with *s. album* and *atro-rubens*, which flower with equal freedom and make a fine display when planted in large clumps. All the forms strike readily from cuttings and make capital little bushes by the end of the second year. Beautiful white-flowering shrubs of the same season are *Spiræa prunifolia* and *S. Thunbergi*. The foliage of the latter is of a very vivid green, showing off to advantage the sprays of tiny white flowers. A variety of colour is furnished by the *Cydonias* in different shades of scarlet, pink, flesh colour and white. I was afraid the two last-named—and more especially the white—had been seriously affected by the weather experienced in February. It was, however, only a browning of the buds, not enough to affect their development, as all the varieties have flowered splendidly. Yellow tints have been supplied by *Forsythia suspensa* and *F. viridissima*, two very useful April shrubs. The Daffodil is the hardy flower of April, and, so far as the present season is concerned, *Barri conspicuus* has been the king of Daffodils. Other varieties both in the trumpet and star sections may rank higher as individual flowers, but for furnishing a grand display *Clumax* commend me to the above-named sort. Flower-stems thrown up from strong selected bulbs were of extraordinary vigour. I did not measure any of them, but many must have been close on 2 feet in length. The above variety, as the statement indicates, was planted at the end of last summer on a well-prepared border. Common sorts naturalised where the soil and situation have suited them have flowered well, and as early varieties were kept in check by the severe weather, April has been more than ever the Daffodil month. The *Doronicums* have helped to increase the prevailing yellow shades furnished by Daffodils and some of the Polyanthuses, and have flowered well. A very fine display of pink trusses of flower, both as to size and quality, is still to be found on the old *Megasea* (*Saxifraga cordifolia*). I saw a lot of this the other day at the back of a sloping border faced by a good breadth of a terra-cotta-coloured Polyanthus, and the effect was very pleasing. The white Arabis, the purple Aubrietia, and *Violas* of similar shades of colour also make an effective display when associated with the *Megasea*. I said above the Daffodil was the flower of April, but a thoroughly good strain of Polyanthus runs it very close indeed, and personally I should prefer the latter. A north-west border 200 yards long by 4 feet wide

has been a lovely sight, and furnished us with a wonderful wealth of cut flowers. The plants were arranged as near as possible in colours for the sake of seed-saving, but a general mixture is the more effective. If all the different shades are well mixed together, the result is a beautiful display that can hardly be furnished by any other flower.

WALL PLANTS.—There has been a general look round the walls during the past week in order to remove any plants or portions of the same that failed to stand against the severity of the past winter, and although the losses are fortunately not heavy, one or two things are gone that we did not care to lose. The silver variegated Buckthorn is one; the portion of wall furnished, by the same always looked bright, and the long stems were very useful occasionally in a cut state. Fortunately there are some vigorous Dijon Roses on either side the Buckthorn that will quickly fill the vacant place. *Lonicera flexuosa* is entirely gone, and the golden *Lonicera* growing on the stem of an old Judas tree is badly crippled. We shall get some back-breaks on this Japanese Honeysuckle that will give a bit of life to the plant, but there is no prospect that the trunk of the old Cercis will be clothed from base to summit with a mass of foliage and flower as in previous years. It is not as yet an easy matter to estimate the damage on the varieties of *Ceanothus*. As stated in previous notes, these get very little pruning, with the exception of weeding out weakly stuff, and, so far as the strong shoots that were left are concerned, they seem to be cut back close to the branches, but there are signs of breaking away at the base of each shoot. The remarks already made as to the bush plants of *Cydonias* are applicable to those on walls, the buds were so brown as to lead to the inference that flowers would be very scarce, especially on the white variety. This, however, is not the case; the plants have been literally covered with bloom, and since the expansion they have not, as last year, had an exceptional frost to bring the flowering season to an abrupt termination. Roses on walls have not suffered at all with us, except in the one or two instances where they were exposed to the full force of the very bitter winds. Roses in variety are undoubtedly the most useful wall plants we have, the little shelter brings them along rather earlier, and the flowers from the wall hit the season between those produced under glass and others that are growing, as the ordinary standard and bush forms, on the open quarter.

Claremont.

E. BURRELL.

*Daphne Blagayana* has come through the trying winter and kept on flowering since the latter end of March. Light, but moist vegetable soil seems to suit it. The only needful thing to do in the case of strong specimens is to first find the stems near the older part of the plant, then sever them and leave them *in situ*. This done soon after flowering and the severed offsets left until September will cause them to develop plenty of new fibre, and render them fit for being dealt with separately.—J. Wood.

White Stocks.—These are now to be seen in quantity in Covent Garden Market. The Brompton and the East Lothian are both grown, but the latter is the favourite. For several months past this Stock has been offered in the London markets, but of course not in such abundance as at the present time. For purity and fragrance nothing can excel a good strain of Lothian Stock. The blooms can be used individually, wired up for wreaths and bouquets, or the spikes can be employed for decoration. For early blooming the seed must shortly be sown and the young plants shifted along, so as to get them well established in 6-inch or 7-inch pots by the autumn. They can then be subjected to a mild forcing temperature. This is the surest way of getting early bloom, but for a main supply a simpler method is pursued. The plants are put out under glass in autumn, and under such circumstances they give a wealth of bloom in April and up to June.—J. C. B.

## YUCCA RECURVA.

THOSE who seek sub-tropical effects and place tender plants in the open air for that object often neglect the noble hardy plants, of which there is a good selection, capable of making striking pictures of luxuriant vegetation, with few or none of the disadvantages entailed in the

time of the year. When from the centre of this great crown of leaves the flower-spike, rising several feet high, becomes a pyramidal mass of sweet, ivory-white flowers, no hardy flowering plant can compare with it in beauty. This Yucca should be frequently planted in our gardens, so as to have specimens of different

them. It is easily increased by detaching its fleshy root crowns, which soon make strong young plants if started in a frame or greenhouse. It is well to examine large plants after a fall of snow and shake out any that remains in the crown, as if a thaw by day is followed by frost at night, much damage will be done.

*Yucca recurva.* Engraved for THE GARDEN from a photograph sent by Mr. J. Pullham, Brossbourne.

use of plants that can only be placed outside in summer. The Yucca family is a host in itself, and one of the very best Yuccas is that here illustrated. In all states, young or old, with its graceful curving tufts of leaves rising from the ground or borne high on the stout stem, it is always a handsome plant and effective at any

ages succeeding each other in flower year after year. It grows best in a warm, well-drained soil such as that of the Thames valley. When one of the evening fêtes was held at Chiswick some years ago, a dozen of these Yuccas were all in flower at one time, and the picture was one not likely to be forgotten by those who saw

## APRIL IN SOUTH DEVON.

THE mean temperature of April, although 3° below that of April, 1894, was 13° above that of the average for the last seventeen years, which is 46.5°. On only one day (the 13th) did the thermometer on the grass drop below freezing point, and then only by one-tenth of a degree, though on three occasions—the 1st, 2nd and 15th of the month—the mercury fell to 32°. Rain has fallen on thirteen days to the extent of 2.43 inches, against 2.39 inches on seventeen days during April, 1894, the average rainfall for April being 2.69 inches. The total fall recorded during the first four months of 1895 is 9.65 inches, as compared with 10.22 inches for the corresponding period of 1894. As regards sunshine, April, 1895, has proved almost a counterpart of April, 1894—166 hours 49 minutes of sunshine having been recorded this year and 166 hours 30 minutes last year. From January 1 to May 1 there have been 491 hours 49 minutes' sunshine against 502 hours 35 minutes during the same four months of 1894. The total horizontal movement of the wind has been 6339 miles, the greatest daily total being 492 miles on the 6th—an average of 20.5 miles per hour. The greatest hourly velocity was registered between 11 a.m. and noon on the same day, when the rate of 41 miles per hour was reached. The wind has blown from the south or west for eighteen days, and on twelve days from north or east.

In the flower garden April is a month of promise as well as of bloom—promise in the swelling buds of the Peonies, in the ascending spikes of the Lilies, from the sturdy growth of *L. giganteum*, that bursts up through the earth as big as a man's fist, to the slender shoot of *L. canadense*; promise in the glaucous sheaths that enfold the Iris blossoms, while for bloom we have the families of the Narcissi, the Hyacinths and the Tulips; and what a thrill of delight at vivid colouring is given by the glowing scarlet of a mass of Tulip Vermillion Brilliant. The tall Crown Imperials perfected their pendent bells of pale yellow and of red, in the bases of which lay quivering the single drops of moisture that the children call "toads' tears." Narcissi, always a joy, have not given us such a lavish display as usual, *Stella* being the only variety that has bloomed profusely. Poppy Anemones have been mostly a failure, such foliage as was above ground at the end of the year being destroyed by the long frost. *Anemone fulgens*, than which no handsomer variety exists, after the first year invariably flowers poorly, fresh roots having to be procured yearly if a good effect is to be secured. The *Dondia* covered a corner of the rockery with a carpeting of its quaint flowers, which formed a striking contrast to the fragile white blossoms of *Thalictrum anemonioides* that was blooming hard by, while *Anemone ranunculoides*, with its bright Buttercup-like flowers, made a charming patch of gold in the background. This *Anemone* is not grown so largely as its merits deserve, and should certainly not be neglected by those who grow *A. apennina*, the two varieties flowering at the same time. The little Grape Hyacinths, of which Ruskin writes that the flower is "as if a cluster of Grapes and a hive of honey had been distilled and compressed together into one small box of celled and beaded blue," lifted battalions of their scented spikes from the brown earth, which towards the end of the month was on all sides carpeted with the azure of the Forget-me-not. In the lanes and hedgerows the white Violets were a full month later in their arrival than was the case last year, the Primroses, however, making up for their tardiness by blossoming in unwonted profusion. Now that the sap is running strongly, the mis-

chief that has been wrought by the severe winter can be seen on all sides. *Ceanothus* and shrubby *Veronicas* are mostly killed. *Escallonia montevidensis* is dead, and so are *Benthamia fragifera* and *Rhus Cotinus*, while *Escallonia macrantha* and *Berberis Darwini* have been very badly cut. Curiously enough, *Choisya ternata* in a very exposed situation is merely a little brown at the tips of the leaves, thus proving a much harder subject than was at one time thought.

Apple and Pear trees are looking well and are full of blossom, appearances at present promising well for a good fruit crop. S. W. F.

## THE ROCK GARDEN.

### VII.

APRIL 30.—During the past week the temperature has been much cooler and rain has fallen in abundance. Sunny hours have been few and far between, and, as a natural consequence, the number of fresh plants in bloom is not so large as it might have been. There are, however, among the new arrivals several handsome and interesting kinds, many of them well adapted for being grouped together for combined effect.

### TINY GEMS IN BLOOM.

Last week I mentioned several choice *Androsaces* which might be grouped together in the select part of the rock garden. These are still in bloom, and as yet have lost but little of their beauty. The choicest rock plants which have opened here this week are *Eritrichium nanum*, *Saxifraga calveiflora*, and *S. aretioides*; these go exceedingly well together, and are also very fit companions for the *Androsaces* already mentioned, although they commence to bloom a week later. *Eritrichium nanum* (the little Fairy Forget-me-not) is doubtless a gem of the first water, with its peculiar cushion of hairy foliage and its bright blue flowers. A great drawback is the difficulty in its cultivation. It flowers and thrives in the rock garden easily enough during the summer months, when it loves also plenty of moisture at its roots, but during the winter it is so susceptible to wet that even a few drops of rain on its hirsute foliage may be sufficient to cause its death. The best way of planting the *Eritrichium* is to put it into an almost vertical fissure, so arranged that the roots can have plenty of moisture and no water can rest on the foliage, which latter might during the winter receive the additional protection of a piece of glass. *Saxifraga calveiflora* (from the Pyrenees) is a very distinct and handsome plant; its short and comparatively broad encrusted leaves are pointed at the apex and arranged in a somewhat elongated rosette, from the centre of which the bright red bracts and flowers are produced on a stout stem 3 inches high. It does not grow well in ordinary soil and objects to limestone, but when planted between two stones and into gritty soil which has received an abundant admixture of broken flints or granite it does remarkably well, especially in a sunny position. *Saxifraga aretioides* is also from the Pyrenees, and an excellent companion to the former. Its flowers are deep yellow, and its stem and calyx are partly tinted a bronzy brown. The very minute leaves are arranged in tiny silvery rosettes packed together so closely as to resemble more an *Androsace helvetica* than a *Saxifraga*. It does best in a sloping position where it would be well drained. *Saxifraga lantoscana superba*, which is also just coming into bloom, cannot be called a "tiny" gem, as it grows more freely than either of the varieties mentioned. Its rosettes of handsome encrusted leaves and its compact spike of large pure white flowers are, however,

so beautiful, that it deserves a good position in the select part of the rock garden.

### OTHER ROCK PLANTS IN BLOOM.

The following plants now blooming in various rock gardens in this county would be too rapid in their growth to be associated with the smallest plants; they are, however, indispensable in the rock garden, and it is well to allow them the space they require if other plants are not to be endangered. *Dryas octopetala* quickly forms a spreading evergreen carpet, now studded with large white flowers; it loves a moist and sunny position, and is best adapted for level ground. *Dryas Drummondii*, with yellow flowers, and *Dryas lanata*, with cream coloured flowers and slightly woolly leaves, are good companions for the former, and also now blooming. Another carpeting plant too well known to need any further description is *Arenaria balearica*, which is more suitable for covering stones, to which it clings very closely, especially in a half-shady position. *Gentiana acaulis*, the commonest, but after all the very best of all *Gentians* for forming large masses, is in splendid form just now. A moist position and gritty soil are what it loves best. Another charming blue flower is *Veronica saturcioides*; it has very small leaves and upright racemes of flowers; not only the petals, but also the stamens are blue and bear purple anthers discharging whitish pollen. *Rhodiola rosea* is in full bloom; its glaucous leaves and yellow flowers remind one of *Sedum*. It is, however, not an evergreen, but is invisible during winter. The alpine Forget-me-not (*Myosotis alpestris*) is also in bloom, its blue flowers forming a capital contrast to the large white blossoms of *Ranunculus amplicaulis*. This, by the way, does not spread very fast, and to make an effective group several should be planted close together. It is a very desirable plant, seldom growing more than 9 inches high. *Ranunculus gramineus*, with grass-like foliage and yellow flowers (much smaller than those of *R. amplicaulis*), is also effective. *Saxifraga Walpacci* and many others of the larger kinds of *Saxifragas* now begin to show their white flowers to great advantage. These will grow in almost any soil and in any position, and are best adapted for growing in masses not on, but between the more massive rocks and carpeting the bare soil between larger plants. The double form of *Saxifraga granulata* is very pretty with its double white flowers, but it is not an evergreen. *Tiarella cordifolia*, the Foam Flower, is best assigned to a semi-wild spot in the background of the rock garden, where it may ramble as it pleases under the shade of shrubs. A half-shady spot might be reserved for the vigorous American Violet, *Viola cucullata*, and its white form, *Viola cucullata alba*.

### LARGE PLANTS IN BLOOM.

There are several of the larger plants now blooming which will grow in ordinary soil, and might with good effect be arranged as single specimens or in colonies on open spaces between the groups of rocks. There are for sunny places the yellow *Stylophorum diphyllum*, *Anemone narcissiflora*, with pure white flowers; *Geum montanum*, yellow; *Doronicum excelsum*, yellow; and the handsome varieties of *Megasea*, such as *M. crassifolia* and *M. purpurea*, with pink and purple flowers and evergreen, large, catherly leaves, most suitable for bold effects.

In moist soil and in a half-shady position the handsome *Mertensia virginica* is now in full bloom, with its drooping raceme of blue flowers.

*Eschr.*

F. W. MEYER.

(To be continued.)

### SEEDLING DAFFODILS.

I SEND a few seedling Daffodils, some of which, as will be perceived, are from the old double and vary somewhat in form and colour. I have often thought that the old Ajax *Telamonius* might be improved, and in one respect I may claim to have made a step forward. One of my seedlings, which resulted from crossing the old double with the Tenby, blooms from ten days to a fortnight earlier than the old form. I have over a period of five years proved this early-flowering character to be fixed and not in any way dependent on the weather. Growing side by side, this seedling is invariably nearly or quite a fortnight in advance. Everyone knows how valuable the old double yellow is for growing under glass. A form of it that naturally flowers two weeks earlier than the type ought to be useful. I feel confident that this will at some future time be in favour as a market Daffodil both under glass and in the open air. Florists to whom I have supplied flowers of it are of this opinion. I have also a seedling which is as regards time of flowering just the reverse of the preceding. It comes into full flower just as the old Ajax is passing away, so that these two varieties extend the blooming period of this Daffodil nearly or quite a month. This late blooming form has very big flowers, which, as will be seen by the bud enclosed, are wonderfully vigorous, even more so than in the parent. The old double Daffodil can be established with ease in the meadow, woodland, or orchard; it flourishes in all soils, and is so effective when in bloom, that I think all lovers of flowers, and particularly of Daffodils, would desire to prolong its flowering period. The parti-coloured double flowers, which are composed of white and yellow petals, represent an attempt to raise double white Daffodils. I hope they are a step in the right direction, for I see no insuperable obstacle to obtaining a race of double white varieties having large blooms and of robust, vigorous constitution. The flowers sent are from the same pod of seed and vary, as will be seen, in doubleness. They are the produce of small bulbs but four years old from the seed. In a general way seedling Daffodils take from five to seven years to flower, and in my experience they do not attain to their full bloom-bearing powers until they are a couple of years older. The plants that gave these flowers are very green and vigorous looking, and I am, I think, justified in assuming that in due course they will yield blooms double the size of those sent. The small flowers are from *obvallaris* and *nanus*; this cross gives quite a succession of bloom. The single yellow trumpet is from *Emperor*, but I am not aware with what it was fertilised. It seems to be as good as its parent, and is about ten days earlier than that grand Daffodil. It will probably be bigger another season. Being so early, fine in colour and remarkably vigorous, it ought to make a good market Daffodil. Last season the question was asked in THE GARDEN whether it would be profitable to raise sulphur-coloured Daffodils between *obvallaris* and *cemum*. This I have done, the progeny having a long trumpet and standing out boldly from the flower-stem in the manner of *obvallaris*. I include a bloom of the Irish form of Ajax *Telamonius*, which is distinguished by the unbroken trumpet. It is, I believe, found in two or three localities only in Ireland, from one of which I got my bulbs. I have never seen this variety in English gardens and am rather at a loss to account for its existence, but should imagine that either soil or climate has through a series of years acted on the original form. I should not suppose it to be a

seedling, for with me it varies considerably, a good many of the flowers occasionally reverting to the old form, whilst in some years nearly every bulb produces flowers with unbroken trumpets. It is, I believe, in a naturalised state in the vicinity of old monastic or castle gardens that this form has been found, and in soil of a semi-boggy character. This is what I have been told by those who have seen it growing, and every flower comes like that enclosed. When March and the early part of April are very fine, a large proportion of the flowers bursts, but in a cool, late spring like this nearly every bloom comes true to character. The pale coloured flower is from *obvallaris* and *cernuus*. We have many white-flowered Daffodils, but they are not quite so robust as might be wished, and are somewhat fastidious as regards soil. We want good white Daffodils that will flourish in any soil and that can be naturalised in the Grass or woodland—that are, in fact, as vigorous and reliable as the Tenby, Princeps, or Old Double. J. CORNHILL.

**Honesty.**—There appear to be three distinct varieties of this charming biennial, the

*Pelargonium Dr. Andrei.*

early crimson, the deepest coloured of all, the ordinary pale purple, and the white. Some plants will come among the ordinary purple bearing flowers partly white and partly purple, probably the result of crossing through insect agency, but anyone who desires to keep the varieties true to character should not save seed from such. I have grown plants of all the three varieties of *Honesty* for years, but I scarcely ever before saw them so much injured by frost as in the early part of this year; the plants appeared to be hopelessly killed and were little better than rotten stumps. Yet there was a reserve of vitality in them, and it was astonishing to see how they rallied and put forth new growth when warm weather set in. Patches of the three colours now in full bloom are very effective.—R. D.

**Christmas Roses.**—I have no doubt that the soil in which the roots are growing has much to do with the repeated failures of Christmas Roses in some gardens. I know a garden where some hundreds of plants, including nearly all the varieties, have been planted at various times, and in spite of the care bestowed in planting not one single clump is in a satisfactory condition at the present time. Not only have the plants been tried in various parts of the garden, but they have been planted in specially prepared compost in large tubs with similar results. In this case the roots are first affected, changing to a dark colour and finally rotting. The leaves next follow suit until

the clumps are wholly denuded. The soil in this garden is of a dark sandy nature. Very often where Christmas Roses succeed fairly well without special attention being paid to them they might succeed better by supplying them liberally with moisture during the month of May when new leaves are being made, should the weather be hot and dry at that time. I notice plants that make abundant leafage annually give a better crop of blossom than those which make hardly any new leaves. I find mulchings of freshly gathered horse manure beneficial if applied early in May.—E. M.

## STOVE AND GREENHOUSE.

### DECORATIVE PELARGONIUMS.

EXCLUSIVE of the zonal, nosegay and Ivy-leaved forms so often spoken of as Geraniums, the different Pelargoniums are for convenience sake divided into several sections, but opinions differ as to the place that should be assigned them, their parentage being in a very mixed state. At one time only the large-flowered or show section

distinct blotch and in others this spot was limited to the three lower ones. Some again were without any decided spot. A good example of these French Pelargoniums is that here illustrated—*Dr. André*, which is a very old variety, but still one of the best that we have. A quarter of a century ago the recognised sections into which Pelargoniums were divided consisted of show, French or spotted, and fancy, but soon afterwards the name of regal Pelargoniums was bestowed upon a group that sprang into existence about that time. The flowers of these regal Pelargoniums were large and consisted of an unusual number of massive petals, the earliest examples of them being *Captain Raikes*, *Queen Victoria* and *Beauty of Oxtou*. As this group became popular the term “regal” was applied to many that had no claim to the designation. Then a sensible suggestion was acted upon by many, and those sections known as French, spotted and regal were, in common with the popular market forms, all included under the head of decorative Pelargoniums, thus leaving only the show, fancy, and decorative groups. The best of these decorative varieties are of great use to the gardener who has to keep a structure gay at all seasons, their great variety in the form and colour of the flowers and other features rendering them as a group more interesting than a corresponding number of show varieties in which there is less variety in the shape of the flower and its markings. Pelargoniums, especially the decorative varieties, usually form a conspicuous feature at the Temple show, two of the largest contributors within the London district being Messrs. Hayes, of Edmonton, and Mr. H. J. Jones, of Lewisham. The plants are not remarkably large, for pots 5 in. to 6 in. in diameter, so popular with market growers, are the sizes principally used, and Messrs. Hayes have for many years been noted for the beautiful little flowering examples that they grow in pots only 4 inches in diameter. There are a great number of desirable varieties, but as tastes differ in this respect, a good plan is to inspect a collection when in bloom and make a selection therefrom. In selecting any particular variety, the habit of the plant should be especially taken into consideration. With the present wealth of varieties there is no need to grow plants of weak constitution. Some of the fancy varieties are decidedly pretty and bloom most profusely, but they are not grown to any great extent. H. P.

was generally cultivated, and the members of this group still hold their own. A good show flower is almost round, with the edges of the petals smooth. The two upper petals of these show varieties are blotched with a deep colour, often nearly black, and frequently to such an extent that they are almost entirely of that tint. The three lower petals are without spots or blotches, while in many cases the flower has a large white eye often spotted with violet. The individual blooms of the best show varieties are large and brightly coloured—indeed, some of the richest tints of all are to be found in this section; but in the case of the brightest-coloured forms few flowers are borne in a truss, and the constitution of the plant is, as a rule, weak, so that most of them run up tall and thin. This is to a great extent the result of continuous intercrossing. A decided break away from these show varieties was made forty years ago or thereabouts, when the French raisers sent a number of new forms to this country. Although the blooms did not conform to the standard of show flowers, yet the plants were free in growth, profuse in bloom and of good habit, in addition to which the individual flowers had in many cases the edges of the petals prettily crisped and undulated; the colour also varied, and in some cases each petal had in the centre a clear and

**Ivy-leaved Geraniums.**—These appear to be finding more favour for a variety of purposes in many gardens, but it is more particularly to their value for covering back walls of vinerias that I should like to draw attention. After having tried Roses, Figs, and almost all fruiting or flowering plants on these back walls none have proved so generally satisfactory as Ivy-leaved Geraniums. Roses are prone to insect pests, Camellias get troubled with scale, and seldom flower well under the shade of Vines. Figs are not very prolific in such a position; in fact, a long list might be given of plants that are practically a failure, but Ivy-leaved Geraniums are certainly an exception. In a range of three vinerias we have the back walls clothed with these plants in variety, and it is astonishing the quantity of flowers they give from the end of February to the middle of June. The only insect foe that ever appears on the plants is aphid, which sometimes comes soon after the Vines are started, but a good fumigation soon disposes of the enemy and we are not troubled with it again for the season. Some state that thrips attack the foliage, but since planting them nine years ago not a thrip has been discovered upon them. When the vinerias are cleaned and made ready for starting again, the plants are well cut back and some of

the growth removed entirely. No further labour is required beyond tying in a few leading shoots to cover the wall, all the other growths are allowed to hang down loosely, as they are less formal and do not give the wall a stiff appearance, and when in flower they present one mass of colour. By planting a mixture of varieties, arranged so that the different colours will have the best effect, a charming combination can be obtained. At the head of the list I place *Souvenir de Charles Turner*, as it is one of the best wall plants, being vigorous and very free, flowers large, deep rose, nearly scarlet, and of perfect form. *Louis Thibaut* is very free flowering and a good grower, flowers cerise in colour. *Kycroft Surprise* is a splendid variety, flowers of a fine salmon colour, trusses and pips very large. *Mme. Emile Galle* is, I think, the best white, the flowers large and freely produced. Other varieties could be named, but the above four have proved the best with me.—W. G. C.

**Malmaison Carnations.**—In a private garden in this neighbourhood I lately saw an excellent lot of the ordinary form of *Souvenir de Malmaison* Carnation. The plants are in 6-inch pots, are green as Leeks, with foliage down to the rim of the pots. They have been flowering since last November up to the present time, and will evidently continue to do so for a couple of months longer. They are the best lot of plants of the size I ever saw. It may be remembered that I have more than once expressed the belief founded on experience that the best results in the case of the *Souvenir* and winter-blooming Carnations are to be had from two-year-old plants. From plants layered the preceding summer and put into 5 inch pots early in the year one may get good blooms, but the amount obtained from the space is not nearly so great as can be had from older ones. The plants above-mentioned were put into the pots in which they are blooming over eighteen months ago. They have not run up leggy, but are comparatively dwarf, and carry about a dozen flower-stems each, the blooms opening well, without the objectionable eye that characterises this Carnation when the plants are not in good condition. They are grown in the open air all through the summer months. My impression is that only plants of this description are really profitable.—J. C. B.

**Calceolaria Burbidgei.**—Notwithstanding the fact that the raiser of this *Calceolaria* could never do much with it as a pot plant (as detailed in *THE GARDEN*, p. 306), each recurring season it is very fine at Kew grown in this way, and forms an ornamental feature in the greenhouse throughout the greater part of the autumn and winter. Of course, large pots are used, and the plant runs up to a height of 4 feet or more, but it produces a great number of stems and a very large quantity of blossoms. It is a useful subject where glass structures have to be kept gay at all seasons, and its soft yellow blossoms are quite distinct from those of any of its associates, which at that season of the year are none too numerous. Though this *Calceolaria* is readily propagated, yet, in common with its parents, it cannot be easily obtained from any dealers in plants; the reason given is that subjects such as this are sought after only by lovers of out-of-the-way plants; hence the demand for them is so limited that it does not pay to keep them in stock. This is in all probability correct, as, despite the great number of plants available for greenhouse decoration, the kinds grown in many gardens are very limited, the usual selection of *Fuchsias*, *Pelargoniums*, *Petunias*, *Heliotropes*, *Lobelias*, *Begonias* of all classes, and such things being, as a rule, very generally met with.—H. P.

**Carnation notes.**—The present is an anxious time with growers of tree Carnations, as early-struck plants in small pots will need attention in the way of repotting and staking, and there is usually at this season a press of other work. An extra effort, however, should be made to get them shifted before becoming pot-bound, or they are

liable to refuse to grow away freely and sometimes turn yellow and sickly. Before removing them I always like to fumigate slightly twice, giving the foliage a good syringing after each dose, as the nights are often cold all through May. I prefer keeping the plants in a very cool, airy house until quite the end of the month; I then stand the pots on ashes in frames, airing carefully at first, and in June drawing the lights off by day, tilting them up during wet weather. Towards the end of June the plants should be ready for their flowering pots and for standing out of doors in a sunny position on a bed of coal-ashes. Great care is needed at all times in watering Carnations, but more especially after potting and until new roots are working freely in the new soil. If wet weather sets in I sometimes turn the pots on their sides for a few days, as at this date, if the soil once becomes sodden the whole batch will be liable to perish. Good, light, friable soil suits Carnations best. I always use the trimmings of pleasure-ground walks and drives. This contains a good percentage of grit, and after having lain twelve months it is fit for use without any addition, save a little leaf-mould.—J. C.

#### GREENHOUSE ARAUCARIAS.

Of the numerous species of *Araucarias* that are in cultivation only one, *A. imbricata* (the Chilean Monkey Puzzle), can be considered hardy in this country, all the others requiring the protection of a greenhouse, and some of them are very popular for growing under glass. The most generally grown is the Norfolk Island Pine,

*ARAUCARIA EXCELSA*, which when fully developed will reach a height of 150 feet or more, and yet when not more than a foot high forms a beautifully symmetrical-shaped specimen; hence it is very popular for table decoration, for furnishing vases indoors, and such like purposes. Owing to its popularity considerable quantities of seeds have been imported within the last few years, so that it can now be obtained at a cheaper rate than was at one time the case, but for small specimens seedlings are not much sought after, as they are not so well furnished at the base as plants raised from cuttings. The cuttings, of course, must not be formed of the side-shoots, as they will never make a symmetrical-shaped plant, the leading shoots only being chosen for the purpose. Where this *Araucaria* is propagated in quantity old stock plants are usually kept for the supply of cuttings, that is to say, plants that have become bare at the base or outgrown the space allotted to them. If the tops of these plants are cut off they will usually push out two or three or even more leaders, all of which directly they are firm enough may be taken as cuttings. These stock plants will continue to yield shoots in this way to a greater or less extent for years, and in this manner a large quantity of healthy young plants may be obtained. The cuttings need to be put into small pots of sandy soil and placed in a close propagating frame till rooted. Given conditions favourable to growth and ample space for the development of the plants, they will form equally symmetrical specimens, whether a couple of feet high or ten times that height. Hence they are very popular for large conservatories, and with care may be kept in health for years in a large pot or tub. Individual plants of this *Araucaria* vary a good deal from each other in many particulars, and some well-marked forms are in cultivation. One variety, *glauca*, has the foliage of a rich glaucous hue, and when a good form is obtained it is a really striking plant. Another beautiful variety is *robusta*, and a well-marked one is *alba spica*, but as regards its beauty opinions vary. The young growth of this is white, changing when mature to green, but the entire plant lacks the vigour of the type, and is, generally speaking, as an ornamental plant inferior to it.

*ARAUCARIA BIDWILLI* (the Bunya-Bunya Pine of Eastern Australia) is a very distinct species, but

one not often met with, for in a small state it has a loose, ungainly appearance, at least in most instances, though occasionally a neater growing individual may be met with. The leaves are lanceolate, very sharply pointed, and of a deep glossy green colour. It is more fitted for large structures such as the temperate house at Kew, and under such conditions it forms a handsome dense growing specimen of the richest green. From 6 feet upwards, this *Araucaria* shows more of its true character than it does below that height.

*ARAUCARIA RULEI* is a beautiful and distinct species with wide-spreading branches and partially drooping branchlets. The leaves are thick and dark green, while the entire plant has a massive stately appearance. It is very beautiful when not more than a yard high, but is equally effective as a larger specimen. A thriving plant of this *Araucaria* always commands a good price. There is a variety of *A. Rulei* known as *elegans*, far more slender in all its parts than the type, but it is usually unhappy-looking and in no way desirable. Nearly allied to *A. Rulei* is *A. Goldieana*, whose foliage is more slender than that of *A. Rulei*, but intermediate forms are sometimes to be met with.

*A. CUNNINGHAMI*, one of the most useful timber trees of Queensland, has needle-like leaves as in *A. excelsa*, but instead of the branches being arranged in a regular frond-like manner as in that kind, those of *A. Cunninghami* are more tufted and clustered, thus giving to the plant altogether a more irregular outline, which is maintained when the specimen attains tree-like dimensions. It is more effective over 4 feet to 5 feet than it is under that height. One variety, *glauca*, is very attractive by reason of its silvery foliage.

*A. COOKI*, which is a native of New Caledonia, has the finest and softest foliage of any of the *Araucarias*, and it requires rather more care and attention than most of the others. The branches are numerous even on small plants, and well furnished with partially drooping branchlets, which in their turn are thickly clothed with short awl-shaped leaves. If this *Araucaria* is at all neglected, the foliage quickly acquires a yellowish hue, and it is then very difficult to restore it to its normal tint.

*A. BRASILIENSIS* is a common tree in some parts of Brazil, but it is very little grown in this country, its ornamental qualities not being of a high order. T.

#### KITCHEN GARDEN.

##### ROOT GALL IN TOMATOES.

We enclose a root of Tomato infested with elub. The plants have been put out two months and have been looking well until now. The plants flag during the day, and on examining the roots we have found them as per sample sent. Can you suggest a remedy?—HUBERT & MAUGER, *Gurnsey*.

\* \* A bad case of root gall, the same being caused by *Heterodera radicola*, a minute worm said to be allied to *Trichina*. When the roots are taken possession of by these much-to-be-dreaded nematodes, or eel-worms, and which serve not so much as a feeding as a breeding ground, they soon become badly swollen, ceasing then to fulfil their natural functions. It is during bright weather that evaporation of moisture by the foliage goes on the most briskly, and the roots failing to supply this in sufficient quantities, flagging and a general breakdown inevitably result. Once more the old saying, to the effect that prevention is better than cure, applies. In the case of plants so badly affected it is doubtful if a remedy can be effectively applied. What has done good service in the case of a form of eel worm that takes possession of the stems near the surface of the soil might well be tried, and this is phenyl phenol, or carbolic acid. I am using it by way of prevention, and have great faith in the preparation. Those who order several one-gallon drums of this can get

it from a chemist at the rate of 5s. per gallon, but a single one-gallon drum would cost more, or from 6s. to 7s. 6d. each. One pint of this preparation I find sufficient for one hundred gallons of water, and a thorough soaking of it is given before the soil is dry or soon after water has been applied. At this strength not a plant out of thousands has been injured, but, on the contrary, the plants are benefited by its application, a certain amount of nitrogen being present in the phenyl. It may be that two or three applications of this manifold disinfectant to the roots may restore them to a more healthy state and prevent a complete failure, but I should not rely too exclusively upon it, preferring rather to raise a fresh lot of plants with a view to having heavy late crops. In all probability the soil now occupied by the plants was similarly cropped last season, and trenching or the addition of so much fresh soil and manure would not have done anything towards getting rid of any eel worms left in from a slight attack last year. The tiny pest also seems to be most often present when much decayed vegetable matter, including rotten manure, is freely mixed with the soil, and the first attack in such cases is usually a very severe one. Drenching such soil with the diluted phenyl is an excellent preventive, but ought not to be wholly depended upon. If the soil cannot be fre-hened up by trenching and a free addition of fresh loam and fresh horse droppings rather than stale manure, pot culture should be resorted to for one or two seasons. Wholly changing the soil in a large house or several ranges of houses is a very expensive proceeding, but enough fresh soil can usually be looked up for several thousand 10 inch or larger pots, and under pot culture, accompanied by an occasional application of phenyl, nematode worms can be defied. The American remedy for the complaint is a thorough exposure of the soil, in and out of the houses, to the purifying influence of severe frosts. In Guernsey it is doubtful if enough frost is registered to have much effect upon insects or animals in the soil, especially if covered with glass. Last winter the soil in many Tomato houses was hard frozen, and was thus all the better for the exposure.—W. I.

**Early Cauliflowers.**—At p. 284 "E. M." advises Early London for early summer use. The Early London in a light soil I find is not of such compact habit, the head or flower opening quickly. It must not, however, be thought I do not advise its culture, as very likely "E. M.'s" soil just suits it. The Early London is closely allied to two varieties now less grown than formerly, the Stadtholder and the Walcheien, but of the three I prefer the last on account of its compact growth and the heads, being so much better covered with foliage, are whiter and closer. For first cutting in May to follow the late Broccoli I prefer the Dwarf Erfurt Mammoth, which turns in ten days or a fortnight earlier than the Early London, and is in my opinion of superior quality. The Erfurt is quite as hardy as the Early London, so is very suitable for autumn sowing.—S. H.

**Wintering Lettuces.**—At p. 272 Mr. Tallaek gives us sound advice as to wintering Lettuce. It is strange how different localities have fared with regard to the past severe weather. All my plants perished, no matter whether sheltered by glass or in the open. I must admit this is the first season I have lost the entire crop, and many large growers who had splendid beds of Hardy Hammer-smith—one of the very best winter Lettuces grown—are similarly situated. By sowing Veitch's Golden Queen indoors in February I am now cutting nice heads, small certainly, but valuable. This is one of the earliest varieties to heart in I have grown, being fit for use in eight weeks from time of sowing.—G. WYTHES.

**Notes on Spinach.**—In most gardens Spinach will have come in useful. Though cut up by the severe frost early in the year, it quickly recovered with the advent of warmer weather, and has supplied very acceptable dishes daily for weeks

In addition to the well-known Prickly or Winter Spinach, the Perpetual or Spinach Beet has done extremely well, and no doubt as the latter becomes better known it will be extensively sown for standing the winter, as it produces immense quantities of large leaves that cook remarkably well and are of very good flavour. When first I grew the Spinach Beet I was unfavourably impressed with it, as the foliage came white or nearly so, and a moderately sharp frost killed it. Several gardening friends had a similar experience. Fortunately, I got the true variety, and now I should be sorry not to have a good quarter in the garden. A new variety of Spinach sent out by Messrs. Carter, High Holborn, named The Carter, promises to be an acquisition for spring and summer work. Sown on a warm border immediately the ground would work freely after the frost, it came up quickly, and is now (May 7) supplying large thick leaves of fine quality, while the ordinary round or Summer Spinach will not be fit to pick for another fortnight, though sown under exactly the same conditions. Few crops pay so well for thinning and liberal manuring as Spinach. Many rows are over much sooner than they would be and produce a much smaller crop of leaves than would be the case if the plants were thinned out to about 6 inches apart in the rows, to say nothing of the favour the large leaves find in the kitchen compared with a multitude of small ones.—W. G. C.

**Mushrooms in fields.**—In face of the depression in the value of most crops and the great difficulty cultivators of the land find in making ends meet, it may perhaps be useful to draw attention to the easy manner in which Mushrooms can be grown on pasture land that is naturally adapted to produce this edible fungus. There are thousands of acres that would grow Mushrooms admirably, and prove a source of profit to the occupier without any loss or detriment to the Grass crop; in fact, if conducted as hereafter described, the Grass will be considerably improved, and yield more per acre than if not so treated. The first step is to procure good spawn that will run freely when placed in a suitable medium. The present is an excellent time to insert the spawn in pastures, breaking it into lumps about the size of a hen's egg; then raise the turf with a spade and place a lump underneath, about 3 inches or 4 inches from the surface. It is important that the soil and turf be made thoroughly firm again by well treading or beating down with the back of a spade, otherwise the spawn will not run well into the surrounding soil, and is liable to fail entirely. The distance between the lumps of spawn may vary from 2 to 6 yards apart each way; if the field is specially adapted for Mushroom growing the latter distance will answer very well. When the spawn has once got established the field may be expected to yield Mushrooms for years afterwards if given a dressing of 3 cwt. of agricultural salt at the end of March or early in April. As to prices, they will vary from 1s. to 2s. per lb. according to the earliness of the crop, and the returns per acre will also be ruled to a great extent by seasons, as very dry or very wet, cold seasons may cause the profits to be practically nil. However, as the first cost in spawn is very small, comparatively speaking, it is worth while risking the outlay, as the returns might be of the most gratifying description. Personally I have had both good and bad results, but, on the whole, the investment has proved a very paying one.—W. G. C.

**Early Peas.**—These will be none too early this season. The early Peas are often planted on sloping, warm borders, and as we have had little rain to assist growth, it will be well to give moisture to plants that were raised under glass, as these soon suffer from drying winds and little moisture. I find the dwarf growers are much benefited by a light watering early in the day when the weather is warm. The plants should also get supplies of food at the roots in the way of liquid manure, or a good fertiliser used in a liquid state. Those who grow some of the second early varieties would do well to top them when

the haulm is from 2 feet to 3 feet high. I grow some of the 5-foot Peas and top at 2½ feet, with excellent results. The haulm branches out freely and there is a much heavier crop, and though the plants occupy about the same space as the dwarf kinds, there are much finer crops, which are nearly as early as in the case of the small growers.—S. H. B.

**Too many varieties of Potatoes.**—I was recently talking to a young gardener who told me that this season he had no less than forty varieties of Potatoes, and only six last year. I ventured to advise him to keep to the smaller number if they suited the soil and cropped well. A small selection grown in quantity is far better than a few of each, with no knowledge of their eating or keeping qualities. As soils vary so much and affect the quality, it is well to grow kinds which give the best results.—G.

**Variegated Kales.**—The collection of Kales in many colours impossible to describe sent by Messrs. Sutton to the meeting of the Royal Horticultural Society on April 23 was most instructive. These Kales are highly ornamental and if so many varieties can be staged after so severe a winter, it shows they must be very hardy. They belong to the Scotch section, the hardiest kind of Kale grown, and they answer two purposes, being good for decoration and for cooking, as when cooked they lose their colour and are equal to the green varieties. These Kales were highly commended by the society for their beautiful appearance and good keeping qualities. Early in May is a good time to get a stock for next winter; it is well to sow thinly and plant on open borders. The variegated varieties are not so strong-growing as the fine curled green varieties.—G. W.

**Seakale not forced.**—This is so often forced that a late or May supply is at times overlooked. Few vegetables are so easily grown as Seakale when the roots are only required for late cutting in the open ground. The chief difficulty is the blanching, as if not well covered, the tops soon force their way above the soil and become green. I get a valuable supply from the late roots covered with fine ashes to keep slugs away, and then banked up with soil. To do this it is necessary to have plenty of space between the rows. I usually cover with from 15 inches to 18 inches of leaves, which did duty the previous year in forcing Asparagus. The Seakale is grown close to the pits and is covered in December. Two-year-old roots are best, being stronger. The Kale produced in this way is delicious.—G.

**Coarse Salsify and Scorzonera.**—Many fail with these crops through too early sowing. From the end of April to May 10 is a suitable time to sow, and if room cannot be afforded for both these vegetables, I would advise the Salsify, sowing the improved variety, the Sandwich Island Mammoth. This is far superior to the older kind, producing clean straight roots much larger in size. The best Scorzonera is the new Large Russian, a very fine root of excellent flavour. These two vegetables are most valuable at the present date, when there is but a limited list to select from, and keeping so well into the spring makes them more valuable. They grow so quickly in warm soils, that if sown too early I have seen the whole crop lost by running to seed, and the roots fork so badly that they are not worth storage. This is readily prevented by late sowing on land which has borne a crop. If given manure when sown the roots are nearly useless, forked roots not keeping well.—W. S. M.

**Borecoles and their value.**—The great value of Borecoles in such a winter as we have recently experienced should make them greater favourites than ever, as in many gardens the Scotch and hardy varieties are the only vegetables left to give the supply for some weeks. The Borecoles have passed through the winter with less injury than any other green vegetable with the exception of Spinach, thus proving their hardiness. It may be suggested that those who have not lost their crops have been favoured in the way of less frost, but I do not think such is the case, much depend-

ing upon the state of the plants when put out, and, of course, to a certain extent upon variety and position of plants. I had 36" of frost, quite enough, one would think, to test the hardiness of any vegetable crop and most of the Scotch Kales, and such kinds as Buda or Asparagus, with Cottager's and the newer Arctic varieties, were uninjured. Sow very thinly on good land at any time from the end of April till well into May, as when raised too early the plants, when crowded, have not that dwarf hard growth which resists extremes of weather. For early supplies it is much better to transplant and thus promote a dwarf growth. Those with plenty of land at their disposal may with advantage sow seed very thinly at any time in May in drills 2 feet apart, thinning the plants to 18 inches in the row and planting out the thinnings thickly for the earliest cutting in the shape of dwarf greens. The Dwarf Green and Late Curled, with the varieties named above, are the best.—G.

**Fish manure for Asparagus in spring.**—Now is an excellent time to dress old beds with the above manure. I do not think any time of the year so good as May, and if we get dripping weather the fertiliser is washed down and acts at once. It may be thought that salt is equally efficacious, but it is not. I admit salt answers well on light soils, but with heavy rains or little sun the beds are kept so cold that it does not feed in the way fish manure does. On heavy soils salt may be given two months hence much better than at the present time; indeed, in my opinion, it is best applied then in any kind of soil.—W. S.

**Potato Sandringham.**—A gardener who annually aims at producing frame Potatoes at an extra early date recently informed me that the earliest variety for this purpose he had ever tried was Sandringham. Not only, added he, is it early, but it is a fine cropper, far superior in the latter respect to Sharpe's Victor, which only produces from four to six tubers at a root. I shall give Sandringham a trial next season, and it might be well for others needing early supplies to do the same, as my informant has had great experience in early Potato forcing.—J. C.

**Mushrooms.**—Those who have a house in an extra cool position will do well to use special care to prevent the young Mushrooms from turning black and becoming useless. Of course, no fire-heat must be used, but coolness must be further encouraged by throwing open all the ventilators at night, closing them again at daybreak. Apply tepid water to the beds as required and damp floors and walls daily. The Mushrooms should not be left on the beds a moment longer after they are fit for use, as they will keep much better if placed in a cool cellar or store house.

#### OPEN-AIR TOMATOES.

MANY err in sowing the seeds of plants intended for planting against outside walls too soon; consequently the plants become pot-bound and the wood hard long before the weather is fit for transplanting them. Where fear of this evil exists, it will be well to pot the plants on, as they will soon root round the balls, and may then safely be kept in frames or a cool house for another fortnight if need be. I have a small batch of plants brought on in advance of the main lot, and finally potted into, say, 10-inch pots with a view to sinking them into the border of a south wall. This in warm districts may be done at the end of this month, and if after the cavity has been taken out a good thickness of rotten manure is placed in the bottom and the hole in the pots made much larger, the roots will soon push through the bottom, and, taking advantage of the rich food provided, will grow away freely and fruit well. The pots should be sunk just below the ground level, so that a liberal mulch of short manure can be given in order to conserve the moisture and also to encourage surface roots. Bearing in mind the root-restriction this batch is subject to, water must always be supplied with a liberal hand, and when sufficient fruit is set, the leading growths must be

pinched, all side laterals being likewise kept off. Of course some method of protection must be devised, or cutting winds and even late frosts may cripple the plants. A very good plan is to put wide boards on either side of them and to place some Yew or Laurel boughs in front. These admit sufficient sun-heat and light, and yet screen the growth from harm. Those plants which are to form the principal batch for outdoor work, and which will not be planted out until the beginning of June, must be gradually hardened off in frames, being fully exposed on fine sunny days, as in the case of the above named lot. If any signs of exhaustion show themselves, a good surface dressing of loam and artificial manure must be given. It is well to prepare the stations under walls for Tomatoes some time before actual planting, so as to give them an opportunity of settling. There is then less fear of excessive evaporation, and the plants generally go away better than when put into newly-disturbed soil. When preparing, add a little good loamy soil and rotten manure, mixing it thoroughly and making it firm. I should here add that on the plants that are to be plunged a few fruits may set while in the frames. These should not be removed, as they will swell off in spite of the removal to an outdoor temperature, and, ripening extra early, prove most useful, especially where no indoor Tomatoes are grown.

J. C.

**Outdoor Mushroom beds.**—Some weeks ago I recommended those who need a constant supply to make up a bed in the open air to yield during the latter part of May and June. Where plenty of good horse manure is at command, now is a good time to commence, saving the material for a second open-air bed to afford Mushrooms during July, August, and September. As I stated before, where there is a difficulty in securing sufficient manure for a full-sized bed, a percentage of good Oak or Beech leaves and a few barrowloads of rough fibrous loamy soil may be added. In preparing it, care should be taken not to expose it to the action of the sun and wind, as these agents not only dry out the goodness, but necessitate the use of water at making-up time.—C.

**Summer Radishes.**—A north shady border or one partially sheltered by trees will grow the summer crop, but much may be done by selection of varieties, and by this means provide a long supply. For summer the Red and White Turnip varieties are good, also several of the olive-shaped kinds. For later sowing the China Rose is a very fine August and September variety, and for the months named may be sown on a border facing east. For later use the Black Spanish or Winter Radish is the best.—G. WYTHES.

**Potato Sharpe's Victor.**—I am not so sure that "J. C." (p. 284) is quite right in his estimate of Victor, as he says he thinks it requires a somewhat strong soil. This makes me think he cannot have the true variety. I have had two varieties, one much rounder and greatly inferior to the other, yielding about two large or medium-sized tubers with a mass of small worthless ones; whereas the true variety has a flattened oval tuber, is a good cropper, and is specially good for frame culture. I have been so successful with this variety, that I look upon it with special favour, its earliness combined with good flavour making it most valuable as a first early. I have grown Ringleader, but prefer Victor for forcing. I cannot see why Victor should fail on light soils. Our soil is on gravel, and the lightest I have ever had anything to do with, and Victor does well. Under field culture I saw this variety in splendid condition in Scotland in 1891.—G.

**Celery Man of Kent.**—This variety will keep sound well into May. The severe winter upset all our calculations as to a regular supply, and protecting large breadths was out of the question. I did not expect to see any living roots after the thaw, but the above variety and Standard-bearer were the only two sound varieties left, the Man of Kent being firm and very little decayed. It is not coarse, the colour bright red, the flavour very

sweet and nutty. It does well in poor land. The leaves are much cut. I did not sow till late, and therefore did not get large plants, but perhaps that was fortunate, smaller plants wintering best.—W.

#### VEGETABLE MARROWS.

It is not in every garden that either room or time can be spared for the culture of extra early Marrows in frames on warm beds. There are few, however, who do not grow for a supply say at the end of July and through August and September. Where hand-lights are at command, also a good supply of leaves and short stable litter, I would advise taking out a trench, say 6 feet in width and 2 feet deep, and after well mixing and treading in the fermenting material, place the thrown-out soil on the surface, so that when all is finished the ridges will be a foot higher than the surrounding ground. Then place the hand-lights in position, allowing a distance of 6 feet between each, place therein a little fine semi-dry loam, and sow the seeds at once. As thinning can be practised to any extent after the plants are up, insert plenty of seed, and keep the tops on the lights till growth is seen, after which arrange them crossways on fine sunny days to admit air and strengthen the plants. A sharp eye must be kept for slugs and snails, as they very frequently abound in numbers in the leaves forming the bottom heat, and come forth at night to their destructive work. Prevention being better than cure, the surface soil amongst the seedlings should be freely dusted over with wood ashes and soot in equal parts once or twice a week until the plants grow out of harm's way. Some growers prefer a position partially shaded for Marrows, but, our summers being uncertain, the best position is a sunny one, mulehing being resorted to just as the plants are coming into bearing, should exceptional solar heat and absence of rain necessitate it. Where Marrows are grown minus bottom heat the seed should be sown in small pots, and the plants receive one good shift before finally transplanting them to the open beds. Bring them on from the start in a cool atmosphere—a greenhouse temperature is the best, and that of a frame for a fortnight previous to planting. In the meantime small mounds should be prepared by placing good loamy soil on the top of a few leaves. The addition of much manure is not advisable, as it often induces a rank growth prone to disease. The old plan of planting Marrows on the summit of manure heaps is not a good one by any means, as, independent of encouraging disease, which it certainly does, the flavour of the Marrows when cooked is often strong and objectionable. In addition to the ordinary varieties, the Custard Marrow may now be sown, this being preferred in some places before all others for the dining room. Ground vineries afford capital protection for transplanting Marrows, and amateurs and others who have no means of glass shelter must provide screens from cold winds by day by surrounding the plants with Spruce or Laurel boughs, and placing inverted flower-pots, buckets or baskets over them at night for the first fortnight. The third week in May is a good time for planting where only this partial shelter can be given.

J. CRAWFORD.

**Early Tomatoes.**—These will now be furnished with numerous clusters of fruit, the most forward of which will already be on the point of colouring. As, however, in most cases a good length of trellis has yet to be traversed by the leading shoot and a corresponding number of flower trusses has to form, great care in regard to watering, airing, training and fertilising will be necessary for some time to come. During dull, humid weather plants growing in heavy, old-fashioned houses are at a disadvantage, the trusses that form being weak, and in many cases the flowers fail to set well. Under such circumstances it is a great mistake to sprinkle floors and stages at any time of the day; rather let a gentle warmth circulate round the hot-water pipes and keep the

75 - GARDEN  
MAY 18 1907

ventilators both at the top and bottom of the house open half an inch. All side laterals must be removed as soon as formed, their retention being a double evil, first by robbing the main growth of sap, and secondly, by causing a check by being suddenly removed when of large size. Another cause of Tomatoes failing to set and, indeed, of becoming generally unhealthy is watering with water fresh from a cold well. This gives a check to the roots, and the whole plant is correspondingly affected. Where new roots show themselves on the surface of the balls, 1 inch of fresh compost should be given, but manurial mulchings should not be applied at present, or indeed until a full crop of fruit is set and swelling. The use of the syringe in Tomato culture is productive of much mischief, yet how many practise it daily. Some growers abandon the use of fire-heat at a certain date, say the first week in May, the result being that a low night temperature quickly induces mildew and all its attendant evils. Ripe fruits should if possible be gathered before they commence to crack, as if stored in any place in the least damp, mould sets in in a short time.

**Ellam's Early Cabbage.**—This has stood the severe winter well and is now turning in freely, not one plant in a hundred having run. I do not know of a hardier variety. I have plants in three sizes, and the same remarks apply to all. At one time I feared I had lost the larger plants, but though the large leaves were all destroyed, we have had such genial weather and growth has been so rapid, that the plants have made wonderful progress and well repaid for any extra attention given them in the way of liquid manure or guano. This is not a good Cabbage for spring sowing.—G. W.

## GARDEN FLORA.

### PLATE 1014

#### ACIDANTHERAS.

(WITH A COLOURED PLATE OF A. BICOLOR.\*)

There are in all about seventeen species of *Acidantha* known to botanists, but only one besides the species here figured has been introduced to cultivation. The genus is purely African, and the species are represented most abundantly in Cape Colony, although outlying species occur as far apart as the mountains of Abyssinia, Sierra Leone, Kilimanjaro Mountain, &c. It is from these warmer, more northerly regions that the two cultivated species come, but in each case at several thousand feet altitude. The *Acidanthras* belong to the Iris family, and form a connecting link between *Gladiolus* and *Ixia*.

The species represented in the accompanying plate is a native of Abyssinia, where it was collected by Dr. Schimper, and described as long ago as 1844. It is of similar habit to a *Gladiolus*, and produces long arching leaves in two opposite rows from a roundish flattened corm, which is covered with matted fibre. The flowers, somewhat loosely borne on a spike 2 feet to 3 feet high, are pendulous. The perianth has a tube 4 inches to 5 inches long divided at the top into six segments, which are about 1½ inches in length and overlap each other. The flower is creamy white, with a broad, somewhat triangular patch of purple at the base of each segment, and is delightfully perfumed, more especially towards the latter part of the day. This plant has flowered at Kew on several occasions and is grown there in an unheated frame, planted in loam and silver

\* Drawn for THE GARDEN in the Royal Gardens, Kew, by H. G. Moon, July 12, 1894. Lithographed and printed by Guillaume Severeys.

sand. According to *Garden and Forest*, it is in the neighbourhood of New York grown in tubs, which are stood out-of-doors in summer, being taken indoors for autumn flowering. The other species in cultivation,

*A. EQUINOCTIALIS*, is one of more tropical character. It is a native of the Sugar-loaf Mountain, in Sierra Leone, where it was discovered by Mr. Scott-Elliott. Corms collected by Captain Donovan reached Kew about two years ago. It is described as growing "in the crevices of bare gneiss rocks in open spaces in the bush at 3000 feet altitude." It is nearly allied to the species here figured, and may possibly be a stronger-growing, more tropical form of that plant; it is, indeed, the finest of all the known *Acidanthras* both in its stature and in its flowers. Although it was only brought to the notice of the present generation of gardeners as lately as 1893, it appears to have been known forty or fifty years ago to Dean Herbert either as a cultivated plant or in a dried state, for there is in the Lindley Library an unpublished drawing of it made by him. It flowered at Kew towards the end of 1893, and has recently been figured in the *Botanical Magazine*, t. 7393. The stems are 4 feet in height, the sword-shaped leaves being 18 inches, sometimes more, in length. The flowers, as in *A. bicolor*, are borne loosely, and about half-a-dozen occur on the spike. The tube of the perianth is 6 inches long and the expanded portion 3 inches in diameter, with a crimson blotch at the base of each segment. This species requires considerably warmer treatment than *A. bicolor*, and has at Kew been found to succeed best as an intermediate stove plant. W. J. B.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**SOWING RUNNER BEANS IN THE OPEN.**—For those who require extra early pickings of Scarlet Runners I advised sowing some seed in boxes or pots and placing in warmth till up, the same being transplanted after due hardening. Now, however, in all gardens and soils the seed may be put into the open ground. It must be borne in mind that this section is very prone to decay if deep sowing is practised; 3 inches is quite deep enough for the drills, and on strong retentive soils a little artificial compost should be placed in them previous to sowing, and the drills finally filled up with the same. Allow plenty of room between the rows; where ground is plentiful from 9 feet to 10 feet is none too much. To make the most of the crop, tall, slender poles 12 feet high may be used, as the higher the haulm ascends the better the yield, and the crop can be gathered by the aid of steps. Where ordinary Pea rods are employed the growth when healthy often outgrows these supports, and, falling down, forms a complete thicket, into which neither air nor sun can penetrate; consequently the gatherings are very unsatisfactory. It is astonishing for what a length of time Runner Beans can be kept in a bearing state by allowing plenty of room in all directions and by keeping the pods from becoming old, and thus distressing the plants. Nothing pays better for good mulchings of rich manure followed by copious watering with farmyard liquid. Especially is this needful when many small pods and numerous bloom-trusses have formed. When sowing, always provide for possible blanks in the rows by sowing small patches of seed here and there at the ends of the quarters. Beware of slugs and snails, as I know of nothing in the kitchen garden more cherished by these pests than Scarlet Runners.

**JERUSALEM ARTICHOKE.**—If planted at the time advised these will now be advancing rapidly, and, as in the case of Potatoes, several growths

often issue from one tuber, due thinning of these is necessary. Go over the bed and reduce them to one for every 9 inches or a foot. If the Dutch hoe is now put through the rows, weeds will be destroyed in their infancy, and once the Artichokes make a foot of growth, weeds will stand but little chance of thriving amongst them. Artichokes are often planted in out-of-the-way corners where, being out of sight, they are out of mind, and weeds are often allowed to smother the plants in their infancy.

**SPINACH.**—From now onwards all sowings which may well be made fortnightly will do best in a cool border under an east or even a north wall. Here Spinach not only does better, but lasts much longer in usable condition than when exposed to the sun. Use the large-leaved *Victoria*, this being more robust for hot weather and more juicy and highly flavoured. Spinach responds quickly to an application of artificial manure, and if this can be given in showery weather, so much the better. It is a good plan to put it on the surface just after the first general picking has been made; the secondary growth is thereby improved, and running to seed hastily prevented. Allow plenty of room between the rows, and thin out the plants to 9 inches apart when the first pair of rough leaves have been made. Earlier beds now exhausted should be cleared off without delay, as, besides impoverishing the soil, the rain is kept from penetrating the surface.

**PLANTING SPRING ONIONS.**—Where seed of any special variety for producing large exhibition bulbs was sown early in February, and the plants have been treated according to advice given from time to time, planting out into the final rows may now take place. Presuming the ground was extra well manured and has lain for some time, all that is necessary is a thorough treading and raking of the surface. Water the young plants well the day before planting and remove them carefully with the point of a label, preserving all roots intact. In planting do not use a dibble, but a small hand fork, making cavities sufficiently large to admit all the roots, which should be spread out like the extended fingers of a man's hand, a little soil being placed over them to keep them in position till planting is completed, when a little more may be added and the surface made very firm. If the soil is at all light and fully exposed to the sun, as it ought to be, mulching will be necessary when the Onions get into full growth, and frequent broadcast sprinklings of soot should be given to keep away the Onion maggot. Liquid manure of good strength will also be necessary if large heavy bulbs are expected.

**THINNING SPRING ONIONS.**—Where the seed of Spanish and other early varieties was got in in good time, thinning will now be necessary. I do not, however, advise giving the final thinning just yet, as sometimes after cold rains the seedlings die off in great numbers. On the other hand, if thinning is deferred till the Onions are 4 inches or 5 inches high, the whole of the ground is loosened to such an extent, that those left fall about in all directions, and never do so well as when erect and firm. Rather than snap them off by pulling, use a pointed stick, with this giving a gentle leverage. Partial thinning completed, run the Dutch hoe through the rows and give a dressing of soot, as advised for the planted-out ones. The final thinning may take place in about three weeks' time. Where the small silver-skinned varieties are in request for pickling, the present is a good time to sow them. When up, thin only slightly, as they are sure to grow large enough by September.

**PARSNIPS.**—The earliest rows now require thinning, and with these also moderation at first is advisable, as cold winds may bring fly, which soon distigures the rows if not detected at once.

**LETTUCE.**—From now till earthing Celery commences there is no better place for growing Lettuce than the spaces between the trenches. Draw out slight drills the day before and water them well; the young tender rootlets then go into moisture at once, and go away quicker and better than when planted into dry soil and not watered

for some time after. For fortnightly sowings from now until September the Alexandria Cos is unsurpassed, and for those who require a good Cabbage variety I cannot name a better than Daniels' Continuity. One advantage this Lettuce has over all other Cabbage varieties is its non-liability to run to seed. Its firmness and quality generally also are very conspicuous.

**EARLY BROAD BEANS.**—Where these were planted out of pots and boxes and are now from 1 foot to 18 inches high, they may in exposed gardens fall victims to black fly. Immediately this pest is detected the points of the shoots should be dusted with tobacco powder and afterwards syringed with clean water. If this precaution is not taken, growth may be altogether suspended and the crop lost. A little soil should also be drawn up to the stems on either side of the row, and in the case of single rows, a few branches placed at intervals close up to the Beans and in a slanting position will keep them from falling about.

**SEED BEETROOT.**—Roots planted in March are now growing freely. If the centre growths are intact, all side growths must be removed, but where the crown growth died back in winter three side growths only should be selected. As soon as 1 foot high, stout stakes must be placed to each root and the growths tied to them at intervals. The same attention must be given to seed Onions, or winds will be liable to snap off the growths. J. CRAWFORD.

#### HARDY FRUITS.

**APRICOTS.**—These will claim first attention, and I regret to observe they have not passed through the winter as well as one could wish. Many trees show more decayed wood than usual, some of the centre branches having failed to break freely. These should now be removed. The shoots should be regulated as much as possible to fill up these gaps, and thinning of the fruit should be proceeded with. It is not wise to defer thinning, as even at this early date it is soon seen which will take the lead. Those who can lay in plenty of wood of each season's growth will find the trees are less troubled with disease, as young wood induces the formation of roots, which if kept near the surface by supplies of food in the way of moisture and liquid manure will furnish good crops and wood to replace that which decays. In thinning the fruits it is well to pay attention to useless growths, and by stopping throw the sap in the direction required. The roots should be examined, and if at all dry, water should be given. I am aware it is rather too early to advise watering, but much depends upon the state of the soil and the position of the trees. I have in a light soil found it necessary to water, and shall shortly mulch with short manure, the trees being much exposed and on a sloping bank with a gravelly subsoil. Of course, trees in better soil with ample depth will need less moisture, and the mulching may be deferred for a time.

**PEACHES AND NECTARINES.**—These, except in very late districts, should now be freely exposed. Disbudding will now need almost daily attention. I find it best to go over a portion of the trees daily. Disbudding is very soon understood after a little practice, and may be done by anyone interested in the work. So far the trees are remarkably healthy, and in this district have set very heavy crops. The weather having been most favourable very little protection was needed. In disbudding it is well to bear in mind the age of the tree, the number of fruit it will be allowed to mature, and other details. Do not crowd the wood in any way, but concentrate the energies of the tree to the growths required for extension and to produce fruiting wood next season. It often happens that some of the finest fruits set close to the nails and are injured if these are not removed. Shoots with fruit at the base should not be entirely removed, but pinched at the fourth leaf from the base. In disbudding, sufficient shoots should be left to furnish blanks on the wall. Any branches that show signs of canker or decay

should be removed, as these will not thrive, and it is an easy matter now to fill up any blank spaces with new growths. It is well to remove the superabundant fruits as early as possible. This can be done when regulating the shoots. The American varieties advance so rapidly up to the stoning period, that if thinning is at all delayed the trees soon suffer, the fruits drop, and what are saved are not the best. Should green-fly attack the young growths, it is well to syringe freely with weak tobacco water, or, what is better, give daily syringings with clear water, only using the tobacco for badly infested trees, and then a weak solution, as insecticides at these early stages of growth are not advisable. Some varieties mildew badly. As this pest spreads rapidly, it is well to use flowers of sulphur freely over the affected parts, keeping the foliage dry for a short time afterwards.

**CHERRIES** have set splendidly. They require much the same treatment as Apricots as regards mulching and moisture. The roots being close to the surface and the fruits soon stoning require much moisture at this stage, dryness at the roots being the forerunner of black-fly, a pest difficult to dislodge. It is scarcely necessary to remark that thinning is not required at this stage, as so many fruits drop before they stone. Many trees get crippled by crowded growth. All foreright shoots should be removed as early as possible, but should the cultivator require fruit from spurs on the main branches, it is best to select the side growths. These, being closer to the wall, get more protection, and at this date should be stopped freely for the purpose named, rubbing off any prominent forerights or shoots not required for the extension of the trees, as the more these can be encouraged the better, if wall space permits of extension. Cherries on light soils will repay an early mulch. I find cow manure in a light gravelly soil very good, and if at all fresh it is mixed with spent Mushroom manure, and thus keeps the roots from becoming dried up. Such kinds as Early Rivers, Frogmore Bigarreau and Governor Wood mature so quickly, that there should be as little delay as possible in mulching, syringing freely during the next few weeks to prevent aphides and assist the swelling of the fruits.

**PLUMS ON WALLS.**—These trees in some soils soon lose the bright, fresh appearance they have at this date, and become a prey to aphides. In such soils early mulching and frequent syringings are necessary, and the stopping of useless growth and the removal of foreright and crowded shoots should claim attention. The Plum brought on slowly under glass grows much like other fruits, showing that where due attention is paid to the wood there is a good return. Lay in plenty of fruiting wood for the next season, as much of the bearing wood may be cut away after the fruit is gathered. I have stated that the trees soon get sadly disfigured by aphids, and as this occurs at a busy season, it is well to be supplied with materials that will effect a speedy removal. I find quassia extract one of the best and safest insecticides. It does not injure the fruit, and is of special value for Plums and Cherries, but should not be used when the fruit is colouring.

**CORDON APPLES AND PEARS.**—The lateral growth of cordon trees should be stopped now while it is tender. It is far better to use the finger and thumb freely than the knife later on. Many useless shoots may be rubbed clean off, others pinched to form spurs, and the main or best leading shoot should be selected to form the leader. Young trees are this season showing much bloom, and it may be necessary a little later to thin severely. I am aware that Pears often shed their fruits badly in their early stages, but it often occurs owing to the trees being so heavily laden that the roots cannot find food for the same.

**NEWLY-PLANTED FRUIT TREES.**—In some districts trees were planted late owing to the severe weather, and will thus need more than ordinary care. An early mulch of short manure with occasional supplies of water should be given to these. It is also necessary to give the autumn-planted

trees the necessary moisture, as owing to the protracted frost the trees are unable to bear extremes of any kind. From such it will be well to remove the bloom, as it tends to weaken the trees. Against walls newly-planted trees such as Peaches and Nectarines were longer than usual in breaking, and on dry soils will be benefited if syringed over frequently. If the trees break too freely in one place reduce the shoots as soon as possible, so as to get the foundation of the tree laid and fairly started. Remove useless shoots at the base first and pull out foreright shoots at the earliest moment to induce stouter side growths, which are required for training or nailing in. Trees of the varieties named which are of fair size and inclined to make vigorous growth should be allowed to carry a light crop of fruit in order to check grossness.

**RASPBERRIES** have suffered severely. The hot summer of 1893 was not a favourable one for these, and the plants had only just got into condition, having made a late sappy growth, which was cut down by the arctic weather in February. Much may be done to help the canes by cutting down to a live portion any that are badly crippled, only allowing four to six growths from the base. The usual practice is to allow more and to thin to the number named after the fruit is gathered. Raspberries will now require to be mulched if the soil is light, and good manure should be used for the purpose. Newly planted canes that are breaking badly or only at the top should be cut down to within 6 inches of the soil and new growth from the base encouraged.

**STRAWBERRIES.**—These started very feebly, and are not nearly so well furnished with bloom-trusses as usual. This need not cause any alarm as to the crop, as a certain number of fruits well developed are preferable to a mass of small ones. Last season the early fruits got a severe check by frost at the end of this month. Though Strawberries will be later this season, it is well to be prepared for emergencies. Such a material as litter in a dry state is of great assistance to ward off frost, and as only limited areas can be covered, it is well to select the most promising or young plants. The mulching of the plants will now require attention. A double use may be made of the mulch. If the mulch is straw manure, the straw will be cleansed by heavy rains and ready for the fruit. It may also be turned to good account on frosty nights by lightly covering the bloom if lifted lightly with a fork. Before applying any mulch, hoe lightly between the rows, doing the work in bright weather. Apply food if necessary in the way of liquid manure, soot, or other fertilisers, but be careful to keep them clear of the plants. Young plants wanted to produce runners for forcing should have the flower-trusses removed to induce the formation of runners.

G. WYTHES.

#### TREES AND SHRUBS.

##### RHODODENDRONS AND THE FROST.

It often surprises me that the Pontic Rhododendron is so largely planted in gardens when many of the choice named varieties, hybrids of the much hardier and more vigorous catawbiense, are, to my mind, incomparably more beautiful. Out of one hundred and one different varieties in my garden I have lost remarkably few during the severe frost, although my position is rather low, and we had the frost in the near neighbourhood down to zero for several nights consecutively. Those that show signs of the severest punishment are mostly plants moved in the autumn, which possibly had not got well hold of the soil before the frost came. Baron Schröder, Odorum, Sun of Austerlitz, Broughtoni, and some choice unnamed seedlings from Loquendum, with long finger-like leaves, have been the hardest hit, but, so far as I can judge, more than ninety varieties out of the one hundred and one are practically uninjured, whilst the Laurel, the Privet, and some of the varieties of

Berberis are either killed outright or greatly damaged, forming a terrible eyesore in their present condition. It is, therefore, clearly demonstrated that the "queen of flowering shrubs," the Rhododendron, is far preferable as a hardy evergreen for our English climate than the uninteresting and apparently inevitable Laurel and Privet. As a fine foliaged plant the Rhododendron presents as much beauty, if the right sorts be selected with that object in view. Take the foliage, for instance, of such varieties as Joseph Whitworth, Charles Dickens, Lord Palmerston, Mrs. John Waterer, William Cowper, Sir Thomas Sebright, James Mackintosh, and Everestianum; it is beautiful all the year round, but add to this the blaze of colour of the choicest varieties when in bloom, it is amazing that the hardy Rhododendron is not more extensively planted. To those who may be interested in procuring a few of the very grandest varieties of hardy Rhododendrons—whether new or old—in cultivation, and who do not care to wade through nurserymen's bewildering catalogues, I would suggest a trial of the following twenty kinds as almost certain to give satisfaction in their respective colours if properly planted and attended to. If the former is well done, they do not require much of the latter, beyond well watering and syringing just when they are coming into bloom. Baroness L. de Rothschild, superb conical truss, brilliant scarlet, with lighter throat; Mrs. John Penn, salmon-pink edges, with waxy cream centre; Helen Waterer, white centre, with most brilliant scarlet edge; Kate Waterer, rose-crimson, with yellow centre; Lady Eleanor Cathcart, salmon-pink, finely-marked, very beautiful, but shy bloomer; Mrs. R. S. Holford, superb truss, salmon-pink; H. W. Sargent, dark velvety crimson; James Mackintosh, rich velvety crimson, fine truss, and splendid foliage; Michael Waterer, an old favourite, bright scarlet, rather poor foliage; Marchioness of Lansdowne, light red, intense maroon blotch, very fine flower; Marie Stuart, lovely shade of rose-lilac, with intense purple blotch, splendid truss and habit, flowers as beautiful as an Orchid; The Queen, one of the most beautiful whites; Lady Grey Egerton, purely white, magnificent truss; Sir T. Sebright, metallic bronzy purple, free and long bloomer; Joseph Whitworth, dark maroon, beautiful flower and foliage; Martin Hope Sutton, brilliant dark scarlet—if perfectly hardy, one of the finest in cultivation; James Marshall Brooks, scarlet, with a curious mossy bronze eye; Broughton (or Lord Palmerston), very similar, but not synonymous, grand trusses, bright pink, fine foliage; Frederick Waterer (or John Walter), different habit and foliage, but very similar flowers, bright scarlet, perfect trusses; Sigismund Rucker, rich magenta-crimson, with a black intense blotch. It would be easy to add twenty more almost as good as the foregoing, but it would be hard to name twenty better. When varieties such as those enumerated cost very little more than the ordinary ponticum, it is strange that they are not more extensively planted.—GEORGE BENNINGTON, *Bush Hill Park, Enfield, in Field.*

**Spring flowering shrubs at Scilly.** Although spring is certainly not the period of the year when the gardens of Tresco Abbey, in the Isles of Scilly, show their greatest beauty, the evidences of the equable climate are, perhaps, more apparent at that time, especially after the bitter winter experienced on the mainland, than later in the season. On April 15 *Edwardia macrophylla*, grown almost to tree size, was covered with its pendulous yellow flowers. *Cordyline indivisa*, not the *Cordyline indivisa* generally held to be identical with *Dracena indivisa*, but a species having sword-shaped leaves 4 inches broad, was flowering for the first time, the cluster hanging by the side of the stem after the manner of the bunch of a fruiting Banana, the individual flower-spikes, which are numerous and finger-shaped, being of a yellow and bluish-black colour. *Senecio Fosteri*, in large bushes 12 feet high, in profuse flower was a striking sight, while the fol-

lowing shrubs were also in bloom: *Boronia tetrandra*, *B. heterophylla*, *Pimelea decussata*, and several *Correas*, of which *C. cardinalis* had been blooming throughout the winter, *Banksia serratifolia*, *Eriostemum buxifolium*, *Anopteria glandulosa* and the Tasmanian Peppercorn, the scarlet Thistle (*Erythrolena conspiciua*) also showing many heads of brilliant flowers. *Berberis Darwini*, the white Broom and *Polygala*, as well as various *Rhododendrons* and Australian *Wattles* also brightened the gardens. *Fourcroya longava*, of which there are a large number at Tresco, had started throwing up its gigantic flower-spikes, one of the latter having in former years reached the height of 25 feet. On garden flowers in bloom I will not touch, except to say that a very beautiful effect was afforded by masses of *Lithospermum prostratum*, which, covered with their Gentian-blue flowers, informally outlined the verge of a border. *Muhlenbeckia complexa* flourishes like a weed in the gardens, garlanding trees with its graceful festoons and covering a hedge 10 feet high with its wiry stems and minute foliage. The Abbey gardens have suffered but little from the effects of the past winter (the greatest amount of frost registered being 5°), which has left a very different legacy to that of the disastrous winter of 1893-94, when several of the giant Tree Ferns were lost, as well as a splendid specimen of *Seaforthia elegans*.—S. W. F.

**Rhododendron (Azalea) rhombicum.**—This is the earliest of all the hardy deciduous Azaleas to come into flower, and is, moreover, one of the most distinct of that beautiful family. Although it is perfectly hardy and has come through the past winter quite unscathed, it is tender when young, a fact which probably explains its rarity in this country. The flowers are produced most abundantly over the bush before any of the leaves appear, the corolla being of a bright rosy-purple shade which is quite different from that of any other hardy Azalea. An example about 4 feet high in the Azalea ground at Kew is now very prettily in flower. The leaves, somewhat diamond-shaped and pointed at both ends, are covered with silky hairs when young. This species is a native of Japan, where, on the island of Nippon, it is said to inhabit the mountain forests. To those who are interested in early spring flowering shrubs it is well worthy of attention.—B.

**The Box as a specimen shrub.**—The assertion in a recent issue that the common Box is a much abused subject is, I think, quite justifiable. How seldom do we see it planted by itself where it can spread and develop to the fullest. Few, I think, have any idea to what proportions this shrub in good ground will attain. Some of the finest specimens I have ever seen are at Gunton, growing in the pleasure grounds. They stand quite clear of the neighbouring shrubs, and have plenty of air and light, and are most useful and handsome. The variegated forms appear to be more stiff and erect in growth, and not nearly so graceful as the common variety. Were I planting new pleasure grounds I would certainly accord the Box a prominent place amongst shrubs and give it plenty of room.—J. CRAWFORD.

**Protection of tender trees.**—Exposure to cold winds and draughts—in other words, want of consideration in planting—has more to answer for in the destruction of plant-life than even an exceptional amount of cold such as we have had during this last winter. In a garden in this village there is a specimen of *Eriobotrya japonica* now (April 30) looking the picture of health. It is 18 feet high, and the leaves are 16 to 17 inches long by 5 to 6 inches broad. It is in a thicket of shrubs, deciduous and evergreen, most of which are considerably taller, and is thus well protected. In the same garden is a plant of *Embothrium coccineum*, growing close to a small pond (in which *Aponogeton* is blooming freely); it is 8 feet high, and has a truss of flower buds on every branch. The open space in which it grows is nearly surrounded by trees and shrubs somewhat taller, and this amount of protection has enabled it to

bear at least 13° of frost with impunity.—W. T., *Bishopsteignton, South Devon.*

**Andromeda formosa.**—In common with many others, I could not find the specimen of *Andromeda formosa* to which an award of merit was given at the meeting of the Royal Horticultural Society on April 23, but at all events there seems to be a mistake made in thus recognising this decidedly ornamental shrub, for the genus *Andromeda* is closely allied to *Pieris* (indeed the names are often used indiscriminately), and last year at the meeting held on May 8 specimens of *Pieris formosa* were sent from Glasnevin, and an award of merit was then given. Surely this must have been overlooked, for merely a change in the generic name should not entitle a plant to be again recognised. This *Pieris* (for according to the "Dictionary of Gardening" *Pieris* is the correct generic name) is a native of Nepal and was introduced in 1881.—T.

## ORCHARD AND FRUIT GARDEN.

### THE FRUIT CROP.

It seems to be universally admitted that a grand crop of hardy fruit is this year inevitable, as never had we brighter prospects, a finer bloom, or more perfect weather to bring about its fertilisation. In but a week or two all will be over, as it is already with Plums and Cherries and many Pears, and on these, in spite of prevalent east winds, there is a fine set. A grand fruit crop may not prove to be to all an unmitigated blessing. That it will help to make the nation several millions of pounds richer there can be no doubt, but the distribution of that huge sum is not always properly arranged, for whilst some growers get a good share others get little or none—not because their products do not merit reward perhaps, but because local or other circumstances too often interpose to check profitable sales. Whilst between now and the autumn, when the bulk of the huge fruit crop will be gathered in, there may be some cause for battling with ordinary troubles, yet the ultimate outcome seems so far assured, that it is well even thus early to put the question, "How shall we most profitably utilise it?" It is very certain that should all go as anticipated, we must look for some two or three rather lean fruit years to follow, because that seems to be all in the course of Nature. That fact furnishes an additional reason, if one be needed, why we should thus early consider the best means of utilising this great fruit crop. A few who know how to market will do so satisfactorily. The many who do not know will find their fruit a drug and the market glutted. When such is the case, the moral derivable from a grand fruit crop is entirely discounted, because so much is heard of unprofitable sales, of great waste, and of consequent disappointment.

At the present time there is no question associated with home fruit culture so important as is the one, "How most profitably to market our produce?" We must, of course, entirely change our existing methods of getting fruit to market or into shops. Thus when the fruit harvesting comes we shall see the old rough, crude methods, the same crowding of certain markets, to the exclusion of others, the same imperfect packing and lack of sorting, the same evils repeated again and again, with the inevitable result that gluts are produced. We may expect the jam manufacturer to be strongly in evidence, and he will take for his purposes enormous quantities of fruit, but as he purchases at who esale rates, his prices do not admit of much profit. It is not in the direction

of jam manufacture by a long way that we must look for the highest uses to which good fruit can be put. It is in the home circle, used either as dessert food or as elements for sweets and sauces or as stewed dishes, that we must seek for that greater development of consumption which is so much needed. Why not gather the fruit with more care, assort it according to quality, pack into neat cheap non-returnable boxes, in quantities of 8 lbs., 10 lbs., 12 lbs., 15 lbs., or 20 lbs., to meet all requirements, the lids being easily secured and removed, whilst smartness and taste are presented in the packing, and thus open a wide connection with the grocers' shops and stores for several miles round? The assumption that only through certain markets and eventually greengrocers is it that legitimate fruit-trading can be done is a tradition that cannot be too soon destroyed. In many rural districts where small areas of fruit are numerous some collecting and distributing agencies could render most efficient service. No doubt we are, and in spite of all that has been written and said during the past twenty years, still growing far too much of inferior fruit, or our cultural methods are still such that only inferior samples result. It is too often the case that growers of market fruit depute the gathering of it to careless or untrained persons. In a private garden there is no work which commands the head gardener's personal attention more keenly than does fruit gathering. The untrained hand has no faculty for selecting the fittest, and in the process of gathering rarely does so with ordinary care. The subject here referred to is a most important one, meriting the fullest discussion, and such attention bestowed thus early in the year should have far more practical results than if deferred until the fruit harvest is here. A. D.

**Wasps.**—Judging by the immense quantities of queen wasps daily flying about, there will be no dearth of these enemies to fruit during the coming summer; and although we may kill all that we possibly can, more than enough will be left to work destruction. At the same time the deeds of the wasp are not altogether evil, as the queen wasps can be seen searching fruit and other trees in search of aphids, which they devour eagerly. *Psylla mali* also finds favour, as I watched them eating the newly-hatched psylla on several occasions recently; but the good deeds do not compensate for the havoc they work, and I destroy every wasp that I can, as aphides, psylla and other insects of that description can be easily got rid of by the aid of the reliable insecticides in the market, without depending upon such doubtful friends as wasps.—W. G. C.

**New Strawberries.**—I have recently had good opportunities of testing the quality of three new Strawberries ripened under glass. One of them (Royal Sovereign) is now very generally distributed, and many gardeners will have tried it this season in pots either for the first or second time. According to my experience this variety is a decided acquisition to the somewhat meagre list of forcing Strawberries. The plants under ordinary cultivation attain a great size, forming exceptionally fine crowns, and are just what a grower feels proud of. Very hard forcing is not advisable, but if included in the third or fourth batch of plants introduced into heat no mistake will have been made. In some gardens that I have visited highly creditable crops were ripe and ripening about the middle of April, the fruit I tasted being of excellent quality. Some that were sent me by post from a considerable distance travelled well, and such fine, bright-coloured fruit would early in May have fetched from 5s. to 6s. per pound in the best markets. Very large fruits are apt to become slightly hollow, but the handsomer, moderately large fruit do not show this failing, while the flesh in every case is firm and richly flavoured. Monarch,

another of Laxton's seedlings, will not, I fear, become popular as a forcing variety, as it does not set well in heat, but it will probably make its mark in the open and may succeed as a late crop in pots. It is of a distinct, sturdy habit of growth, the fruit large, handsome, and deliciously flavoured. Seeing that Latest of All is one of its parents, lateness may reasonably be anticipated. Laxton's Leader, however, can be forced, and this very fine Strawberry must eventually become popular. I saw it in Laxton's Bedford trial grounds last summer and was much impressed by its appearance and the rich, pleasing flavour of its fruit. Ripened under glass this excellence of flavour is even more evident, and very superior to what is often attained in the case of other varieties under pot culture.—W. IGULDEN.

#### BLACK HAMBURGH GRAPE.

THOUGH this is beyond question the most popular black Grape, it will be admitted by veteran growers that it is not so well grown now as it was

*Grape Black Hamburgh.*

formerly. Many will remember the grand examples that were exhibited at some of the leading shows about twenty years ago, but which are seldom, if ever, equalled now. It is not an easy matter to state why Black Hamburgh is less skilfully grown, as there is no doubt more than one cause for the degeneration. As mentioned in THE GARDEN a few weeks ago, I think the present system of feeding is unsuitable for the variety, as it cannot take up the copious supplies of food supplied to the roots; this is followed by a surfeit, and instead of doing service to the Vines, injury is inflicted, followed by small and frequently badly coloured berries, also smaller bunches than we used to see. On the old system of growing Black Hamburgh the border was well made with sound fibrous loam, with abundance of lime rubble and per-

fect drainage, and very often the borders were entirely outside, the Vines being brought through the wall into theinery. Afterwards very little manuring was done beyond a mulch of the best farmyard manure procurable every spring, and an occasional application of fresh lime lightly forked into the border. Considering how largely lime enters into the composition of the berries and the stones therein, it may be that some of the chemical manures now employed as a substitute for this do not answer so well as expected, more particularly on soils naturally deficient in lime. A manure that most Grape Vines enjoy is fresh guano. As a change from other stimulants it acts splendidly, and if anything is required to assist healthy Vines of Black Hamburgh, I can recommend the manure mentioned. For supplying a gentleman's table no black variety is more generally appreciated, as it possesses excellent quality, good appearance when well grown, and can be had in good condition from May to

December. With a little extra trouble good bunches may be kept until Christmas, but to obtain these, the Vines should be allowed to start naturally, and not be hurried too much by early closing during the summer months, and giving ample room for the development of the berries. Any jamming of the berries will be fatal to the bunches keeping, as decay would set in and the whole become tainted in a very short time. There is a host of so-called varieties of Hamburgh, including Frankenthal, but my experience is that there are only two really distinct varieties, and these are only distinct in the size and shape of the bunch. The better variety has fine broad shoulders, forming a bunch as wide as it is long, but still of good shape; the other has a more tapering bunch, with somewhat narrow shoulders, and under the best cultivation will never produce such a large and heavy bunch as the former.

W. G. C.

#### RUST ON GRAPES.

Most gardeners look upon rust on their Grapes as something to their discredit, and are always anxious to avoid this disfigurement if possible. There are many causes of rust on Grapes, but one of the most general, I believe, is injudicious ventilation, more especially up to the end of May. During this month we have hot days, but often a cold wind blowing that is felt by the tender foliage and berries of Vines, as proved by rust appearing on the latter, and frequently mildew on the former. So injurious is front ventilation to Vines in May, in my opinion, that I never have the front lights opened until the month is out, and experience has proved that the plan is sound. It may be asked, "How do you prevent the temperature becoming too high?" The answer is, by early top-ventilation. Immediately the thermometer rises to 70° a chink of air is admitted at the top, and gradually increased as the temperature rises, with an occasional damping down of the floors, walls, &c. By this means the thermometer never rises beyond a safe height. Where a mistake is made is in not commencing to ventilate early enough, then the air in the house becomes very heated early in the day, and if the sun continues

powerful all day it is very difficult to keep the heat within bounds without the aid of front ventilation and its evils.

Another cause of rust is the heavy removal of sub-laterals. Mr. Douglas mentioned this matter in a recent issue, and I agree with all he then stated on the bad effects of this severe mode of stopping Vines. In addition to the check given to healthy growth a sudden access of light is usually thrown upon the bunches, and the berries being accustomed to more shade are injured by the sun's rays, and rust or scalding follows, particularly with the tender-skinned varieties. Hundreds of bunches of Muscat of Alexandria are more or less rusted every year through a sudden or partial exposure to the light after being shaded by foliage. I think it an error on the grower's part to tie back or remove leaves at any time to admit direct light to bunches of Muscats, as some of the finest and most highly-finished examples that I ever saw had been shaded by a moderately thick canopy of foliage from the time the bunches were set until cut for exhibition.

Where red spider has been troublesome in the past, no doubt the pipes were sulphured with a view to ward off the enemy. It sometimes occurs that a portion of the sulphur remains on the pipes, particularly about the joints. I should not like to assert how long sulphur in such instances would throw off fumes, but there can be no question that it does not lose its power for a year or so, as it can be detected after that period when the pipes are hot, and probably many berries thus become rusted, as it is well known that the fumes of sulphur injure the tender skin of the berries while they are small. W. G. C.

**Grape Bowood Muscat.**—I am quite sure Mr. Temple will pardon me for correcting him in his error in attributing the notes on Bowood Muscat some time ago to the pen of Mr. Douglas. It was I who maintained that there was a distinction between the Bowood and Muscat of Alexandria, and I still do so. Its distinctive marks are shortness of bunch, rounder berries, and more freedom in setting. I do not mean to assert that it would be wise to provide for it at exhibitions now-a-days, as unscrupulous exhibitors might be induced to pass Muscat of Alexandria off as the true Bowood. This, however, has nothing to do with the actual distinction between the two Grapes. I am of opinion that if some of those who believe the difference to be more imaginary than real could see some of the old Vines that were planted when Bowood was first sent out, their opinion would soon be changed.—J. CRAWFORD.

## ORCHIDS.

### SOBRALIAS.

This genus contains many beautiful and distinct species, and appears to be becoming more popular every year. Sobralias succeed well in the temperature of the Mexican house, where I recently noticed some fine specimens in a small collection at Beckenham. These plants, especially *S. macrantha*, are in most excellent condition, and in some cases have a dozen and more fine flowering stems. One great disadvantage with this family of Orchids is the short time that the individual flowers last, but this is amply compensated for by the quick succession in which they appear, for no sooner does one flower fade than another opens, and the succession continues until the stem is quite exhausted. Sobralias are mostly all tall, free-growing plants with slender, reed-like stems, which are well fur-

nished with strongly-plaited deep green foliage, and make handsome specimens even when not in flower. They should be grown in pots of rather large size, as they produce roots freely, and the compost should consist of rough fibrous peat and turfy loam, mixed well together and made sandy. The drainage for this family, as is the case with all Orchids, must be well looked after, and about 3 inches of broken crocks should be given, for at no time in the year must the plants be allowed to be dry. An occasional application of weak liquid manure is also beneficial later in the season. Sobralias are all natives of tropical America, and when well flowered are unsurpassed in beauty by any other kind in the Orchid world. There are somewhere about thirty species, and the following are the most desirable kinds:—

*S. CATTLEYA*, which is represented in only one or two collections in the country, is indeed a remarkable plant. It is an exceedingly tall-growing plant, but I do not think it has ever been flowered under cultivation.

*S. MACRANTHA* is probably the most extensively grown kind in cultivation. It is a native of Mexico and Guatemala, and is an old inhabitant of our gardens. It will grow from 4 feet to 6 feet high, and even more, forming a fine specimen plant in a short time. The flowers of this species each measure about 6 inches across, with broad sepals and petals, the latter somewhat crisped. The whole flower is of a beautiful rich purplish crimson, having a pale yellowish blotch in the centre of the lip. Of this species there have appeared several varieties, a very fine form being known as

*S. MACRANTHA SLENDENS*, which, however, is identical with the type, but has the flowers of much larger size and very deep in colour. I have seen blooms of this kind nearly 8 inches across. Another and a very distinct variety is

*S. MACRANTHA* (Woolley's var.), which is of quite a different habit, not attaining more than 18 inches to 2 feet high. The flowers of this are probably the highest coloured of any. There are also many pale-flowered forms, and also an albino named

*S. MACRANTHA KIENASTIANA*, which grows as tall as the typical plant and is in every way identical, excepting in the colour of its blooms, which are of the purest white. This is a very rare plant, but is well represented in the celebrated collection of Baron Schröder and one or two other gardens.

*S. MACRANTHA PRINCESS MAY* is another distinct kind, of dwarf habit, growing from 2 feet to 3 feet high, and producing flowers with pure white sepals and petals, the lip beautifully shaded with delicate heliotrope. This is of recent introduction. During recent years also we have had some exceedingly fine species added to the genus. One of the most distinct is

*S. LEUCOANTHA*, imported from Costa Rica. It is of fine intermediate habit, and has flowers each measuring about 5 inches across. These are pure white, the lip being beautifully crisped and with a golden yellow throat, from which radiate streaks of orange. Another fine kind, and which makes a beautiful companion for this, is

*S. NANTHOLEUCA*, growing about the same height, and producing at the top of the reed-like stems enormous blooms of a rich yellow throughout. The lip is shaded with a deeper tint and beautifully frilled.

*S. HARDYANA* is another variety of exceptional merit, having fine broad sepals and petals of delicate blush, the latter being deeper than the former, whilst the lip is deep rose in front and golden yellow in the throat.

WM. HUGH GOWER.

*Chysis bractescens*.—A plant of this now in bloom in the collection of Mr. Moore, Chardwar, Brompton-on-the-Water, Gloucestershire, carries eleven fine blooms upon one spike. This, I think, is a very unusual number. It is certainly the

finest spike I have either seen or heard of, and it is undoubtedly a rare occurrence to find so many blooms upon a single raceme. This is a lovely, strong-growing, deciduous Orchid that enjoys plenty of light and heat. During the winter months a cooler temperature and very little water are necessary. It was introduced from Mexico about fifty-five years ago, and since that time it has often been sent home from other parts of South America with *C. aurea*, which latter it greatly resembles when not in flower.—W. H. G.

*Odontoglossum crispum*.—"Beginner" has just taken Orchids in hand, and has begun with some imported pieces of this useful kind. These should not be allowed to bloom the first season, that is to say, those which are already showing flower spikes, because the strain upon the plants before they become established will in all probability severely weaken, and possibly entirely kill them. It is a good plan to let the spike develop until the buds are produced, and then to pinch all these off excepting one or two, which will be enough to decide whether it is a good or bad variety. A few other suitable Orchids for amateurs other than *Odontoglossums* are *Cypripedium insigne*, *C. spectabile*, *Oncidium tigrinum*, *O. incurvum*, *Laha anceps*, *L. albida*, *Cattleya Trianae*, *C. Mossiae*, *C. Mendeli*, *Ada aurantiaca*, *Vanda Amesiana*, and *V. Kimballiana*.—G.

**Orchids at Sherwood, Beckenham.**—In the small collection in this garden are many fine varieties of useful Orchids now in flower, amongst them being good examples of *Cypripedium Lawrenceanum*, *C. barbatum*, both in good form, and a piece of *Schenburgkia tibicinis* carrying ten fine flowers. A beautiful variety of *Cattleya intermedia* is also open, as are *Lycaste cruenta*, *Oncidium incurvum*, *Brassia verucosa*, and a nice specimen of *Oncidium leucochilum*, a strong-growing plant, producing leaves each nearly a foot in length, whilst the scape, which is much branched, will often grow 5 feet or 6 feet high. The individual flowers measure 1½ inches in diameter, the sepals and petals are greenish yellow, barred with brown, and the lip when first open is quite white.—G.

*Oncidium Cebolleta*.—I recently noticed a fine plant of this curious species. It produces round, tapering leaves, each from 8 inches to 15 inches long, whilst the flower-spike seldom exceeds more than about half the length of the foliage. It has been found over a large portion of Brazil, Mexico and the West Indies, and consequently differs somewhat in the colour and markings of its flowers. These usually are yellow, spotted with chestnut-red, and in the best forms the lip is bright canary-yellow. In our gardens it is also known as *Oncidium juncifolium* and *Oncidium longifolium*.—W.

*Celogyne pandurata*.—This is a remarkable Orchid, the unusual colour of its flowers always making it a conspicuous object. A flower comes from "J. W." which measures quite 4 inches across, the sepals and petals nearly equal and of a uniform pale green, whilst the curiously formed lip is yellow, blotched and streaked with black. Although curious it is very pretty, and must be classed amongst the largest flowered in the genus. It was first discovered in the hottest jungles in Sarawak, and consequently requires strong heat and plenty of moisture under cultivation. This is not, however, the only green-flowered *Celogyne*, for there is another, also introduced by Messrs. Low and Co., of Clapton. This is *Celogyne Parishii*, the flowers of which are only about 2 inches in diameter, the colour yellowish green, the lip spotted and veined with black. In *C. Parishii* the flower-spike rises from the top of the pseudo-bulb, and in *C. pandurata* this proceeds from the side of the bulb.—H.

*Dendrobium suavisimum*.—This, among the brightest coloured of the golden yellow *Dendrobiums*, is an excellent Orchid for exhibition. It is strictly evergreen, having shortish fusiform pseudo-bulbs each bearing about three leaves, thick and leathery in texture. The racemes are produced from near the tops of the pseudo-bulbs and

the blossoms are deliciously scented. It is one of the freest flowering of this section, but unless the plants are vigorous it is better to restrict the number of spikes, as if too many are left the eyes at the base of the pseudo-bulbs are apt to become blind, the plants being apparently too weak to push new growths. When this occurs they must not be allowed to flower at all, or probably the plants will be killed outright, but every encouragement ought to be given to induce the eyes to break. If the plants have been long in the same compost they should be turned out of the pots and spread on a moist stage, treating them after the manner of newly-imported plants, replacing them in the pots as soon as they show signs of breaking. What causes this cessation of growth it is difficult to say, but overflowering certainly predisposes the plant to it. I have also noticed this in *D. chrysotoxum* and *D. clavatum*, but never in *D. densiflorum* or *thyrsoiflorum*, though possibly they are also subject to it. With strong and vigorous plants to commence with, there is no difficulty in keeping *D. suavissimum* healthy and obtaining a full complement of flowers annually. Like most of the evergreen kinds, it may be grown in the Cattleya house and should not be much dried at the root in winter, a few weeks' rest in a lower temperature being all that is necessary. Newly-imported plants may be established in very small pots, and at no time is a large receptacle necessary. *D. suavissimum* is a native of Burmah, and although sometimes classed as a variety of *D. chrysotoxum*, is abundantly distinct both in habit and flowers.—H.

#### ODONTOGLOSSUM CRISPUM VIRGINALE.

*ODONTOGLOSSUM CRISPUM* has been not inaptly described as the queen of Orchids, and the variety here figured is the most chaste and lovely form of the species in existence. Although many of the spotted varieties (*guttatum* section) possess greater value from a monetary point of view, this pure white variety must be awarded the first place for its delicate beauty, the glistening white of the sepals and petals and the refined appearance of the flowers having a subtle and indescribable charm possessed by no other kind. Although no other varietal name is recorded, *O. c. virginale* does vary both in size and in the width of the petals. A fine form that I flowered in 1893 measured 5 inches across the petals. These were each  $1\frac{1}{2}$  inches across, pure white, without any spot or marking except the yellow crest to the lip, and of great substance. *O. c. virginale* appears to have been named and first exhibited by Messrs. B. S. Williams and Son, of Holloway, at South Kensington in 1882, when it was deservedly awarded a first-class certificate by the Royal Horticultural Society. Since then it has appeared in many other collections, but good forms are still uncommon. Like all the varieties of this species, it requires a cool, moist atmosphere all the year round; the house where it is grown must be heavily shaded all through the summer months in order to keep the temperature as low as possible, and air must be admitted night and day. During the winter the plants must be arranged close to the glass, so as to catch every ray of light, and the temperature at this season ought not to fall below 48°. Very little is needed in the way of compost, a thin layer of peat and Sphagnum sufficing over the drainage, which must be sufficient to carry off the copious supplies of water that are needed during the growing season. If the atmosphere is right, the Sphagnum will grow freely and form a dense cushion around the base of the pseudo-bulbs, keeping them cool and causing them to root freely. A little of this may be removed on the approach of winter, but not suffi-

cient to bare the roots. Slugs and small snails work a good deal of mischief among the spikes when growing, and this entails watchfulness and care on the part of the cultivator. The culture of *Odontoglossums* was referred to somewhat in detail recently in *THE GARDEN*, and the treatment there advised for the typical *O. crispum* suits this variety in every respect. R.

#### SEASONABLE NOTES ON ORCHIDS.

THE almost tropical weather by day and the cold nights and harsh winds prevailing have lately necessitated a great deal of care and attention to the ventilation, shading and damping. In order to keep the atmosphere moist the syringe must be freely plied between the pots, and, excepting in the Cattleya house, fairly heavy syringings overhead are also advisable. These must not be given too frequently, however, or late in the day, as too much moisture about the young shoots at night is apt to cause decay. A little heat must still be kept in the pipes in the East India and Cattleya houses, this allowing of free ventilation in the mornings before the blinds are let down. All arrears of

*Odontoglossum crispum virginale.* Engraved for *THE GARDEN* from a photograph sent by Mr. W. Taylor, Glasgow.

spring potting should be seen to at once and the plants arranged for this season's growth. *Dendrobiums*, as they become established in the new pots, may have the lightest and sunniest positions, such as an unshaded end where they get the sun nearly all the morning, or where there is an opening between the blinds. *Thunias*, too, delight in a sunny position, and, like the aforementioned genus, like a brisk, moist heat. These and *Calanthes*, or other semi-terrestrial kinds potted some time since, are now growing freely and will require increased supplies of moisture as the roots run into the new compost. A deal of care is still necessary, however, and it is much better to err on the side of too little water than too much, as the old pseudo-bulbs are still fairly fresh and supply the young shoots with moisture sufficient for their sustenance. *Cymbidiums*, *Cypripediums*, *Aerides*, and other shade-loving Orchids will be better arranged in the body of the house, a little further from the glass where the action of the sun is not quite so powerful at closing time. It is not advisable to keep *Odontoglossum crispum* dry after this date, as any plants strong enough to flower should by this time have the spikes well advanced. A good soaking in a large pail or tub should be given every other

day until the pseudo-bulbs plump up, and care is necessary to avoid snapping off the flowers, as these are extremely brittle. As the earliest plants go out of bloom they may have the compost put in order, not disturbing the roots more than is absolutely necessary, and carefully watering for a time until the roots are again on the move. Large-growing *Vandas* of the tri-color, *suavis*, and *gigantea* type may be arranged on the central stage of the Cattleya house, where they will be subjected to a slightly lower temperature, but more sunlight than in the East India house, this consolidating the growth and being more conducive to free flowering. *Ceologyne cristata* is an accommodating plant as to temperature, but dislikes strong sunlight, and must on this account be placed in a shady corner. If not already done the plants must be looked over for insects and carefully sponged, or red spider and scale may possibly put in an appearance on the young foliage, greatly disfiguring it and weakening the plants. *Burlingtouia decora* is a straggling growing plant, and after flowering should have attention. The rhizomes may be notched half-way through between each pseudo-bulb, disposing these as regularly as possible over the surface of the compost, and filling in when necessary with fresh peat and Sphagnum. This is very advantageous to the plants, as many of the old pseudo-bulbs produce new growths, making a more shapely and better furnished specimen. In the cool house *Masdevallias* and *Restrepias* are flowering freely. These are very subject to the attacks of yellow thrips, and frequent fumigations have to be resorted to if the insects are plentiful.

*Disa grandiflora* is also subject to their attacks if not kept well syringed overhead and freely watered at the roots. The plants of this are best arranged close to a ventilator kept always open or near the door, as it is impossible now to keep them too cool under glass. Insects must be vigorously attacked on every possible occasion, and every care taken to promote a free, healthy growth in all departments. I recently saw a fine specimen of *Ceologyne asperata*, which is apparently not much grown. The racemes of flower are about a foot in length, but would probably be longer in very strong plants. Each flower was about  $3\frac{1}{2}$  inches across, the sepals and petals creamy white, the lip similar in ground colour, with a bright orange-yellow centre, from which radiate brown lines. The flowers are very agreeably scented, the pseudo-bulbs strong, and each bearing a pair of long lanceolate leaves over a foot in length. Being such a strong-growing kind it requires ample root room, and may be grown in equal parts of peat and Sphagnum, with plenty of small crocks. This species is a native of Borneo, where it grows on the banks and in the vicinity of rivers in low, marshy positions. It was discovered and introduced by Messrs. Hugh Low and Co. about fifty years ago, and thrives in a Cattleya house temperature. R.

#### SHORT NOTES.—ORCHIDS.

*Oncidium sarcodes*.—This is now commencing to open its blooms. It is of very easy culture, and

should be in every collection however small. The flowers are produced on long arching racemes, and individually measure upwards of 2 inches in diameter. The sepals and petals are clear yellow, heavily blotched with chestnut-brown, the lip bright yellow with a few small spots at the base. It grows on the Organ Mountains at considerable elevations.—G.

**Cypripedium macropterum.**—This is a cross between *C. Lowi* and *C. superbiens*, the leaves being prettily tessellated as in the latter. The flowers are large, with long, broad, drooping petals of a purplish-mauve colour, finely spotted with black. The lip is also of good form, helmet-shaped, and pale yellowish brown. It is a very desirable plant and one that is by no means common outside the best collections.—G.

**Schomburgkia tibicinis.**—I am in receipt of blooms of this from Geo. Challis, who states that they have been open and in full beauty for a very considerable time. Individually the flowers measure just on 3 inches across and are very showy. The petals are narrower than the sepals, more undulated, and of a rich purplish-rose; the lip is yellow, streaked with purple, the front lobe white, with a purplish margin. The flowers are produced several together at the top of a long spike, which attains several feet in length.—W.

**Burlingtonia fragrans.**—This sweetly-scented little plant deserves a place in every collection on account of the powerful fragrance of the flowers, which very much resembles that of our common Hawthorn. It is of dwarf habit and succeeds best upon a block of wood or in a shallow pan. It should be placed in a temperature similar to that of the *Cattleya* house. The flowers are pure white, with a stain of yellow on the lip. It is a native of Brazil, where it is said to grow on the highest branches of the Cedar trees.—W. G.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

MAY 14.

HAVING regard to the fast approaching Temple show of next week, the exhibits at the Drill Hall on the above date were most extensive. The Royal Botanic Society's show held on the following day would in a measure explain the presence of some few groups, which were taken from one centre to the other, but beyond all these possibilities the display was of a most encouraging character, no better testimony being needed of the increasing popularity of these bi-monthly meetings. The lecture created more than the usual amount of interest and was very well attended. Particulars relating to this part of the programme will be found in the detailed report following these remarks.

Hardy cut flowers occupied the greatest amount of space at this meeting, this being just the height of the season for late Tulips (Parrot and florist vars.) and many of the best species. The late Daffodils were staged in extensive numbers, so were other popular early spring flowers, as Spiræas, Pæonies, Violas, hardy *Cypripediums*, *Rhododendrons*, and *Lilacs* (in great variety, both single and double varieties). Cut Roses were also specially good. Of plants there was no lack to fill a goodly space; the best of these were a fine specimen of *Medinilla magnifica*, well-grown *Gloxinias* of a splendid strain, new *Caladiums*, as well as other choice varieties. Of Orchids there was not such an extensive display; nevertheless a number of very choice kinds was staged, *Cypripediums* in this instance coming to the front, several also of the Veitchian hybrids being strongly *en vogue*. The fruit committee was not in any sense heavily taxed, the most noteworthy exhibit being the new Strawberry Leader, to which a first-class certificate was awarded. Cucumbers are now coming forward in considerable numbers, but no new kind of marked advance was shown, although good types of varieties already in commerce were to be seen. The plan adopted of screening off a portion of the hall for the specially prepared specimens to illustrate the lecture was suggestive of what should be done to shut off the committees during their deliberations. It does

not seem to be altogether a difficult matter to do this instead of having the present arrangement of curtains, &c.

### Orchid Committee.

First-class certificates were on this occasion awarded to—

**CYPRIPEDIUM GODEFROYÆ LEUCOCHEILUM.**—A most beautiful and extraordinary form, bearing an enormous flower upon quite a small plant, the former being to all appearance quite out of all proportion to the latter. In outline the flower bears a resemblance to that of *C. bellatulum*; the dorsal sepal is, however, much larger, whilst the lip, instead of being spotted, is of a pure creamy white, this shade being the ground colour throughout, the other marking being dark bronzy purple spots running in lines in the dorsal sepal, whilst the petals were very profusely spotted in the same colour and fully  $1\frac{1}{2}$  inches in width. From Mr. R. J. Measures, Cambridge Lodge, Camberwell.

**CYPRIPEDIUM GERTRUDE HOLLINGTON** (*C. ciliolare* × *C. bellatulum*).—Previous hybrids have been exhibited resulting from this or nearly allied crosses, but the present variety surpasses them all and must be classed with the very finest hybrids now in cultivation. The growth is remarkably vigorous, the stout, fleshy, dark-coloured prominent leaves being some 3 inches across and 7 inches in length. The flower was also unusually large, with very broad semi-drooping petals fully  $1\frac{1}{2}$  inches wide; the ground colour of which and that of the dorsal sepal is a creamy white, with a profusion of dark vinous-purple spots and shading of the same tint on the petals, whilst in the dorsal sepal the same colour runs in veins. The lip is of extra size also and of a dark bronzy purple shade. From Messrs. H. Low and Co., Upper Clapton.

Awards of merit were given to—

**EPIDENDRUM O'BRIENIANUM ROSEUM.**—A dark rosy form of this beautiful hybrid between *E. radicans* and *E. evectum*, the spike of flowers being somewhat slender with the growth erect. *E. O'Brienianum* itself has deep crimson-coloured flowers, this form of it being quite distinct in this respect. From Messrs. J. Veitch and Sons, Royal Exotic Nursery, Chelsea.

**CATTELEYA MENDELI PRINCESS OF WALES.**—A most charming variety, the sepals and petals flushed with light pink, the most distinctive feature, however, being the intensely brilliant blotch of dark crimson-purple upon the lip, in contrast to which the old gold veinings in the throat stood out very conspicuously. From Mr. De Barri Crawshaw, Rosefield, Sevenoaks.

**ODONTOGLOSSUM CRISpum VAR. THE BRIDE.**—One of the most beautiful white varieties of this popular *Odontoglossum* yet exhibited, with flowers of the purest white, the sepals and petals of great breadth, the golden spotting upon the labellum adding to the beauty of each flower, of which there were fourteen upon the stout semi-erect spike. From Mr. W. Thompson, Walton Grange, Staffs.

**CATTELEYA MENDELI VAR. LEUCOGLOSSA.**—One of the most delicately beautiful forms of this fine *Cattleya* yet shown, the sepals and petals having the faintest possible flush upon a white ground, the labellum itself being pure white and deeply fringed, faint golden lines appearing in the throat, all traces of the crimson-purple being lost. From Mr. Thos. Statter, Stand Hall, Manchester.

Botanical certificates were awarded to *Dendrobium taurinum* (the Bull-headed *Dendrobium*), the sepals and petals yellowish green, the lip light purple, growth erect, the spike terminal with twelve flowers; from Messrs. J. Veitch and Sons; *Cirrhopetalum grandiflorum*, with larger flowers than usual, these being of a pale golden shade with dark veins (shown as *C. Macraei*), from Mrs. Langton, Reigate, and *Dendrobium Strongylanthum*, a botanical curiosity, and nothing more. From Messrs. H. Low and Co.

Messrs. J. Veitch & Sons sent a very bright and attractive group, comprising a variety of good

things, amongst which were *Laelio Cattleya Latona* and *L. C. Hippolyte* (*L. cinnabarina* × *C. Mossie*) with the traces of *L. cinnabarina* very distinct in both instances, the former with light orange-yellow flowers and those of the latter of the same colour, only deeper, a rose-purple suffusion being apparent. These are two superb hybrids. *Cattleya Mossie*, a fine dark form, *C. Mendeli*, *C. Schroederæ*, and *Laelia purpurata* in fine varieties were included, also several *Cypripediums*, as *C. caudatum* Wallisi with pale golden tail-like petals of great length, shaded bronze towards the extremities, the dorsal sepal being of the same colour and the inner portion of the lip of the purest white, the one spike bearing four flowers; *C. Euryale*, partaking greatly of *C. Lawrenceanum*, one of its parents, but with the petals spotted as in *C. Argus*; *C. selligerum majus*, a fine flower; *C. orphanum*, a distinct hybrid, and *C. Rothschildianum* in good form. *Chysis Chelsoni*, a lovely hybrid of rich colouring, deeper in this respect than usual; *Disa langleyensis*, a beautiful rosy pink hybrid with as many as twelve flowers and buds to the spike, the growth compact; *Masdevallia splendida* var. *Parlatoreana*, deep orange flushed with purple; and *Masdevallia grandiflora*, an extra fine form of *M. Veitchi*, which was itself also shown, were also sent. *Dendrobiums* were represented by *D. thyrsiflorum* with fine spikes, by *D. glomeratum*, a singularly beautiful *Dendrobium* with flowers of a rich rose-purple colour, the lip being singularly small and of a darker tint, and by *D. infundibulum*, a handsome species not now often seen. Of *Odontoglossums* there were good white forms of *O. crispum*, *O. triumphans*, and *O. Uro-Skinneri* in good character. *Oncidium superbiens*, a fine species of the *O. macranthum* habit; *Cymbidium Lowianum* with the crimson of the lip of a deeper shade than usual; *Oncidium ampliatum majus*, *Dendrobium Phalanopsis Schroederianum*, *Maxillaria Sanderiana* with extra fine flowers, the dark chocolate and pure white in decided contrast; *Odontoglossum Ruekerianum* with a good branching spike, and *Cypripedium bellatulum*, unusually vigorous in growth, were included (award silver Flora medal).

Mr. W. Thompson sent a smaller group consisting chiefly of extra fine forms of the best varieties of the *Odontoglossums*, amongst which were *O. cordatum aureum*, a pale golden form with its flowers singularly like those of a *Brassia* in style, and *O. Ruekerianum ocellatum*, an extra fine variety of deep colour, the flush of purplish rose and the deep chocolate spots making it very conspicuous, the flowers being of extra size also. *Odontoglossum Rossi rubescens* is quite a distinct form, the white having given place to pale rose in the lip and on the petals, the plant profusely flowered. *Odontoglossum Andersonianum* (Thompson's var.) has a clear white ground colour and chocolate spots and blotches, and others of a distinct crimson shade at the base. *O. crispum*, a singularly distinct variety, has some of the features of *O. Andersonianum* in its small spots, the whole flower being flushed with rosy purple. *Cattleya Skinneri alba*, which also came from Mr. Thompson, is quite a gem amongst *Cattleyas*, with the purest white flowers, every suspicion of colour as seen in *C. Skinneri* itself being obliterated, only the faintest trace of pale sulphur appearing in the throat (silver Banksian medal).

Other exhibits of Orchids were not numerous, still some few very good things were shown. Two very vigorous examples of *Phaius* sp. in the way of *P. Sanderianus*, but scarcely so handsome, came from Mr. H. Westman, Little Haywood. One plant bore two spikes and the other one; in each case these had already reached the height of  $5\frac{1}{2}$  feet, being scarcely more than half expanded (a cultural commendation was awarded). From Mr. H. Grinling, Harrow Weald, came *Cypripedium caudatum* Wallisi, not quite so far advanced as Messrs. Veitch's example, hence not so rich in colour. *C. tortile* came from the same source, its rather long petals being twisted; in other respects it bore some likeness to *C. levigatum*. Messrs. F. Horsman, Colechester, showed *Odontoglossum*

nat. hyb., intermediate between *O. maculatum* and *O. cordatum*. Mr. W. Cobb showed *Cattleya Mossiae* (Dulcote var.), in which the lip was broader than usual and deeply fringed. Mr. Smee sent from The Grange, Wallington, a noteworthy example of *Odontoglossum cirrhosum* flowering upon the old spikes of last year, as well as on this year's also. Mr. Cummings (gardener) stated "that the tallest spikes bloomed last year and afterwards produced bracts or leaves, flowering again on the same spikes this year. The other spike has been made this spring." Mr. Thos. Statter showed *Cattleya Clesiana* in the way of *C. intermedia*, having pale rosy-flushed sepals and petals and faint crimson spots, the lip being deeply fringed and much darker in colour. Mr. J. Gurney Fowler, Woodford, showed *Cattleya Mendeli* (Glebelands var.), a very fine form, with pure white sepals and petals (the latter being of extra breadth), the lip of a purplish crimson, with pale golden throat. Another variety of the same species had a rosy lilac lip and slightly flushed sepals and petals. Messrs. H. Low and Co. showed *Laelia purpurata* Schradlerae, having very faint purplish veins on the labellum; also *L. p. Russelliana*, in which a pale purple supplanted the deeper shade usually seen. *C. Schilleriana*—quite a gem amongst the dwarf species—was also included, bearing very fine flowers. A few hybrid *Cypripediums* in which *C. niveum* and *C. concolor* had made impressions were also included. From Mr. Ward, Salisbury, came a good form of *Odontoglossum crispum*, whilst a similar exhibit came from Mr. de Barri Crawshaw, who also had a twin-bulbed plant of *Odontoglossum Andersonianum* bearing a good spike.

#### Floral Committee.

Awards of merit were granted to the following—

**LILAC LA TOUR D'AUVERGNE.**—A handsome variety with a dense truss, the flowers mostly semi-double and of a deep rosy lilac colour. Shown by Messrs. Paul and Son, Cheshunt.

**SAMBUCUS RAEMOSA AUREA.**—A yellow form of the cut-leaved Elder, the colour of the leaves pale greenish-yellow, distinct and pretty, as the variegation is of a healthy tone. From Messrs. K. Wezlenburg and Son, Leyden, Holland.

**TULIPA ELEGANS ALBA.**—This charming variety of an old garden species has pure white flowers, with the faintest margin of red on the edges of the petals. The colour does not spread into the petals, as in another edged Tulip named *Picotee*. It is also useful for its late-flowering and has the tall, handsome character of the *Gesneriana* varieties. Shown by Messrs. Barr and Son.

**Tulips**—quite the chief feature of the meeting—were nobly represented in the great group of hardy flowers staged by Messrs. Barr and Son, which occupied one side of the Drill Hall. The late-flowering species included *T. Gesneriana*, *T. vitellina*, a charming cream-white Tulip; *T. flava*, *T. fulgens*, brilliant in colour; *T. elegans*, *T. Batalini* and *T. macrospeila*—all shown in quantity and fine form. It is a pity these Tulips are not more common in gardens. The new race of self-coloured *Gesner Tulips* was noteworthy in this group, and the varieties shown—about twenty in number—represented a selection of the very best, picked out from a trial of over 200 kinds. A fine lot of the florists' Tulip in breeder and rectified forms was also shown. We noticed that the visitors gathered round the noble *Gesner Tulips*, which in decided colours are by far the most pleasing. Irises in variety, single *Paeonies* in fine distinct kinds, alpine *Phloxes* and other interesting flowers of the season made up the group, to which a silver-gilt Banksian medal was awarded.

Mr. Ware, of Tottenham, also had a fine group of hardy flowers, comprising Tree *Paeonies* (pot plants), carrying numerous flowers, *Spiraea astilboidea*, *S. palmata*, and *S. japonica compacta*, *Sarracenia flava*, hardy *Cypripediums*, good specimens, carrying many flowers; *Anemone narcissiflora*, a pretty, little-known species; and cut flowers in quantity of the best late Tulips

in variety, Irises, and early flowering Gladioli. A silver Flora medal was awarded. A similar award was made to Messrs. J. Veitch and Sons, of Chelsea, for a large group of Tulips. The grotesque and showy Parrot varieties were most prominent, especially *Cramoisi* Brilliant, rich dark crimson; *Constantinople*, bright crimson; and *Perfecta*, crimson and yellow. A variety called *Coffee Colour*, of dull and dreary tints, seems hardly needed in this section. *T. Bouton d'Or* was good in this group, also *T. Gesneriana*, *T. fulgens*, and several bizarre and byblomen varieties. Messrs. Veitch also showed the following *Caladiums*: *Marquis of Camden*, large leaf, red, with darker coloured veins; *Sir Julian Goldsmid*, red veined, lighter red and white in the body of the leaf; *Lord Derby*, leaves soft rose, veined with green; and *Sir William Broadbent*, with bright red leaf veins, and blotched with white on a green ground. Messrs. J. Laing and Sons received a silver-gilt Banksian medal for a grand group of *Gloxinias* arranged with Ferns and Palms. The plants were carrying fine flowers of erect habit and rich colour, especially of note being *John Laing*, bright crimson self; *Mrs. J. Laing*, deep purple, with white margin to the petals, a large well-formed flower; *Majestic*, purple, with white throat; and *Lord Hillingdon*, crimson throat, and broad white margined petals. *Streptocarpus Royal Purple* in this group was conspicuous, having fine flowers, deep blue, veined with purple; also *Caladium Rose Laing*, the leaves of great size, white, with rosy tints about the centre of the leaf. Mr. G. Mount, of Canterbury, again showed *Roses* well, chiefly Hybrid *Perpetuals*, the best being *Mrs. J. Laing*, *General Jacqueminot*, and *Ulrich Brunner*. A silver-gilt Banksian medal was awarded. Messrs. J. Peel and Sons had a group of fine-foliaged plants, including *Caladiums*, *Diacaenas*, *Strobilanthes Dyerianus*, and *Begonia Arthur Malet*, the last two bright in leaf colour. A silver Banksian medal was awarded. Messrs. G. Paul and Son, Cheshunt, received a bronze Banksian medal for a group of *Cannas*, *Lilacs* in fine variety, *President Canot*, pale blue and double, *Marie Legraye*, white, and *Souvenir de Louis Spath*, specially noteworthy, and seedling *Rhododendrons*, hybrids between *R. Fortunei* and named varieties, one named *Mrs. C. Butler*, with large, soft flesh-pink flowers, being remarkably distinct and good. Messrs. J. Cheal and Sons, of Crawley, sent an interesting lot of cut specimens of the best flowering and coloured-leaved trees and shrubs, comprising the Japanese and other double *Cherries*, *Pyrus Malus* in variety, *Spiraeas*, *Rhodotypos kerrioides*, *Akebia quinata*, purple *Hazel*, *Acer platanoides* *Schwedleri*, with bright red leaves and other well-known trees. A bronze Banksian medal was awarded. Mr. Anthony Waterer showed *Lilac Souvenir de Louis Spath*, with fine deep-coloured, large trusses, and *Alba Grandiflora*, this latter named kind being also well shown from Panshanger Gardens. Mr. W. Paul, of Waltham Cross, sent some new *Roses*. *Clio* and *Corinna* are now well known; *Sylphe* has a pale pink flower, which deepens to rose, full and of fine form; *Empress of Russia* in its bold globular flower resembles *Archiduchesse Marie Immaculata*, but is distinct in colour, having that metallic and copper-red hue of *L'Idéal*. The flowers and growth indicate a robust habit. *Queen Mab*, a China variety, also promises well, with lovely buds of a deep buff colour, expanding into pale fawn yellow flowers. *Rose, Crimson Rambler* was shown by Mr. Hudson, of Gunnersbury House Gardens, in fine many-flowered clusters cut from a plant planted out in a greenhouse, and the same exhibitor sent a finely-bloomed branch of the *Judas Tree*. Mr. Moore, of the Botanic Gardens, Glasnevin, sent cut specimens of two *Brownias*, the flower-trusses of huge size, with the blooms crowded into a dense mass; *Crinum capense*, fine spikes from the open ground, and hybrid *Sarracenias*, one with pure white petals, others a dark brown red, and many in intermediate shades. A rich saffron-yellow *Globe Flower* named *Golden Gate* came from Messrs.

Koll and Sontag, Rhine Nurseries, Dusseldorf, and *Auriculars* and *Polyanthuses* were sent by Mr. R. Maitland, Comrie Castle, Dunfermline, Fife. A fine specimen of *Medinilla magnifica* bearing many of its large drooping flower clusters was shown by Mr. J. F. McLeod, Dover House Gardens, Roehampton.

*Daffodils* in competition for Mr. Barr's prizes were again shown, Mr. R. Maitland, Comrie Castle, being first, and Mr. C. J. Backhouse, St. John's, Walsingham, Darlington, second. Mr. Backhouse also staged another much larger group for the cup competition, but the three weeks' interval between the meetings has greatly handicapped the northern growers, and they were unable to show but few of the trumpet-flowered kinds. There was only one entry for the prizes for Tulips, Mr. J. T. Bennett-Poe receiving first prize for a well-grown varied lot.

#### Fruit Committee.

There was only a limited number of exhibits before this committee, specially interesting being Messrs. Laxton's new Strawberry and some Canary Island fruit and vegetables.

A first-class certificate was awarded to—

**STRAWBERRY LEADER.**—A very fine fruit, a cross between Noble and Latest of All. The fruits are wedge shaped, of a rich brisk flavour, and firm, the seeds being prominent. From Messrs. Laxton Brothers, Bedford.

From Syon House, Brentford, Mr. Wythes sent a very fine dish of *Amsden June Peach* to show its value for early forcing. Mr. Gilman, Ingestre Gardens, Stafford, sent a fair-sized Melon, a seedling white flesh and slightly netted, but too ripe. Mr. McLeod, Dover House, Roehampton, sent a nice dish of *Asparagus*. Mr. Mortimer, Swiss Nursery, Rowledge, Farnham, sent a dozen very pretty fruits of a new Cucumber named *Marvel*, the plant also being shown in fruit. Mr. J. Vert, Audley End Gardens, Saffron Walden, also sent some very fine Cucumbers, ribbed, and of great length, the varieties being *Vert's Improved* and *Vert's Favourite*. Messrs. Veitch and Sons, Royal Exotic Nursery, Chelsea, sent *Allan's Favourite Cucumber*. As there is to be a trial of Cucumbers at Chiswick shortly the committee requested that the above varieties be sent for trial. Messrs. Williams and Son, Upper Holloway, sent a new dwarf Bean growing in pots. This was shown at a previous meeting, and requested to be sent to Chiswick for trial. Messrs. Elder, Dempster and Co., Liverpool, sent a most interesting exhibit from the Canary Islands to illustrate Dr. Morris's lecture. This included a very fine bunch of Bananas, cases of Tomatoes and Fluke Potatoes, which were quite ripe and free of blemish. The Travelling Horticultural Co. sent models of their new houses on rails.

The lecture by Dr. Morris, of Kew, on the "Vegetation of the Canary Islands," received an added interest, being illustrated by the aid of the magic lantern, pictures of the vegetation of the islands being successfully shown on the screen. He briefly described the geographical features of the islands, remarking that every acre of soil cost £200 to obtain, as the natural soil lies buried beneath about 20 feet of large stones, which are gathered together and piled up to make roads and watercourses for irrigation, whilst not infrequently you might see them piled together in the middle of the field with the ground cultivated around. He briefly reviewed the vicissitudes the islands have passed through in connection with their commercial products, which began with the Vine, which was a success till the dreaded fungus *Oidium* ruined many plantations; later on the Sugar-cane was largely planted, but the staple and profitable industry of the present is the growth of Bananas, Tomatoes and Potatoes. As an instance of the richness of the vegetation in certain parts, he found 800 different plants in a small area, and of these, 400 are peculiar to the island, whilst only about 100 of them are at pre-

sent in cultivation in this country. Some plants sent from Kew—natives of the islands—were shown, including that fine Buttercup, *Ranunculus cortusifolius*, the well-known *Cytisus racemosus*, *Cytisus filipes*, a pretty kind with slender, green shoots and pure white, fragrant flowers. *Cineraria cruenta*, graceful and showy in the extreme, and others were shown; whilst illustrations of such as the Dragon Tree, Canary Palm, Fig trees, with large, but uneatable fruits, and Aloes, with towering flower-spikes, were shown. Space does not permit of giving more than the above bare outline of a lecture that was of special interest and much appreciated by all who listened to it.

### ROYAL BOTANIC.

#### SUMMER SHOW, MAY 15.

THE interest in this fixture certainly seems to be waning, and there was a distinct falling off in the competitive exhibits, whilst in many classes there were no entries at all. The miscellaneous contributions from nurserymen made up the greater portion of the display. In two classes for stove and greenhouse plants only one entry appeared, from Mr. Bond, gardener to Mr. S. T. Fisher, The Grove, Streatham. This group consisted chiefly of young Palms, Crotons, and Dracenas, such as would be used for table decoration, a second prize being awarded. Two classes for Orchids were represented by one small group, which was given first prize, from Mr. G. Cragg, Percy Lodge Gardens, Winchmore Hill. It consisted chiefly of *Cattleyas* and *Laelias*. Mr. Charles Turner was first for a group of Roses, showing good specimens, freely flowered, and delightfully fresh. The best H.P.'s were Juno, pink; Charles Lawson, deep rose; Ulrich Brunner, cerise; Camille Bernardin, and La France. Edith Gifford and Souvenir de S. A. Prince were good among Teas; also Celine Forestier and Crimson Rambler. Messrs. Paul and Son were second. Mr. Charles Turner was also first for specimen Azaleas, but the plants were mere dwarfs compared with the specimens we used to see. Marie Planchet, pure white, with petals undulated on their edges; Roi d'Hollande, deep red; and M. V. Savart, rich blood crimson, were noteworthy kinds. Mr. Scott, gardener to Miss Foster, The Holme, Regent's Park, was second. In the amateurs' class for specimen Azaleas Mr. Barrell, The Hoo, Sydenham Hill, was first with very formal rounded specimens. He was also first for a group of Azaleas, Mr. R. Scott being second. The first prize for Pelargoniums went to Mr. Charles Turner. Of show Pelargoniums, Mystery, Joe, Maid of Honour, and Comtesse de Choiseul were good. Among the fancies, Princess Teck, Fanny Gair, and Ellen Beck were the best. Mr. Ware, of Tottenham, was an easy first with a group of hardy plants, his best specimens being *Lilium Harrisii*, *L. davuricum*, *L. candidum*, *Iris germanica*, *I. florentina*, *Saxifraga pyramidalis*, *Phlox canadensis*, with *Spiraeas* and hardy *Cypripediums*. Messrs. Paul were second. Mr. Ware also received first prize for a very fine group of Begonias. The plants, dwarf and freely flowered, consisted of single and double kinds in equal proportions. The best *Gloxinias* came from Mr. Bond, and Mr. R. Scott was second.

A feature of the show was the grand group of Roses shown by Messrs. W. Paul and Son, of Waltham Cross, who received a silver medal. The specimen plants were finely flowered and comprised the best varieties. Mrs. John Laing, Clio, Denmark, Duke of Teck, Magna Charta, Caroline Testout, and Triomphe de Caen in Hybrid Perpetuals were noteworthy. Claire Jacquier, a climbing clustered *Polyantha* Rose with rich nanken-yellow buds and paler flowers, was shown in profuse bloom, whilst cut flowers in quantity of *Maréchal Niel*, Queen of Queens, Clio, and numerous other Teas and Hybrid Perpetuals made a conspicuous margin to the group. Equally meritorious was the group of fine-flowered and flowering plants set up by Messrs. J. Laing and

Sons, and with abundant room the arrangement was of an unusually high character, a silver medal being awarded. Many good Orchids were in this group, also *Nepenthes*, *Caladiums*, *Palms*, *Dracenas*, with *Gloxinias* and *Streptocarpi*. Messrs. B. S. Williams and Son had a large group of *Palms*, *Caladiums*, *Crotons* and *Dracenas*, a silver medal being awarded. Mr. R. Scott received a small silver medal for a group of flowering and fine-leaved plants, and a bronze medal was awarded to Mr. Perry, gardener to Mr. J. C. Tasker, Middleton Hall, Brentwood, for a smaller group of the same character. Roses, specimen plants, and cut flowers were also well shown by Mr. W. Rumsey, of Joyning's Nurseries, Waltham Cross, who received a silver medal, whilst a bronze medal went to Mr. G. Mount, of Canterbury, for a smaller, but meritorious, lot of cut Roses. Messrs. Veitch sent a group of Tulips which was given a silver medal, and Messrs. Barr received a small silver medal for Tulips and other hardy flowers, both exhibits practically identical with those that appeared at the Drill Hall on Tuesday. Mr. Ware received a bronze medal for a fine group of Tulips and early *Gladioli*, and a similar award for a group of Tree *Paeonies* grown in pots and carrying good flowers. Mr. T. Rivers, of Sawbridgeworth, showed fruiting plants in pots of Early Rivers Nectarine. The fruits were of large size and richly coloured. Trees of Early Beatrice Peach and May Duke Cherry in fruit were also shown. A silver medal was awarded. Messrs. Paul and Son were awarded a bronze medal for *Cannas* and *Lilacs* in fine variety. Cut flower decorations from Messrs. B. S. Williams and Son received a silver medal, the same going to Messrs. Dobbie for a fine display of *Violas*, *Blush Queen*, *Marie Stuart*, *Sylvia*, *William Niel*, *Iona*, *Gipsy Queen*, *Max Kolb* and *Picotee* being conspicuous. Standard plants of *Mignonette* were shown by Mr. W. Barrell. A *Carnation* named *Blenheim Beauty*, with large, white, purple-flaked, *Malmaison*-like flowers, came from Mr. T. Whillans, *Blenheim Gardens*, and Mr. Knowles, of Woking, showed *Daphne cneorum*, a variety rather darker in colour than the type, and said to be a fortnight later in coming into bloom.

A full prize list will be found in our advertisement columns.

### NOTES OF THE WEEK.

***Alstromeria pelegrina alba***.—This, one of the choicest of the species, is flowering capitably in a cool greenhouse at Shedfield Lodge. The pure white, delicately tinted green flowers are so pleasing, that it is a wonder this *Alstromeria* is not grown more largely.—E. M.

***Iris Cosnæ*** is a pretty Cushion Iris now flowering in Mr. Ware's nursery. It has a fine large flower, the standards clear yellow, with dark purple markings at their base, the falls of the same shade, pencilled with purple and with bright yellow crests. It is altogether a distinct and handsome flower.

***Lindelofia longifolia*** is a handsome spring-flowering, hardy plant of the Forget-me-not family, more robust than the old *L. spectabilis*. A bunch of it was noticeable in Mr. Barr's group at the Drill Hall on Tuesday. The flowers, of a deep rich *Gentian*-blue colour and nearly as large as those of the *Borage*, are freely produced on long leafy shoots.

***Iris nudicaulis*** is one of the best of the spring Irises, and, like *I. pumila*, makes charming groups and flowers with wonderful profusion. Mr. Ware has a quantity of it at Tottenham, and the plantations are a perfect sheet of rich purple flowers. These dwarf Irises ought to be popular plants, judging from their great beauty and easy growth in free, warm soils.

***Ixiolirion macranthum*** is a fine species well shown on Tuesday at the Drill Hall by Messrs. Barr. Its flowers, of a deep uniform blue colour, are large and long in the tube, and borne in fine

umbels on a long, stout stalk. *I. Pallasi* is another fine blue kind. The bulbs are best lifted every year, and planted again late in autumn rather deeply in light rich, well drained soil.

**Strawberry Scarlet Queen**.—Mr. A. Trail, The Gardens, Falsshaw Hall, Wilmslow, sends us some remarkably fine forced fruits of this Strawberry. The fruit is of medium size, bright scarlet in colour, the flavour brisk. Mr. Trail says he finds *Scarlet Queen* do well outdoors; the foliage has suffered less during the past winter than that of the other sorts which he grows.

***Anemone narcissiflora***.—This beautiful species is quite rare in gardens, and we were agreeably surprised to meet with it again flowering finely in Mr. Ware's nursery at Tottenham. It is a most distinct *Anemone*, producing its flowers in a truss at the top of an erect stalk 6 inches to 9 inches in length. The flowers individually are large, pure white, with a tuft of yellow anthers in the centre.

***Menyanthes trifoliata*** (the Bog Bean).—At the Tottenham nursery many aquatic plants are grown by adopting the simple expedient of burying half a cask, and the old Bog Bean is flowering well under this treatment. Although a native plant it is pretty enough to have in the garden, sending up its tall flower-spikes in advance of the leaves, the rose-tinted buds opening into pure white flowers.

**Strawberry Lesder**.—At the meeting of the Royal Horticultural Society on Tuesday another new Strawberry made its appearance, the second this season. The fruits in many cases turned the scale at 1½ ozs. This has a great deal of the old Pine flavour, so much wanting in many new varieties. This is the variety I noted last year as likely to make its way. It found many admirers on Tuesday and was thought to be a grand acquisition.—G. WYTHES.

***Cerssus pseudo-ceræus*** is one of the most noteworthy flowering trees of the present week. This species has a most distinct habit, quite different from that of the double forms of our native *Cherries*. It is practically an immense bush having no regular central stem, but long, rigid, ascending branches, bearing little side spurs now wreathed in flowers their full length. The flowers are semi-double and white suffused with rosy pink. This *Cherry* was figured in THE GARDEN of September 20, 1890.

***Atragene alpina***.—Among the climbing plants that flower in spring there are none more beautiful than this, and yet it is most uncommon. A graceful trailer and not over rampant in growth, it is suitable for low walls or fences about the garden. We have grown it on a low wall for years, and every spring it flowers with freedom. The past winter has not injured it in the least, and the flowers are now expanding in graceful wreaths and clusters of purple-blue. We saw a large batch of this *Atragene* at Mr. Ware's recently, and many of the plants less than 1 foot in height had several flowers, so that it blooms even in a young state. For a long time it was difficult to obtain this plant at all from English nurseries, but doubtless the coloured plate of it that was published in THE GARDEN of October 6, 1894, has drawn more attention to its beauty.

**Hardy *Cypripediums***.—Some well-grown, free-flowering specimens of these, in broad, shallow pans, that were shown in Mr. Ware's group at the Drill Hall attracted some notice. *C. Calceolus* (our English Lady's Slipper, but almost extinct as a wild plant) was in fine flower, its rich yellow lip conspicuous, owing to the peculiar brown shade of the sepals and petals, whilst it has a sweet scent. *C. pubescens*, also good, is an American kind, somewhat resembling the preceding and quite easy to grow in a damp, shaded spot with peaty or leafy soil. *C. occidentale* (or *montanum*, as it was labelled) is a Californian species of charming beauty. It has two or three flowers on a leafy stem, 1 foot in height. The sepals and petals are prettily twisted, of a brownish purple colour, whilst the neat-shaped pouch is white,

suffused with a faint pink shade and striped with pale red inside. It has proved quite hardy at Tottenham.

**Late Tulips for cutting.**—When at Syon House a few days since I saw in Mr. Wythes's house a handsome bowl filled mainly with the blooms of late Tulips. Associated with them were Lilac and one or two other flowers and some appropriate foliage, and the effect was delightful. The Tulips had been cut with long stems and when about three parts expanded, and they last fresh for a much longer time than is generally supposed. Gesner's rich crimson was among them, also several striking varieties of the Parrot group and the following, which deserve a place in every garden: Dame Elegante, white to pale sulphur, bordered with red, in the form of a feathering; Ida, or Bouton d'Or, clear deep golden yellow, a beautiful self of the finest form; and Picotee, white, with a fine beading of soft rose on the petal margins, as regular as in the case of a rose-edged Picotee. Three handsomer or more attractive garden varieties it would be difficult to name. Mr. Wythes plants masses of them on his hardy flower border, and also as a front line, where they are very effective.—R. D.

**Some good garden Tulips.**—Although we may question the wisdom of creating another name for what are really forms of the good old Gesner's Tulip, there can be no doubt as to their worth as garden flowers. The breeder Tulips in their self colours are lovely, but just as we have grown familiar with certain kinds we like, they break into odd bizarre mixtures of colour, and their garden value diminishes. The merit of these erroneously named Darwin Tulips is that they maintain their self colour for a more indefinite period, and thus for the future we can have tall late Tulips in the garden in many bright effective shades, all of the same stately character and bold beauty as the parent. Some fine kinds shown on Tuesday by Messrs. Barr are Gipsy Queen, dark maroon-purple; Purple King, also purple; The Sultan, darker than the preceding; Rouge Eclatante, bright red, with yellow base; Queen of Brillants, carmine-red with white base; Salmon King, soft light red; Scarlet Beauty, very bright; and Loveliness, all that the name suggests, clear bright rose in colour. If there is no self Tulip to surpass T. Gesneriana in its best form, we have at least in these varieties fit associates for it capable of giving much colour to the garden in May, and most welcome when the Daffodils are fading.

**Notes from Chester.**—After so severe a winter was there ever so lovely a spring? The profusion of spring bloom and the delicacy of the early foliage we never remember to have seen surpassed. The early-flowering trees and shrubs are very fine. We send you a box of blooms from representatives of but two botanical orders, which may fairly typify the glory of gold and silver and the prettiness of pink and white with the intermingling green about us in the spring garden. *Cytisus schipkensis* is one of the most delicate and striking of the legumes in flower just now. Its terminal flowers of pure white, surrounded with delicate foliage like an involucre, are admirable for cutting. It is perfectly hardy. *C. austriacus*, with its dense inflorescence gracefully arranged along the shapely flowering stems, and its compact foliage placed on short pedicels, is very telling, and either in bush form or as standards makes an effective show. *C. purpureus incarnatus* is a splendid contrast in colour. The purple flowers tinged with red are showy in broad masses, whilst the individual sprays are remarkably graceful and telling. The *Genistas* are all full of showy colour. We send two. *Genista pra-cox* is, as you will see, simply a golden shower. The effect of a mass of bloom standing out upon a lawn or within the shrubbery can hardly be described. *G. prostrata* has all the floral beauty of the Broom. The chief interest and value of *G. prostrata* lie in its remarkable prostrate habit, making it invaluable for certain situations for rockwork and the alpine garden. *Caragana pendula* is a never-failing

source of delight to the garden lover. Some of the standards here are simply laden with trails of gold and green, and there is no more conspicuous feature in the shrubbery edging the lawn. *Prunus sinensis alba plena*, with its snowy covering, is delicate and effective. As a pyramid or a standard it is equally desirable, and makes a pretty show. *Pyrus malus* in varying forms is lovely. The tinge of pink sets off the delicate beauty of the ground colour of the petals, and the slender and refined form of the buds and blossoms is charming. The Daffodils here have been remarkably fine from Easter onwards.—DICKSONS, Nurseries, Chester.

## PUBLIC GARDENS.

**Chrysanthemums in the Temple Gardens.**—It has been decided by the Temple authorities to discontinue for the future the annual exhibition of Chrysanthemums, which has now for a number of years formed a regular autumnal attraction in the Temple grounds facing the Thames Embankment.

**Opening of a new park at Willesden.**—On Saturday afternoon Roundwood Park, Willesden, was declared open to the public by Mr. Littler, Q.C., chairman of the Middlesex Sessions and of the Middlesex County Council. Mr. Pinkham, chairman of the district council committee, gave a brief outline of the preparations that have been made by the council. Twenty-six and a half acres of land, forming a conical hill overlooking Dollis Hill, Wembley Park and Tower, and all the public buildings of Willesden, were offered to the old local board for £15,000, but they declined to spend more than £14,000. One of the proprietors gave £500; the other £500 was raised by public subscription, and the ground was bought. Fourteen thousand five hundred trees and shrubs have been planted, and £9000 has been spent in laying it out, the drainage being especially difficult and costly.

## OBITUARY.

**Death of Mr. Thomas Hogg.**—By the death on Monday last at Berwick, at the age of 73, of Mr. Thomas Hogg, senior partner of the old-established Border seed firm of Hogg and Wood, Coldstream, the nursery trade of Scotland loses one of its most prominent figures. Along with Mr. Jas. Robertson, of Malahide, he founded and carried on the business so well known in Dublin under the style of Hogg and Robertson. He was also a director of Lawes Chemical Manure Company, Ltd.

**The late Mr. John Walker.**—To the brief obituary notice of Mr. J. Walker on p. 334 I venture to add the fact that at the age of fourteen years he came to Thame, and entered the service of his uncle, who was a grocer. While following this occupation his love for flowers led him to cultivate some of the pets of the florist in those days, and having made a reputation as a grower and an exhibitor, he in 1846, while remaining in the grocery trade, also established himself at Thame as a florist, commencing with about twenty poles of ground and a two-light frame. So successful was the venture, that in course of time it grew to thirty acres, a good quantity of glass, and two seed shops. The principal home nursery was known as the Lashlake Gardens, and here in a spacious lean to house he grew some of the finest and richest coloured Maréchal Niel Roses, which found their way into the London markets. Originally a Tulip grower and exhibitor in the days when the flower was somewhat extensively grown in the south, he still kept a collection, and a year ago brought to one of the meetings of the Royal Horticultural Society some very fine flowers, the flamed bizarries being particularly attractive. He put several new Peas into commerce, one of the most useful being that fine late variety Walker's Perpetual Bearer. It was he

who originated the Sugar-loaf Bath Cos Lettuce, the Exhibition Onion, &c., and he was famous for his very fine strain of quilled Asters, of which he raised several very fine varieties, and Sweet Williams. He was a most successful cultivator and exhibitor of Dahlias, and his white self John Walker is probably the best white Dahlia in cultivation. About forty five years ago he with others originated the Thame Horticultural Society, of which he remained one of the hon. secretaries till his death. The business will be carried on by his son, Mr. Stephen Walker.—R. DEAN.

**Royal Horticultural Society.**—We have been asked to state that the usual committees—fruit, floral and Orchid—will meet at the Temple Gardens at 11 o'clock on Tuesday, May 21, and that certificates and awards of merit will be given to new and rare plants if worthy. The official list of such awards will be issued from the secretary's tent on Wednesday, May 22.

**The weather in West Herts.**—Another unseasonably warm week and the fourth in succession. On six days this month the temperature in shade has risen above 70°, and on three of these above 74°; whereas the average maximum for May is only about 60°. The highest reading as yet recorded this year was 77° on the 13th. The preceding night was also warm, the exposed thermometer never falling lower than 49°. Rain is now much wanted in the garden, less than a tenth of an inch having fallen during the last nineteen days, while no measurable quantity of rain water has come through the 2½ feet of soil in either of the percolation gauges for eleven days. The atmosphere has again been very dry; indeed, the average difference at three o'clock in the afternoon between the reading of an ordinary thermometer and one with its bulb kept constantly wet was as much as 14° for the week ending the 12th inst. Since the beginning of the month the sun has shone brightly for ten or more hours on ten days, and on four of these for over thirteen hours. A Lilac came first into flower in my garden on the 8th, which is two days earlier than the average for the same tree in the previous nine years, but eighteen days later than last year. The only Rose which has yet flowered is *Rosa pyrenaica*, which was out on the 13th inst.—E. M., *Berkhamstead*.

**Book on British seaweeds.**—"Manual of the British Marine Algae," by Professor Harvey (Van Voorst). Many plant-like animals are commonly, but wrongly, called seaweeds; for which get Landsborough's "Popular History of British Zoophytes" (Reeves and Co). Much interesting information on both these subjects will be found in "Common Things of the Sea Coast," by Anne Pratt (Society for Promoting Christian Knowledge); "Glaucus, or the Wonders of the Shore," by Charles Kingsley (Macmillan); "Sea-side Walks of a Naturalist," by Houghton (Groombridge); "The Aquarium, or Unveiling of the Wonders of the Deep Sea," by Gosse; "The Sea-side Book," by Professor Harvey; "A Naturalist's Rambles on the Devonshire Coast," by Gosse; "A Handbook to the Marine Aquarium," by Gosse; "Tenby, a Sea-side Holiday," by Gosse (the last five works published by Van Voorst).—W. T. B., *Bishopstington*.

**Names of plants.**—*W. Butt*.—1, *Staphylea colchica*; 2, *Raphiolepis ovata*.—*Oakenhead and Co.*—1 and 2, impossible to name from such scraps; 3, looks like a Lupin; send when in flower.—*G. B. Anderson*.—*Epimedium pinnatum*.—*S. N. T.*—1, *Dicentra eximia*; 2, *Spiraea Thunbergii* fl.-pl.; 3, *Meconopsis cambrica*; 1, *Asperula odorata*; 5, *Ane-mone sylvestris*; 6, *Euphorbia lathyrus*.—*J. M. S. P.*—*Fritillaria pudica*.—*Geo. Goldsmith*.—1 and 3, *Fritillaria recurva*; 2 and 4, too far gone to determine.

**The Wild Garden: or, the Naturalisation and Natural Grouping of Hardy Exotic Plants, with a chapter on the Garden of British Wild Flowers.** Fourth edition, with wood engravings from drawings by Alfred Parsons, revised and enlarged. Tenby 8vo, linen cloth. Price 12s.; well bound in half morocco, 18s. Through all booksellers.

No. 1227. SATURDAY, May 25, 1895. Vol. XLVII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ORCHIDS

## CYPRIPEDIUM BELLATULUM.

ALTHOUGH a much better grower than some of the nearly-related kinds, this pretty species is not always satisfactory, and what is more remarkable is that in some places where apparently no particular trouble is taken in its cultivation it grows vigorously, while other experienced and assiduous cultivators do not make much of it. I have never been able to grow this species in peat and Sphagnum alone, but have been successful with it in a mixture of light fibrous, not sandy loam, chopped Sphagnum, charcoal, and finely broken crocks. Nodules of limestone I usually mix with the compost, but it is rather suggestive that the best plants I ever had were grown without it, so that perhaps there is not so much virtue in the limestone—other than as an aerating agent—as has been claimed for it. I would not advise anyone who had been successful with this material to discontinue its use, but I do not think it is by any means a panacea for all the ills that *C. bellatulum* and its allies are heir to. This Orchid is very susceptible to checks from fluctuations in the atmosphere, a constant and regular temperature being necessary to its well-being. A strong heat is also essential, and the plants must be screened from bright sunshine. The supply of moisture must be ample both at the roots and in the atmosphere, but no water must be given over the foliage, nor must it be allowed to collect about the base of the plants. This danger is obviated by elevating the plants a little, keeping the centre of the compost higher than the sides, and in the case of newly-imported plants this must always be practised.

*C. BELLATULUM* is a native of islands in the China Sea, and was introduced in 1888. On strong plants the leaves are from 8 inches to 10 inches in length, dark green, with a glossy-looking upper surface most beautifully tessellated, the reverse purplish red. The scapes are frequently twin-flowered, the blossoms being upwards of 3 inches across, usually white in ground colour, irregularly spotted with blackish purple. This flowers at various seasons, but usually during the spring and early summer. Another pretty species belonging to this section is

*C. CONCOLOR*, a smaller growing, but charming kind, requiring somewhat similar treatment. The blooms are produced on one or two-flowered scapes towards the end of the summer. The sepals and petals are concave, the lip small, the entire flower yellow with bright red spots. The leaves, each about 4 inches in length, are green and prettily variegated, the under surface purple. This was introduced in 1864 from Moulmein.

*C. GODEFROYÆ* is another pleasing kind, which grows about 6 inches high, the leaves being of varying shades of light and dark green on the upper surface, bronzy purple beneath. The flowers, borne on short stems, usually singly, sometimes in pairs, are white, with small dots of purple on the labellum and larger spots on the sepals and petals. It flowers in summer, and is a native of New Guinea and adjacent islands. Introduced in 1883. Another delightful species of this set is

*C. NIVEUM*, a dwarf-growing, free-flowering Orchid, a native of islands about the Malay Peninsula. The blossoms are pure white with

the exception of a few indistinct dots of red; the leaves are dull green, with a deep purple reverse. It flowers in May and June, and sometimes produces twin-flowered scapes.

All the above deserve a place in the most limited collections, as they are distinct and beautiful kinds. Some very fine hybrids have been raised from among them, and no doubt many more will be heard of as the seedlings come into bloom. R.

## CATTLEYA MENDELI.

This fine *Cattleya* belongs to the labiata group, and is a decided acquisition to that section, having flowers of large size and very brilliant in colour. These are produced during the months of April, May and June. In this group of *Cattleyas*, which also includes such species as *C. Trianae*, *C. Mossiae*, *C. Percivaliana*, *C. gigas*, &c., are to be found the finest in the genus, and there is no season in the year in which one at least of the different kinds is not to be seen in bloom. The species here referred to was introduced by Messrs. Hugh Low and Co., of Clapton, about fifteen years ago from the Cordillera of New Grenada, where it is often found growing in very exposed situations upon bare rocks. It was named in honour of the late Mr. Sam Mendel, of Manchester, at that time a very enthusiastic Orchid grower, and I believe it flowered for the first time in this country with Mr. Day, of Tottenham. *Cattleya Mendeli* has short clavate pseudo-bulbs, which each support a solitary deep green leaf. The flowers are produced on growths or bulbs that have been formed the preceding season, before the usual period of rest. In this respect it resembles *C. Trianae* and *C. Mossiae*. Such kinds as *C. gigas* and *C. Dowiana* flower from bulbs which have been formed during the current season. These blooms vary in colour, ranging from pure white to quite a deep shade, the rich purple and yellow of the lip being a very characteristic feature. The culture of this *Cattleya* is similar to that of all others belonging to the labiata group. It should be grown in a temperature of about 60° during the winter months, allowing it to fall about 5° less in the night, which as the season advances may be allowed to rise gradually until about 70° are reached in the summer. A thin shading will be found necessary during very hot sunny weather, but the plants should be placed so that they can receive as much light as possible. Care should be taken not to overpot these plants, and water should at all times be given with care. A good typical form of *Cattleya Mendeli* may be described as having flowers from 6 inches to 8 inches across, the sepals and petals white or delicately tinted with rose, the latter much broader than the former. The lip is very large, beautifully frilled at the margins, and of a rich purplish crimson, with a large yellow disc. Shortly after its first introduction it was also imported by Messrs. Backhouse and Sons, of York, and since by various other firms. Many fine and distinct varieties have appeared, these being distinguished by the colour of the flowers, and all decidedly worth a place in every collection.

*C. MENDELI BELLA*.—This is a very pretty kind, the sepals and petals pale lilac, the lip having a rosy mauve shade. It is a distinct and scarce variety, and was well represented in the collection of the late Mr. George Hardy, of Timperley.

*C. M. BLUNTI* is the albino of this species, and must be classed amongst the finest of all white Orchids. The flowers are of the purest white throughout, excepting a very small blotch of yellow on the disc of the lip. It still remains an ex-

ceedingly rare and valuable plant. It is named after the collector who discovered it several years ago, and sent it to Messrs. Low and Co.

*C. M. GRANDIFLORA*, as the name implies, is a very large-flowered variety, and at the same time has also very richly coloured blooms. The sepals and petals are white, very broad, and of fine substance; the lip large, deep rosy magenta, the yellow throat veined with rosy lines and the margin heavily frilled, where it is also margined with white.

*C. M. JAMESIANA* is another very distinct and richly coloured form, having the sepals and petals deeply shaded with rose, the latter distinctly blotched at the apex with a richer hue; the lip is bright amethyst-purple, the yellow portion very deep golden, veined with purplish lines. Another very beautiful variety is

*C. M. MORGANIE*, which is sometimes known under the name of *Cattleya Morganie*, but it is not distinct enough to bear a specific name, although as a variety it is one of the best. The flowers are of fine form and size, of the purest white, with a bright blotch of magenta near the apex of the lip, and a few radiating lines in the yellow throat. There appear occasionally some kinds which are decidedly worthy of varietal names, and amongst these must be mentioned two very distinct forms, which were recently shown at the Royal Horticultural exhibition in the Drill Hall. One is

*C. M. LEUCOGLOSSA*, a very distinct and elegant form, having delicately flushed sepals and petals, the large frilled lip pure white, veined with yellow in the throat. This is, no doubt, the nearest approach to *C. Blunty* above mentioned. This appeared in the collection of Mr. T. Statter, of Manchester. The other one shown at the same meeting was sent from the Rosefield collection at Sevenoaks and was named

*C. M. PRINCESS OF WALES*, a very charming and distinct form, the sepals and petals shaded with rosy pink, the well-formed lip having a very brilliant blotch of purplish crimson and golden yellow in the throat. Wm. HUGH GOWER.

## CLEANING ORCHIDS.

ALTHOUGH to the uninitiated the present may seem a peculiar time to be treating of cleaning Orchids, more experienced growers know full well the importance of giving the young growth a good start by ridding it of insect pests now, when these are coming from their winter quarters and instinctively finding the young growing shoots. In the East India house it is surprising how quickly the small white or brown scale spreads over the leaves of the distichous-leaved Orchids, and no better time can be found for clearing them than when they are young, their hold on the plants becoming more tenacious as the season advances. In consequence of this more force has to be used to remove them and the foliage is often bruised or punctured. At this time of year it is not advisable to use insecticides to any extent, frequent spongings with clear, tepid rain-water being quite as effective and less dangerous. When the insects are down between the axils of the leaves and the stem it is difficult to reach them with the sponge alone, and a small-pointed stick with a piece of chamois leather tied firmly to the top is often very useful, care being taken that the point of the stick does not protrude. A small black scale with a white lining often attacks *Cypripediums* of the *barbatum* and *venustum* types and is often seen in conjunction with red spider. Fumigations lessen their numbers considerably, and are always advisable if the insects are plentiful, carefully sponging afterwards. White scale on *Cattleyas* must now be looked for, as the young foliage, if once overrun with this insect, will always show the spots. It is frequently found clustering around the base of the pseudo-bulbs, about the rhizomes and dormant eyes, and should be rubbed off carefully with a pointed stick or stubby brush, the plants being afterwards forcibly syringed with tepid water. A soft, woolly insect of the *Cocco*s tribe—somewhat resembling mealy bug

but even more fecund—is very partial to cool house Orchids; and this, too, must be kept under, or the health of the plants will suffer. In examining the plants for insects a hasty look through the houses is not sufficient. Each plant must be taken and the undersides of the leaves carefully examined, for this is where the insects are chiefly found. In all cases where it may be found necessary to fumigate, this should be done lightly on two consecutive nights, as greatly preferable to one strong dose, and the syringe must be freely plied among the plants the next morning, air being given earlier than usual and the blinds let down before the sun reaches the house. This must not be undertaken unless necessary, green fly on the flower-spikes being usually got rid of by passing a damp sponge over them daily. H. R.

**Phalænopsis sumatrana.**—This very interesting species of the Moth Orchid usually produces its flowers during the months of May and June. It has always remained a rare plant, although introduced about 1864. The blooms, carried upon an arching spike—usually from six to nine upon a raceme—individually measure about 2 inches in diameter. These are not so showy as many in this beautiful genus, the sepals and petals being somewhat narrow, of a creamy white colour, whilst the lip is also of a creamy white, with a few purple lines on the front and a few orange spots on the side lobes.—W. H. G.

**Vanda parviflora.**—This very remarkable plant is generally known under cultivation as *Aerides Wightianum*. In growth it much resembles *V. Amesiana*, although the leaves are thicker and very fleshy. It is widely spread over a large portion of India and Ceylon, and has been imported on many occasions with other Indian and Burmese Orchids. It was introduced into our gardens about 1844, and was then named by Dr. Lindley as above. It has, however, various other names, such as the one just mentioned, which was also given it by the same authority as was *Aerides testaceum*, whilst Professor Reichenbach in 1877 named it *Vanda testacea*. The raceme is erect and many-flowered, the sepals and petals spreading, of a brownish yellow colour; the lip is three-lobed, the middle lobe large and spreading, white, stained and spotted with purplish mauve, and with raised lamellæ on the disc, the spur being of medium size. It requires strong heat to grow it under cultivation, as do most of the Orchids coming from this part of the globe, with plenty of moisture in the atmosphere.—W. H. G.

**Dendrobium thyrsoiflorum.**—Among recent importations of this species a great deal of variation exists in the flowers both in shape and colour. The typical form has the sepals and petals clouded white, the lip yellow of varying tints. From a small consignment of this Orchid received two years ago there are now several varieties in flower; one has very loose racemes, the blossoms being individually very large, the sepals and petals suffused with rose, the lip bright orange. Another pretty variety has the petals distinctly erimped on the edges, the colour being of the purest snow-white, and there are one or two others more or less distinct from the type. There are few more useful Orchids than *Dendrobiums*, and none more ornamental than *D. thyrsoiflorum* and the closely related *D. densiflorum*. Their culture is of the simplest description, and they thrive in an ordinary plant stove if care is taken to give them the proper resting and growing seasons. If there is not proper convenience for ripening the pseudo-bulbs, the plants may be taken out of doors when the growth is complete in August, and a month in the open air is of the greatest benefit to them, the slight check serving to make them flower more freely. During winter the temperature may be kept at from 45° to 50°, allowing just sufficient water to keep the pseudo-bulbs plump. The best season for repotting is directly the flowers are past, watering carefully until new roots are being emitted. The pots used should be large enough to accommodate the plants for three or four years, as they dislike frequent disturbance.—R.

## NOTES OF THE WEEK.

**Dracæna Godseffiana**, shown by Messrs. Sander at the Temple, and also certificated, is a striking kind, prettily variegated, but really more like a Bamboo, especially in its new growths, which are pointed, and enveloped in leaf sheaths like the canes of an *Arundinaria*. The leaves are oval, broad, about 2 inches in length, of a dark green colour, beautifully blotched and spotted with pale yellow.

**Incarvillea Delavayi.**—This new hardy plant from China was shown with fine flowers by Sir Trevor Lawrence at the Temple, and a first-class certificate was granted. It has long pinnate leaves and flowers borne on stout, erect stalks 9 inches high, there being from three to five flowers and buds on a stalk of the plants shown. The flower in shape resembles that of a *Martynia*, but the lobed petals are large and smooth, of a bright rose colour, the throat pale yellow.

**Clematis coccinea hybrids.**—Six fine distinct kinds of these were shown at the Temple by Messrs. Jackman and Son. This new race will be useful in gardening, as the varieties all have the hardiness and long-flowering character of the parent they most resemble, namely, *C. coccinea*. Duchess of York, which received an award of merit, has a lovely pale bluish flower, deeper tinted down the centre of the petals. Other good new kinds were Sir Trevor Lawrence, deep crimson; Duchess of Albany, lilac-rose; Grace Darling, deep rosy carmine, and Crimson Beauty.

**Calochorti.**—Even lovers of flowers know little of this quaint and charming family, but Dr. Wallace, of Colchester, is extending their popularity, and his exhibit at the Temple show, though small, as the season is yet early for these flowers, attracted many visitors. *C. Benthami* was much admired with its clear canary-yellow flowers covered with hairs inside, each petal having a dark purple blotch at its base. *C. lilacinus*, light purple, with large flowers; *C. coerules elegans*, pure white, the hairs of a purple tint; and *C. collinus*, having large flowers widely expanded, of a clear lilac shade, were all shown well.

**Good market Pelargoniums.**—The zonal Pelargoniums are largely grown by Messrs. Hawkins and Bennett, of Twickenham, who, like other growers of special flowers for market, rely upon few kinds, but grow these in enormous quantity. Of double red-flowered zonals the best for market work is *F. V. Raspail*, but a new kind not yet in the trade that Messrs. Hawkins and Bennett are growing will eventually prove a strong rival to the above-named kind. Its name is Duke of Fife, the colour bright crimson, the flowers individually very large in a bold truss borne on a long stout stalk, whilst its growth is all that can be desired. A free, neat-flowering, dwarf-growing double white variety that finds favour is Silver Queen. In single red-flowered varieties some of our old favourites still hold a high position, Henry Jacoby, West Brighton Gem, and John Gibbons being very popular, whilst Ferdinand de Lesseps, rich crimson, is found equally good. Lady Chesterfield was fine, with large trusses and flowers of a lovely salmon colour. In pink nothing is better than Constance, and there is a great demand for flowers of this variety this year. Niphetos is well named, as there is nothing in white single kinds to beat it for freedom and purity of colour.

**Notes from Baden-Baden.**—Some time ago *Fritillaria Thomsoniana* was nicely in flower. It has all the appearance of *F. macrophylla*, but does not seem to be identical with this; it is a much stronger plant, carrying on a thick stalk 3 feet high as many as 32 of its pink flowers. *Iris mesopotamica* is new; it resembles *I. sindjarensis*, but the flowers are pure white. *I. vaga*, which is different from *I. Leichtlini*, is very showy; it is very robust, 2 feet high, and the flowers have

shades of nut-brown, blue and rose. *I. bosniaca* with its pure yellow large flowers is one of the earliest and has much improved under cultivation. Just now *I. bracteata* and *macrosiphon* from the Pacific coast of United States are in great beauty, some strong plants carrying as many as twenty flowers open at once; they open of an ochraceous yellow colour with a maroon network and become white, the network changing to rose; they are very striking indeed. In quiet beauty with an aristocratic air stands *I. cashmeriana* with its large highly perfumed flowers. On the rockwork *Onosma albo-roseum* var. *macrocarpum* shows its large drooping bells from white to cherry-red and crimson. What a pretty flower *Habranthus andicola* is! Outside and half of inside not violet, but brilliant magenta-red, having inside a yellow ring and a black throat. It is a charming flower and the bulbs may prove even harder than those of *H. fulgens*.—MAX LEICHTLIN.

**Heuchera sanguinea.**—This is one of the best hardy introductions of recent years, the colour of the flower being distinct and rare in gardens, a pure red, without any suspicion of a taint either of blue or yellow. I think Mr. Smith, of Newry, was the first to add one of the inevitable nursery epithets to the plant—splendens, if I recollect right—and one of his plants which I had was certainly deeper in colour than the introduced type, but seedlings vary much in colour, and I have some which are nearly white; not that a white *H. sanguinea* would be desirable, but it shows how the colour may be varied by judicious selection. The plant in warm summers ripens seed freely, and occasionally I find them self-sown. The seedlings require patience, being slow of growth, but they want very little attention, and until they have flowered are decidedly harder than old plants. The species, being Californian, dislikes the cold damp alternating with frost of an English winter, especially in the stiff clay of Cheshire, and does best in a light, well-drained soil. Many gardeners complain that it is a shy flowerer, but where shelter from cold blasts and suitable soil are given it flowers very freely indeed in my garden, and never more freely than now. I must add that old plants in exposed situations are nearly destroyed, but masses of seedlings by their side are unharmed. In conclusion, this is a plant which requires frequent renewal, whether from seed or cuttings.—C. WOLLEY-DOD, *Edge Hall, Malpas*.

**Shrubs in Kent.**—I was glad to see some reports of the result of the winter in THE GARDEN last week. It would be interesting to have them if possible from all parts of the country. I presume we should find that the usually most favoured counties have suffered most severely. Here in the weald of Kent, about 300 feet above the sea, we have not very much to complain of, with the exception of the *Cistus*s, which are all dead. Though many things are injured, we have lost little. *Escallonia macrantha* and *E. philippiana* on walls are cut hard back and the former in the beds cut to the ground. *Abutilon vitifolium*, *Berberis Darwini*, *Pernettya*s and a shrubby *St. John's Wort* (which makes a shrub 4 feet high) are cut to the ground, but are shooting up from the bottom. The same may be said of the Gorse and Broom, both common and the varieties. Many deciduous shrubs—*Judas Tree*, *Leycesteria*, *Rhus Cotinus*, *Bladder Sennas*, &c.—have lost a foot or two all over, but are starting well. *Choisya ternata* on walls is not touched; in the beds it has lost its leaves, but is breaking all over. On the house, *Roses Lamarque*, *Fortune's Yellow* and *Waltham Climber* are cut down, but seem likely to recover. Some Laurels moved in the autumn are cut hard, but are breaking all over the stems. A few *Rhododendron ponticum* in a very exposed windy corner are a good deal browned, but as they seed and grow like weeds in the woods here, it does not much matter. Last, but not least, a *Chamaerops excelsa* which has had no protection for two years shows no sign of frost, and *Camellias* on the walls of the house are untouched; some small ones in the beds have lost their leaves. Altogether, think we may congratulate ourselves.—MEDWAY.

### OF SOME OLD GARDENS AND THEIR FLOWERS.

OUR chances of studying the best features of old gardens are very much lessened owing to the changes that took place a generation or two ago, when the taste for the newly-found effects of ribbon gardening led to many changes of plan and to the destruction of old parterres and flower gardens. But, so far as we know them now, it may be safely said that their charms are in nearly all cases greatest where they are disposed more with regard to the ground itself and the house than where the ground has to conform to any fixed idea as to style. We see evidence of this at

world, the walls afford such admirable backgrounds for flowers of the right sort. There is no house takes a better colour than the old English house; none so precious for a background. How very different the stucco or hard brick or other house new or old; with these the common style of carpet gardening may not seem so incongruous. It is when we come to see it displayed before a beautiful old house that its hollow pretensions are almost painfully evident. For of what value are silver-lichened walls 300 years old or more to us if there be but a few lines or masses of Lobelia and such trivialities in front of them? From such things, no matter how disposed, we get what artists term "hardness" and showy

only artistic ones; the way may vary much according to soil or climate, but beautiful results near a house can only be got through more enduring planting than is now the rule. It should not require much to prove that in every way a bed or group of such a Rose as Bouquet d'Or, with its free and handsome shoots, would be far more delightful near an old house than any plant of summer growth only, and yet we see it stated now and then that once a parterre (of the ordinary sort), always a parterre, and that we must not venture on any free and lasting planting near the house.

It is, however, one of the most puerile of errors; there is no good reason why we should not return to as lasting ways of planting as ever the old gardeners employed. On the contrary, there are reasons why we should do much more of it, because we have a greater choice of beautiful evergreens and long-lived plants of various sorts which have also the precious qualities of beautiful bloom, as in, say, the case of the climbing Tea Rose, the choicest hardy Rhododendrons, and such evergreens as *Andromeda japonica* and *Kalmia latifolia*. Large flower gardens of all kinds would be greatly the better of being broken up with groups or masses of such things, which among their other merits would enhance the value of the flower masses.

And going to larger things still, why should they be excluded from the flower garden where there is room for them? I remember at Knole years ago seeing a beau-

*Haddon Hall. Engraved for THE GARDEN from a photograph sent by the late Mr. J. L. Robinson, C.E.*

Powis, Ightham, Naworth, Berkeley, Cotehele, Knole, Penshurst, and other places. Every old garden is not excellent in plan, as the most simple means of improvement are often neglected in such places, but generally they illustrate the point insisted on, that the happiest results are got where the ground itself is thought of first and most. This is nowhere more clear than in a few places where a very modern garden has been made near an old house, but where some of the old gardens remain. For instance, the modern flower garden at Drayton is distinctly less charming than the older parts of that beautiful garden.

About these fine old houses the opportunities for flower gardening are the best in the

colours. But showy colour is not always good colour either in pictures or in gardens, and some of the most beautiful pictures both in gardens and otherwise are where the brilliance is in due relation to other things of equal importance. Some of the most vivid pictures of the master landscape painters are got by a modest amount of high colour in its right place, and so it should be in gardens.

But it is not the colour only we have to think of in these old gardens, as we miss beautiful and varied forms of stems and mass of foliage when we use only the short-lived summer flowers.

For all such houses and for all beautiful houses permanent ways of planting the beds are the best, and indeed the

beautiful group of the Swamp Magnolia (*M. glauca*) in flower the like of which I have never seen since. There is too much neglect of beautiful flowering shrubs, and one cause of this is their needless exclusion from the flower gardens of the day.

If this be true of the beds and borders of the garden, it is even more so of the walls. About old houses they are more than ever precious from their colour and material, and from a flower garden point of view it is folly to neglect them, and no care is too much to give to select the noblest plants for them, in due relation, of course, to climate and soil. Unfortunately, it has been too much the rule with architects who make gardens to forbid the planting of the walls—the surest way to

make a garden "hard" and without real beauty. It was not the case in really old English gardens of which the walls were well set with climbers. Now we have a much larger choice of beautiful wall plants, many of them in our climate distinctly better for the warmth and shelter of the wall, as is the evergreen Magnolia on many an old house. Were it not for the trees of this planted on the walls of old houses and old gardens, we should not in our country ever see in flower the noblest of evergreen flowering trees. The double Pomegranate is another example of a brilliant flowering shrub which may be bloomed well against warm walls, but which is far too rarely planted thereon. The variety of aspect round our large old houses like Drayton helps also towards getting the best effects on such walls, which indeed about some old houses are a garden in themselves. Indeed, some of our pleasantest souvenirs of gardens are of wall plants as at Ollington, where so many rare shrubs are on the walls, and in the College Botanic Gardens at Dublin, where there are such picturesque effects from the growth of a great variety of plants which cover the walls admirably, and at the same time are never stiff, but garland them with charming grace.

W. R.

## FLOWER GARDEN.

### NARCISSUS CULTURE IN THE ISLES OF SCILLY.

As on a fine April evening one steams to the south-westward from Land's End, and descends on the horizon the little group of islands that lie in the sunset, it is hard to persuade oneself that it is from them that London and most of the provincial towns of England draw their chief supplies of Narcissi during the winter. When, however, the *Lynesse* makes fast to the wharf at Hugh Town, St. Mary's, and the piles of white wooden flower-boxes are seen lying there, tier upon tier, an idea of the magnitude of the traffic forces itself upon the traveller, and if he should stay to see the steamer discharged, he will find that nine-tenths of the cargo consists of empty boxes returned by flower-salesmen from all parts of England. The industry, in which almost every occupier of ground in the Scillies is now concerned, is the chief, one might almost say the sole, trade of the islanders. Conceived by Mr. Dorrien Smith, the proprietor of the islands, and fostered by his judicious care, it is now so firmly established that nothing short of a reversal of the taste for cut flowers during the dark days of the year on the part of the town dwellers of the mainland is likely to affect the prosperity of the Scillonians, for with the mild and equable climate which the islands enjoy, competition is practically out of the question.

The one enemy that has to be contended against is the wind, and to counteract its baleful influence, lines of shelter in the form of hedges, walls, palings and reed fences are to be seen at distances of a few yards in the Narcissus fields. In St. Mary's the hedges are almost entirely composed of *Euonymus*, this standing the winter well and providing a good protection. On Treseo, on the other hand, *Escallonia macrantha* takes the place of *Euonymus* as a shelter plant, and covered, as it is in

the late spring, with pink flowers, the guardian hedges are themselves objects of beauty.

A walk round the island of St. Mary's in the early morning soon illustrates the hold that flower culture has upon the island. Carts are driving to and from the quay, coming in with full boxes and going out with the returned empties. Here, one comes upon three boys and a man picking *N. poeticus ornatus* in a small enclosure. Already several large heaps of the white blooms lie at the foot of the hedge, and, while we wait, a young woman crosses the road, fills a basket with flowers, and takes it to a lean-to glasshouse that adjoins an unpretentious granite built cottage. Following her, we find that the greenhouse shelves are already more than half filled with thousands of cut Narcissi in water. Continuing our walk, we see in small fields lines of dark red Wallflower, which men are busily gathering, bunching and placing in hampers. A light-coloured patch in the next enclosure turns out to be a colony of white Stocks, and further on in a cottage garden, a wide bed of Arums appears between masses of Grand Monarque and *poeticus ornatus*, which are now in full beauty; but Wallflowers, Stocks, and Arums together do not occupy one-twentieth part of the ground that is devoted to the growth of Narcissi, and their culture may be regarded as merely a tentative experiment. On every side the waving blue-green leaves are to be seen, bed after bed and field after field, of Narcissi. Even beneath the very ramparts of the disused battery they grow, sheltered by rude palings of barrel staves from the wind and the sea which they overhang. Though the island is not covered with glass to the same extent as Guernsey, many glasshouses have been erected during the last few years, which serve the double purpose of forcing the bulbs for early flower and providing well-lighted packing sheds. It is, however, not until the island of Treseo is visited that the industry can be studied in its highest development. Here, at Mr. Dorrien Smith's flower farm, no outlay that may lead to the commercial advancement of the trade is spared. No innovation is too unimportant to be tried and, if approved of, adopted.

Close to the bulb fields are two blocks of ridge-and-furrow glasshouses, each block containing five houses, the total run of the ten houses amounting to 15,000 feet. These are heated by horizontal tubular boilers, and in them during the winter thousands of boxes of Narcissi are forced on temporary staging erected over the hot-water pipes. As the boxes are taken out in the spring they are placed in the open and the bulbs ripened off, when they are planted again and are ready for another forcing in two years' time. As soon as the bulbs are cleared out, the staging is taken down and the houses are filled with Tomatoes, which are grown exclusively in pots and which, on April 16, were just commencing to colour. By the time these have to be removed to make way for the staging on the approach of winter a good crop has been obtained, about 15 tons having been cut during 1894. Close to the glasshouses stands a large packing shed about 200 feet in length. In the interior, along the front, the upper portion of which is glazed, runs a wooden trellis supported on a shallow water tank, and through the interstices of the trellis-work the stems of the cut Narcissi are inserted, thus enabling them to absorb sufficient moisture to bear a long journey without flagging. Up the centre of the shed a closed-in tank extends, about 2 feet 6 inches high, with movable boarded top in sections, containing about a foot of water heated by pipes. In this baskets of

the earliest forced flowers are stood before fully open, a slight syringing is given, the tank closed, and when the top is removed the blooms are expanded and ready for packing. From the centre of the roof, or rather ceiling, immediately above the tank alluded to, hangs a wide shelf on which are placed 6-inch holeless pots filled with water, and which are utilised for holding the heavy trumpet section of Narcissi, it having been found that treated thus they are exempt from injury to the trumpets which occasionally occurs when they are inserted in the wooden trellis.

On one day during the week preceding Easter this house contained 300,000 flowers, which were bunched and packed in six hours by the experienced staff, whose dexterity in handling the blooms is the result of intelligent supervision and constant practice. In the same week over 50 tons' weight of boxes of flowers was dispatched from the Isles of Scilly to the mainland.

The pickers carry with them india-rubber rings. When as large a bunch as they can conveniently handle has been gathered, a ring is slipped round the stems and the bunch is laid down. These bunches are then collected, deposited in hampers, stem downwards, and driven to the packing-shed, where the bands are removed and the flowers placed in water. Before packing they are tied in bunches of twelve, all the flowers facing one way. The boxes, which are made on the estate, are fastened down with string alone, and not more than three boxes made into one package.

The soil of Treseo seems admirably adapted to the growth of Narcissi, the foliage of the larger varieties, such as Emperor, Empress, and Sir Watkin being extremely strong and healthy. I found that some single bulbs of Emperor which I examined had produced five flower-stems. In view of the fact that the islands will soon become exporters of bulbs in quantity, as well as flowers, it might be well for English growers to consider the advisability of procuring supplies from this source instead of relying on the imported Continental-grown bulbs. At the time of my visit a bulb of Empress that had been accidentally dropped at the foot of a hedge, and which merely lay on the soil, had rooted strongly and was carrying two fine flowers, while some scales of *poeticus ornatus* that had found their way into a heap of refuse soil had developed into a fine clump.

Of the Polyanthus section, *Gloriosus* seems to be the most amenable to forcing and pays well when this system is resorted to, but, gathered from the open, is inferior in value to Grand Monarque and Soleil d'Or. *Obvallaris* is a useful variety, and being the earliest Narcissus proper and of a bright colour, brings in a good price when forced. The season commences with the Paper-white, which, however, is not in particularly great request at the Scillies, as even when unforced it comes in during December, sometimes even in November, and up to Christmas the Chrysanthemum has the call in the market. The last Narcissus to flower is *poeticus plenus*, which is marketed in May.

Emperor, Empress, Sir Watkin and Golden Spur are among the varieties that are grown in quantity, while *Barri conspicuus* is a coming flower and bids fair to become popular, but it is doubtful if it will ever become such a favourite with the flower-loving public as the white-petalled varieties of *poeticus*. In the experimental garden by the old abbey a fine collection of the rarer varieties is grown, amongst which Duchess of Westminster, Catherine Spurrell, Glory of Leyden, Madame de Graaf, Tortuosus, Cernuus, Burbidgei, Robin Hood, Duchess of Brabant, Macleayi, Santa Maria and Queen of

Spain were especially worthy of notice. In the rock garden, *Narcissus Bulbocodium sulphureus* and *N. triandrus albus* were flowering well.

I am unable to give any reliable data as to the average prices realised by the different varieties during the season, but the week after Easter I was shown at St. Mary's a memorandum that had just been received from a provincial salesman, in which the prices fetched by the last consignment were given. They ranged from 1s. to 4s. per dozen (bunches of twelve blooms), the highest value being obtained for Sulphur Phoenix. This is, of course, no criterion of the prices realised during the winter, when I was informed that the returns sometimes reach 18s. to 20s. per dozen.

S. W. F.

## NOTES ON HARDY PLANTS.

**Primula arototis.**—Of all the species and natural hybrids I know, this most nearly approaches blue. It is a reddish purple, though why we should be so anxious for the colour blue in Primroses I do not know, for in their flowering season we have masses of this colour in other genera. It should be stated, however, that this is a variable *Primula*, even more, perhaps, in the form of its foliage than the tint of its flowers. I have several specimens just now with big leaves not only irregularly toothed, but deeply lacerated and almost approaching the pinnate. I know no other *Primula* of the Auricula section so widely removed from the entire leaf form. As the plants grow older they become more characteristic.

**Arctostaphylos californica.**—This is a strong grower compared with the better known *Uva-ursi* and alpina, larger in all its parts and of a more sprawling habit. It is to be recommended as an evergreen creeper for half-shady banks or rock gardens, but its chief point is the free manner in which it flowers, and the pretty pink blossoms are arranged in compact clusters. I set my plant in an off-handed way on the north side of the rock garden in good loam and leaf-mould, placing on its long stems good-sized stones, and the result is that under the stones there is plenty of new roots, and it promises to soon cover its allotted space.

**Dianthus microlepis.**—Of all the *Dianthi* I have ever grown this is by far the earliest to bloom. It opened its first flowers on the last day of April in this late season. To have any Pink thus early must be a desirable feature, but this is not all that can be said in favour of this plant. The habit is tufted and very dwarf, not more than 3 inches high, including the bloom, which stands well out of the grass. True, the flowers are small, but they are very sweet and of an attractive rosy carmine hue.

**Calceolaria plantaginea.**—I have noticed that though this flowers more satisfactorily in low or damp positions, such positions have not always enabled one to find such healthy growths in spring as are found in warmer or drier soil, where it never fails to live and spread.

**The Wood Anemone (nemorosa).**—A blue form of this which I have been growing for six or eight years, and sent me from a Welsh wood, has been exceedingly fine this spring. The flowers are each 2½ inches across, and with more of the blue tint in them than I get in my plants of *Robinsoniana*. It was not so at first; for two years they were not to be distinguished at all from the common form, but year by year they have got larger and more blue. In the same way off-sets that have been moved have gone back to the normal form, but change with years when left alone.

**Ranunculus bilobus** is a gem of the first water. In early April the fresh reniform leaves were quickly succeeded by flowers of snowy whiteness and as large as a florin, and though the plants were but 3 inches high, the flowers were very conspicuous.

**Primula variabilis**, so far as I have ever proved, has deep ruby red flowers, otherwise it is not distinct, belonging to the Auricula. There is a tendency, I believe, in certain quarters to give special names to but the merest or slightly varied forms, and this almost seems to be such a case. Anyhow, it is certain that this plant is not the *variabilis* of Goupil, which belongs to the Cowslip section.

Woodville, Kirkstall.

J. WOOD.

## THALICTRUMS.

(MEADOW RUE.)

THE species and varieties which constitute the above genus include several which are well suited either for the border or the rock garden, while a few of the more robust would be useful

in the wild garden. But with these plants, as with many others, the most has not been made in a large number of instances. Isolated examples of some of them may, and indeed are, frequently seen in those gardens devoted to hardy plants, and very pleasing and effective they are when seen in good condition. When in flower their feathery plume-like heads form one of the most distinctive features in the garden. This is particularly true of the forms of *T. aquilegifolium*, which have probably the largest flowers. Few plants are more easily cultivated, and the majority succeed well in light loamy soil. In those gardens where heavy or very cold soils exist, the addition of some sharp

grit and decayed leaf soil will assist in keeping the soil open. The more robust-growing kinds, such as *flavum*, *lucidum*, *rugosum*, and *glauceum*, are more at home in a good loamy soil. If this be fairly rich and deep, these kinds will annually attain to from 4 feet to 6 feet high, and in large groups their feathery heads of blossoms will prove ornamental. All the kinds just named are of free growth, and may readily be increased by division of the roots just as growth commences in early spring. Any of those above named may be turned to good account by being well placed among shrubs in large groups for effect. If employed in the herbaceous border, they should be kept at the back by reason of their height. Among the dwarf kinds worthy of a place in the front row of the border or in the rock garden are

*T. ALPINUM*, a species with few flowers and four purplish sepals. The plant is rarely more than 8 inches or 10 inches high, and has a tendency to produce stoloniferous stems. Native of Britain, North America, &c.

*T. ANEMONOIDES* is a frail, elegant and dainty species not more than 4 inches high, with white blossoms nearly 1 inch across. If grown in the open ground, a sheltered shady spot in moist, peaty soil should be selected, and when in flower its delicate blossoms are worth protecting. It may, however, be well grown in large pans in a cool frame, and in this way may receive protection. There is a double-flowered form of this plant requiring the same treatment. It is worthy of note that shade and moisture appear more essential in the cultivation of these two kinds than to the majority, as they quickly scorch in full sunlight.

*T. MINUS* is another very desirable species, and includes some of the most beautiful and useful of the dwarf-growing members of this group. Some of the forms very much resemble the well-known Maiden-hair Fern, and conspicuous among these is the kind grown in our gardens as *T. adiantifolium*. This is invaluable either as a pot plant or for forming small groups in the rock garden. The foliage in a cut state is especially useful for mixing with flowers, and is worth growing on a large scale for this particular purpose. The plant is perfectly hardy, but its elegant Fern-like foliage is more quickly produced by frame culture. It succeeds well in any good sandy loam, though by no means particular as to soil or situation.

Another very charming plant, and from a decorative point of view perhaps the best, is

*T. AQUILEGIFOLIUM*, the feathered or tufted Columbine. In flower this is extremely showy and sure to attract attention, and when seen in well-established groups the corymbose panicles are very striking and the foliage handsome and distinct. There are several well-marked varieties of this: *T. a. rubrum*, with its feathery masses of crimson; *T. a. atro-purpureum*, *T. a. formosum*, *T. a. roseum*, all well worthy of cultivation. These kinds grow well in sandy loam fairly rich, and should be left alone for a few years to become well established.

Some of the varieties above named are very scarce at present, and it may be some years before they are at all plentiful, as they are somewhat slow of increase.

E. J.

**Daffodil Grandis or Grandee** is, in my estimation, the best of the bicolor varieties. It is rather later than *Empress*, and under good culture has finer blooms than either that variety or *Horsfieldi*. I fancy that this Daffodil is comparatively unknown, for I rarely see it mentioned, and until I grew it myself I was not aware that we had a white-winged variety that could compare with *Empress* or *Horsfieldi*. Can anyone say where

*Thalictrum aquilegifolium.*

and by whom Grandis was raised? Probably it is a seedling from Horsfieldi, and being considerably later in coming into bloom than that favourite kind, has attracted much less notice. In any case it is very valuable as forming a succession to these grand bicolor kinds, which are so highly prized by both the amateur and the grower for profit. This variety, Queen of Spain, abscissus and Mme. Krelage were in bloom with me at one and the same time, abscissus being rather later than the others in expanding its blooms.—J. C. B.

## THE ROCK GARDEN.

### VIII.

MAY 15.—The temperature during the past fortnight has been much warmer than usual at this time of the year. May 1 was the last of our rainy days here, and since then the sun has been shining so brilliantly, that in spite of the backward season many rock plants have opened into bloom almost before their usual time.

### THE WATER GARDEN.

The water garden is already aglow with the bright colours of Nymphaeas, which, although planted only twelve months ago, are already well established. Among the choicest of the varieties now in bloom is the lovely deep crimson Nymphaea Leydekeri rosea. Close by, Nymphaea pygmaea alba is looking quite at home. The small white flowers of this variety have a deep yellow centre and are very striking. Nymphaea Marliacea carnea is also fully expanded, and its very large flesh-coloured flowers form a delightful contrast to those of the other varieties mentioned. Another Nymphaea now blooming is Nymphaea Marliacea rosea with large delicate pink blossoms. A plant of the well-known Aponogeton distachyon is also blooming, and its fragrance is delightful. The pond in which these Water Lilies are blooming was made of concrete, and masked with grassy banks and rocks as described in my previous articles on the subject of constructing ponds in the rock garden. It is about 2 feet deep, and contains specially constructed large packets filled with rich soil about 1 foot below the surface of the water. That this situation suits the requirements of the Water Lilies is proved by their flourishing condition and the abundance of their blossoms in spite of the exceptionally severe winter.

### BOLD EFFECTS.

For bold effects the plants employed must either be themselves of considerable size, or otherwise they must be grouped in masses. I will name some of the principal larger kinds of rock plants suitable for this purpose, confining the list only to such as I have observed in bloom during this and the previous week.

*Rubus deliciosus* is in full bloom at Newton Abbot, where its long arching branches hang over a projecting rock, and, laden with large white blossoms, presents a beautiful picture. Close by is another bold effect, produced by a mass of *Centaureas* hanging down over the ledges of a large rock. Those in bloom are *Centaurea montana* (blue), *C. m. alba*, *C. m. rosea* and *C. m. sulphurea*. The last, by the way, is misnamed, as its flowers are not sulphur-yellow—as the name would imply—but creamy-white. The deep yellow *Centaurea macrocephala* does not bloom till later.

*Lithospermum purpureo-ceruleum* on a rock by itself is also most effective. In such a position its loose, pendent branches can fall gracefully over the stones without doing harm to other plants. The same might be said of the *Helianthemums* now blooming in the same rock garden. In a well-drained sunny position

where these are covering the face of a large rock they have not suffered during the severe frost, but where planted on moister flat ground they have been killed. The following are now blooming together: *Helianthemum pilosum*, *H. roseum*, *H. venustum*, *H. praecox*, and a pretty species called Rosy Gem. The pink and the white kinds seem to have suffered less than the yellow ones. *Polemonium reptans*, with its handsome blue flowers, may be used with advantage for flat portions of larger rocks, where it is most effective. It forms an effective contrast to the large leathery leaves and pink flowers of *Megasea crassifolia* and *M. atro-purpurea*, or to the yellow flowers of *Chrysogonum virginianum*, all of which are blooming simultaneously. Under this section of plants for bold effects I might also mention such quick-growing kinds as do not attain any considerable height, but spread quickly into a large carpet, covering stones and soil alike, and from the fact of their being in bloom together might form most effective combinations of colour and foliage as long as they are kept away far enough from choicer plants of slower growth. *Aubrietias* are not yet past, and the large number of quickly spreading Saxifrages with white flowers associate well with them. Of other white flowers now blooming I will mention *Pyrethrum Tschihatsehewi*, the fast spreading Russian Daisy, and *Dianthus plumarius*. Iberises, too, would now have been in bloom if they had not been cut down by the late severe frost. A large and excellent pink carpet is formed by *Saponaria ocmoides splendens* and also by *Polygonum Brunonis*, which is here just opening, and the pale pink *Chrysanthemum Zawadskyi*. For a brilliant blue carpet none can surpass *Lithospermum prostratum*, which, unfortunately, has suffered during last winter in many places. For carpets of a mauve colour the most effective of all are the dwarf *Phloxes* in their various shades, some of them almost blue in colour. Of these I will only mention *Phlox setacea* "G. F. Wilson," *P. divaricata*, *P. Lindsayana*, and the numerous *P. adboroughiensis* varieties.

Eecter.

F. W. MEYER

(To be continued.)

### CHRISTMAS ROSES.

MR. JENKINS'S article on Christmas Roses in THE GARDEN for May 4 (page 311) is full of valuable information on the cultivation of these useful flowers, and I quite agree with him that August is the best month in which to transplant or divide them. In no part of the country are Christmas Roses grown so largely or so well as in the west of England; in most cases large clumps may be found that produce hundreds of blossoms in a year. The foliage of such plants is always large and handsome, and the leaf-stem will often measure 1 inch in circumference. Such specimens are, however, well cared for in regard to top-dressings of short manure in the summer and applications of manure water in dry weather. We have one very successful grower in this district who attends the local market; his practice is to take up and divide the plants some time in August, and he will pull huge specimens to pieces at that time and place the different parts in suitably-sized pots with impunity. The plants do not suffer in any way. As soon as potted they are placed on the shady side of a high hedge and remain there until there is danger of frost, when they are removed to a cold frame. Treated in this way the plants flower as well as anyone could wish.

A good way of protecting the flowers from rain and frost, in the case of plants that are growing in the open ground, is adopted in a private garden near here. With some well-moistened clay and bricks the gardener every autumn builds a temporary 4½-inch wall along each side and the

ends of a line of plants, and high enough for the flowers to rise without touching the glass frame with which they are covered. With two or three thicknesses of mats on the glass, one can quite understand that it must be a sharp frost to reach the interior of such a structure. The walls are left to protect the foliage as long as necessary, but they are taken away in the summer to allow the air to reach the plants.

Taunton.

J. C. CLARKE.

### HARDY FLOWERS AT OAKWOOD, WISLEY.

IT would be difficult to describe the change that has taken place in Mr. Wilson's Wisley garden during the last few years, and it would be quite impossible on paper to give anything more than an idea of the floral treasures it contains. Probably Oakwood is never more interesting than in the spring of the year. It is the time of the Primrose, which, as all know, has received through a series of years so much attention from Mr. Wilson. The thousands of plants covered with flowers, displaying every tint that can be found in this flower, are alone worth a long journey to see. Among them Oakwood Blue is, of course, conspicuous, but some of the brighter tints are very striking. Few flowers vary so much from seed as the Primrose, and this great variability stands in the way of quickly increasing any of the finer forms of this flower. This can be easily seen when looking over beds of plants raised from Oakwood Blue, wherein flowers resembling those of the parent are comparatively scarce. These shades of blue varying much in intensity are, however, very beautiful and form a fine contrast to the crimson, bright red and other intermediate shades. Auriculas, so much neglected at the present time, are, I was pleased to see, getting a fair amount of attention at Oakwood. I noted that some very lively mauve tints approaching blue prevailed among them. I do not see that a really blue Auricula is out of the range of possibility. As before mentioned, the aspect of Oakwood has been changed during the last few years—so much so, indeed, as to be scarcely recognisable to anyone who has not seen it for some time. Ten years ago the greater portion was a wild garden pure and simple, but this has been changed, though in such a manner that whilst the needs of each plant are well provided for, the natural features of the place are rather heightened than destroyed. Oakwood now consists of, so to say, a series of gardens differing from each other both as regards general appearance and the character of their occupants. Therein the spade, fork and hoe are almost unknown, the cultural system apparently consisting in creating suitable conditions, placing the plants there, and allowing them to grow as they would in their native haunts, the attention given consisting merely in pulling out weeds and keeping rampant growing things within due bounds. In this way there is of course no root disturbance, and low growing things such as the dwarf *Phloxes* spread and carpet the soil. When some years ago this way of growing hardy flowers was advocated in THE GARDEN, I must confess to having been somewhat sceptical, and those who like myself have been doubters, would, on visiting Oakwood, have to admit that under certain conditions at least successful results can be worked out in this way. At the same time I should be sorry to advise anyone not having a good knowledge of hardy flowers to attempt this form of culture except on a small scale.

In a garden containing thousands of species, and many of them in bloom, it is rather difficult in a hurried visit to select any for special mention. Nothing in the place, however, gave me greater delight than a little colony of *Erythronium grandiflorum*. There is something wonderfully attractive about this flower springing from the natural leaf deposit in a moist place in the wood, and looking just as one would imagine it does in its native wilds. It is worth growing for its pretty variegated foliage alone, which in substance and coloration reminds one of *Phalenopsis Schilleriana*.

Where this grows plentifully—as I suppose it does in its native land—it must in its blooming time form a charming picture. No greater contrast to this modest denizen of the woods can be found than the brilliant *Tulipa Greigi*—too gaudy perhaps for some, but probably the most showy flower of spring, and one which is sure to attract attention. It is placed where it gets a maximum of sun heat, necessary for the due maturation of the bulbs. *Primula nivalis* and *P. viseosa* are in fine condition, and I never before realised their decorative worth. They grow and bloom as freely at Oakwood as the common *Auriculas*, and thus grown they are among the finest of spring flowers. They are placed in one of the most exposed positions in the garden, where they catch the breeze and sunshine, and they like their home. The Prophet Flower (*Arnebia echioides*) is apparently quite at home, and *Shortia galacifolia*, at the base of a tree in the wood, has, seemingly, come to stay. It is a neat-growing little thing with pure white flowers, but, I imagine, must have time to show its true form. *Epigaea repens* enjoys such robust health at Wisley, that I failed at first glance to recognise it. It is at its best in a damp place at the foot of evergreens, and I should doubt if it could be found in a higher state of vigour in its own country. The foliage is broad and glows with health, bred evidently of the congenial atmospheric conditions. *Daphne Blagayana*, so difficult to please, is in excellent condition, the foliage rich of hue and flowers numerous. It grows on a mound in full exposure. *Orobanchaceae* I must say a word for; it is a good thing, the colour of the flowers being attractive. I am not aware if any difficulties attend its culture, but I imagine that it only requires good loamy soil and fair drainage. Lenten Roses were going over, but by their vigour and abundant flower-stalks one could see how they love the partial shade and more or less humid atmosphere that prevail in some portions of the Wisley garden. And here let me give your readers the benefit of something, learned respecting this interesting family. It has frequently been remarked in *THE GARDEN* that the Lenten Roses, owing to the fact that the flowers fade so quickly, are useless for cutting. Mr. Tatnell, Mr. Wilson's gardener, overcomes this drawback in a very simple manner. Taking a flower, he made cross cuts at the base of the stem, when the segments immediately began to curl outwards. "Now," said he, "these will last as long as Christmas Roses," an assertion proved by the writer to be quite correct. I advise growers of Lenten Roses to make this experiment, and they will thus increase their affection for a very charming and interesting family of hardy flowers.

Daffodils at the time of my visit were one of the chief glories of Oakwood. They must be great favourites, for they are here, there and everywhere. One would naturally expect to see them well represented and in good condition, but I think that many like myself would be surprised at the vigour of such kinds as *Princeps* and *Empress*. To give your readers a fair idea I measured a bloom of the latter. It was  $\frac{4}{5}$  inches across the perianth. *Princeps* was correspondingly fine, with blooms almost as large as *Empress*, on stems nearly 2 feet high; indeed, I was not aware that this Daffodil could be brought to such dimensions. What I like about the *Narcissi* at Oakwood is the free way in which they are allowed to grow. One sees masses of them full of bloom. To all appearance they have been undisturbed for years, and they enjoy the repose. If flowers of such quality and in such quantity can be produced in this let-alone manner, what are we to say about the annual lifting that has been advocated in *THE GARDEN* and that is practised in some market gardens? One good gardener says, transplant annually on to fresh ground if you would have good blooms. Another tells us to divide every third year; but after seeing the masses of bloom both of the trumpet and star *Narcissi* at Wisley, one might conclude that this must be useless labour. Perhaps what may be necessary in one soil is not so in another. Emperor and Sir Watkin were in their finest form: the little *moschatus* and *cycla-*

mineus were doing very well, and some fine flowers of *W. Goldring* gave a true idea of the value of this variety.

Of the Lilies, Irises, and other things I may say that there is fair promise of a bounteous harvest of bloom, but of these I hope to have something to say at the proper time. J. CORNHILL.

## GIANT ASPHODELS.

(EREMURI.)

THESE noble hardy Asphodels are now becoming better known. They are natives of Central Asia and quite hardy in our country, but owing to their early growth, a well-drained, sunny, sheltered spot should be chosen for them. They are not plants for every garden, but many gardens have spots that would suit them. They do not like transplanting or root-disturbance, so previous to planting the soil should be thoroughly dug up. There are several species in cultivation, but one of the handsomest and the tallest is

*E. ROBUSTUS*. This kind has large tufts of long grassy leaves, which are of a dark glaucous green colour and about 4 feet in length and 2 inches or more in width. The flower-spike appears in June, and upon established plants grows 5 feet high, or even more before a bloom expands. It then continues growing and flowering for several weeks, producing hundreds of rosy blossoms and spikes quite 10 feet in height. What is evidently a form of this species is a very handsome kind named *nobilis*. It has shorter, broader leaves, a tall and noble spike of bloom, with flowers of the same colour as those of the preceding kind, but larger, broader, and of better form. It is quite distinct.

*E. BUNGEI* is one of the very best, and of this again, there are two distinct forms. The commoner produces flower-spikes about 3 feet in height, and only about 1 foot of the tip bears flowers, which appear in July. They are of a clear canary-yellow colour, with conspicuous orange stamens. The other form is identical in regard to colour and size of bloom, but the spike is taller and handsomer, as it attains 5 feet or more in height. Quite 2 feet of the upper part is crowded with splendid flowers. It is a rare variety, and there appears to be no general agreement as to its name. It is offered in the list of a good Dutch grower as *E. Bungei perfectus*. In leafage this species is much like a *Tritonia*. From the north of India comes

*E. HIMALAICUS*, which also blooms in summer, having spikes about a yard in height, bearing pure white flowers. All the kinds as yet in cultivation bloom in summer, with the exception of

*E. OLGEI*. This is an attractive kind, which only commences to flower late in August or early in September. It lasts well into the succeeding month. Its flower-spikes grow about 3 feet high, the lovely buds being of a clear peach-pink colour, and when expanded of a paler pink shade with conspicuous yellow anthers. There are other species known, but not yet much in cultivation.

A. II.

**Anemones and the frost.**—During the last few years I have raised thousands of the *St. Brigid* strain from seeds, and have at this time of year usually had a good show of bloom. In the autumn I had some thousands of roots, and I find that ninety per cent. are either killed or so injured, that they are worthless for this year at least. This is the first time I have ever known *Anemones* to be seriously injured, and were we likely to get winters similar to the past, we should have to adopt measures to guard the roots from extreme cold. It frequently happens that the foliage suffers during the winter, but this does not much matter if the roots and crowns are in good condition. On the return of mild weather new leaves are put forth and the plants soon lose

all traces of the hard weather. This spring, strong roots that are useful for supplying cut flowers, and that last spring yielded a succession of fine bloom during a period of two months, are almost flowerless. Large bulbs five and six years old have completely disappeared. No doubt a light covering of litter would have saved them, but I have always looked upon *Anemones* as so hardy, that protection of any kind would be superfluous. For the future I shall make a point of mulching with manure before the tubers break into growth, though, of course, this is not practicable with young seedlings, as they continue to make leaves all the summer and autumn.—J. C. B.

## *Tulipa Gesneriana* and other species.

—May I suggest through your columns the necessity there exists for the proper nomenclature of what are known as Tulip species? To my knowledge they are in endless confusion. I have now before me three or four self colours that certainly approach nearer to Mr. Baker's *macrospella* than to *Gesneriana*. The colours are eerie with white base, magenta with blue base, and a white self, growing to the same height as *macrospella*, all having the perfume of the latter, while *Gesneriana major* true is much taller, without any perfume, and an enormous flower. A minor form of this same *Gesneriana* comes from Holland that I would be inclined to name *macrospella major*. Then we have *Tulipa maculata* in two forms, major and minor, coming from the Dutch bulb farms, and a huge yellow flower, under the name *Jaune Pure*, that should be simply yellow *Gesneriana*. *Tulipa Billietiana* is also in confusion, coming as it does from some of the best firms as true, while from others it is simply the well-known *Golden Eagle*. The true *Billietiana* illustrates its character so distinctly in the leaf formation, that no one can be deceived; besides the bloom shows the red tinge when first opening, while *Golden Eagle* is a week or ten days in flower before its glorious blaze of scarlet and gold appears. I look upon *Golden Eagle* as a gorgeous Tulip for effect in huge masses. Then there are elongated sugar-leaf-shaped Tulips in flower now—self colours in terra-cotta with green base and orange with black base, deep crimson with jet black, and also pink striped and self yellow. In shape the buds are like those of the Parrot species, but the petals are smooth and not crimped like those of the Parrot Tulip, and all tall and May flowering. I would suggest that we should have a conference of Tulip species at Chiswick, where specimens could be sent in July by numbers from the old gardens of the United Kingdom, and let us get out of confusion. See what a conference did for the Daffodils, work now, I am sorry to see, at an end, yet a basis of operations that will hold good for years to come.—NEMO.

## ONCOCYCLUS IRISES.

I SEND you a gathering of *Oncoeyclus* and *Regelia* Irises. Among them you will recognise some old friends, such as *I. iberica*, *I. susiana*, &c., but there are others as well. The varieties of *I. Korolkowi* are especially beautiful, and some of them are quite new to me, such as *I. Korolkowi concolor* and *I. Korolkowi venosa*. If Mr. Balfour had not made it plain in his recently published book that there is no such thing in Nature as an objective standard of beauty, I should have put in a claim for them that they are in strictest accordance with it, but that is rather against my idea. As it is, I console myself with the thought which he allows to us, that they give a glimpse of something better than this world. *Iris Lorteti*, *I. Helena*, and some few others are, unfortunately, only conspicuous by their absence. This grievous calamity is entirely owing to the unexpected and desolating frost, which defied panes of glass and layers of mats, and cut to pieces the foliage which was still so promising in December; but to be forewarned is to be forearmed, and boards laid upon the frames after the fashion which prevails at Baden-Baden will prevent the recurrence of any such thing in the future and make my treasures safe.

As every year comes round I can only say of these *Oncocyclus* Irises that they seem to me to be more bewitching than ever. In their presence I can bid good-bye to *Narcissi*, *Anemones*, *Scillas*, &c., without a pang, but I should now like to hold the year back, or at any rate to moderate the pace with which my Irises are passing out of sight. Such delicate and ethereal refinement as they show cannot stand up against the fierce rays of a burning sun, and my special favourites will this season just come and go.

May 15.

H. EW BANK.

### FLOWER GARDEN NOTES.

**ANNUALS.**—So soon as annuals that have been sown either broadcast on beds to assist in the flower garden display or on prepared borders for cutting can be handled, they should be thinned out to the respective distances likely to be required to allow for the development of individual plants. It is a great mistake to let them remain crowded thickly together; the size and quality of the flowers are thereby seriously affected and the duration of bloom also considerably shortened. Where slugs are troublesome (and they seem very numerous this season, especially on beds and borders surrounded by Grass), it will be found advisable to mix up a goodly heap of fine wood ashes, adding thereto a fair proportion of soot, and dusting the beds all over with the same. Somewhat choicer annuals that were sown in frames on a slight hotbed will now be nice plants, and may be transferred to permanent quarters at any time. As East Lothian Stocks have wintered rather badly, the spring-sown batch of Stocks will be found very useful, especially those varieties of branching habit that are in request for the flower basket. *Cosmos bipinnatus* in different colours came in very acceptable last year for grouping at the back of borders, and the quantity sown in 1895 is, therefore, considerably increased. This is an annual of good habit, growing and flowering freely on rather poor soil, and having beautifully cut foliage as well as light, graceful flowers. Almost identical in height, but of a different shade of colour, is the new miniature Sunflower, an annual that makes a very effective group, holds its foliage well, and continues in flower until late in autumn. If bedding plants are rather scarce, one or two large beds may be filled with *Chrysanthemum tricolor* in variety. Very rich colours are obtainable in these *Chrysanthemums*, and, like the Sunflower, they bloom well until the end of the season. Dwarf annuals, such as *Petunias*, *Verbenas*, *Phlox Drummondii*, &c., that were sown early will, if they were pricked off into boxes or frames, now be nice plants, and they may be planted out at once, as they will bear more cold than *Geraniums*, *Fuchsias*, and the like. The remarks made above as to the depredations of slugs on outdoor-sown annuals will also be found applicable to those transferred from boxes or frames. Of all plants I think *Zinnias* are the first to suffer if the strain of these is a good one, and if they are planted near a harbour for slugs they must be carefully watched until they are well on the move, and remedial measures employed at the first sign of attack. If it is proposed to increase the stock of herbaceous plants from seed, boxes cleared of summer bedding stuff may be prepared for their reception. I recommend sowing in boxes rather than out in the open, allowing the boxes to remain in a cold frame until the seedlings are fairly well advanced. One is more certain of a good start in this way, and this is a consideration if seed is both scarce and expensive. The boxes should stand on a good bed of coal ashes to prevent the ingress of worms.

**HERBACEOUS BORDERS.**—There is every indication that there will be a very fine display in these borders. Plants grew away remarkably well all through the late summer and autumn of 1894, and there was a wonderful difference in their appearance at the end of that season and at the corresponding time in 1893, the protracted drought of the preceding summer having seri-

ously crippled many things on light, rather dry soils. It says much for the value of this race of plants that they were very little affected by the exceptional weather of last February. From the dwarfiest *Violas* and *Campanulas*, the *Pinks* and *Veronicas* on the front of borders, to the tall *Sunflowers*, *Starworts*, and other things of similar height at the back, all may be pronounced perfectly hardy. I have lost *Zauschneria californica*, a considerable number of *Montbretias*, part of a batch of *Gypsophila paniculata*, and last, though by no means least, all the large clumps of *Fuchsia Riccartoni*, *F. gracilis* and *F. globosa*, which had been many years in the same spot. I blame myself now for not mulching them heavily, but there was no apparent necessity, as they had never suffered before even in very severe winters. What is the experience of GARDEN readers with *Arundo conspicua*? I find my clumps are killed, although they were staked and tied up. The true *Pampas* (*Cyperium argenteum*) has, however, come through safely, but is considerably crippled. Referring back to those things that are so much better this year than at the same time in 1894, it will be found that it is peculiarly the case with species or varieties of the same that are at their best in a fairly moist spot, and that suffer proportionately from protracted drought. On light dry soils the annual heavy surface mulching is one of the chief essentials towards the successful culture of such plants.

**SPRING FOLIAGE.**—From the time that so many things in the way of tree and shrub life came to be recognised as important features in flower garden work, the many and varied forms of foliage have been of considerable interest. I notice that the exotic trees and shrubs that are as a rule late in showing leaf are this year even later than usual. Indigenous trees have put on their spring dress, but at the present time (May 10) the only sign of life in such things as the deciduous Cypress, the Kentucky Coffee Tree, and in shrubs the Virginian Fringe Tree and *Asimina triloba* is a plumping of the buds. One of the finest things in the way of foliage just at present is furnished by the Copper Beech, backed by large specimens of the common Beech and flanked by Larches. I saw this bit of tree life the other evening with the rays of the setting sun shining full upon it, and the glowing tints were simply indescribable. *Prunus Pissardi* and *Cornus brachyoda* are as effective when contrasted with green shrubs of similar height as is the Copper Beech with trees of larger growth. It may be well to give the reminder in connection with flower garden work that there are many hardy trees possessing foliage of such unique character as to admit of their use in sub-tropical gardening where large Palms and *Bracenas* are not available. Young plants of the Umbrella Magnolia, of *Ailanthus glandulosa*, of *Pyrus Sorbus*, and nice sized plants of *Azara microphylla* may be mentioned as suitable subjects, whilst, given suitable soil and situation, there are no better things than the tallest and most graceful members of the Bamboo family.

E. BURELL.

**A note from Langport.**—My garden is looking better than ever at this season of *Paeonies*. Despite the severest winter I ever knew, the Tree *Paeonies* and the early herbaceous sorts are just now in perfection, as also are *Magnolia Lenoé*, scarlet Chestnuts, *Gentianellas*, Siebold's double-blossomed Cherry, *Cydonia Simoni*, and the various Lilies. *Rhodotypos kerrioides* is now covered with flowers like Orange blossom. *Rubus deliciosus*, *Aquilegia cerulea* from the Rocky Mountains with flowers 3 inches across, Grape Hyacinths and yellow Banksian Roses are all in bloom. *Akebia quinata*, with racemes of flowers, and growing against a white lias wall, is very attractive. Alpine *Phloxes* (white and pink), *Iris paradoxa*, *floribunda*, *olbiensis alba*, *Fontarabia* and Mrs. Gretton, the yellow *Asphodel*, the white, red and blue *Centauras*, Iceland Poppies, *Leichtlin's Aubrietia*, *Myosotis alpestris*, *Globularia trichosantha*, tufted *Pansies*, Fairy Apples, *Wistaria*,

the large heart-leaved *Saxifrage*, with spikes of rosy purple, and an alpine variety covered with crimson flowers, the crimson and yellow-flowered *Genista Andreana*, *Lily of the Valley*, *Berberis stenophylla*, the common *Barberry* and single-flowered *Pyrethrums* are also flowering freely; all growing in common soil about 1 foot deep on a bed of gravel. In dry weather in summer the soil bakes as hard as a stone, and when wet it sticks to one's boots like bird-lime. The broad-leaved *Aponogeton* covers the water in the pond with its flowers. All have been in the open during the winter without protection. The Japanese Wineberry is quite hardy and is growing fast. The Scotch Thistle is growing apace; it already has leaves 2 feet in length covered with a white down. Hollyhocks amongst the shrubs are growing fast; those in the fields were all killed. I have known the *Laurustinus* and *Laurcls* killed to the ground, but although their leaves were browned, the wood was not injured. Some of the *Pines* and *Junipers*, *Cupressus macrocarpa*, *Bays*, *Arbutus*, *Berberis japonica* and *B. stenophylla* are browned and *Roses* are killed to the ground. *Iris reticulata*, *Crocuses* and *Snowdrops* bloomed as freely as ever as soon as the hard frost was over, and the *Tulips* and *Hyacinths* followed. The *Gaillardias* are all coming up strongly, which proves them perfectly hardy. We registered zero Fahr., which is 4 below any record in this parish. My Peaches, Apricots and Pears are well set with fruit, and the blossom in the Apple orchards throughout this county is the grandest sight I ever remember.—WM. KELWAY.

## GARDEN FLORA.

### PLATE 1015.

#### SINGLE CHRYSANTHEMUMS.

(WITH A COLOURED PLATE OF (1) MISS ROSE AND (2) MARY ANDERSON.\*)

TWELVE or thirteen years ago Messrs. Henry Cannell and Sons, of Swanley, announced the distribution of some new *Chrysanthemums*, which were at the time regarded as a new departure by the growers of that popular flower. These were some single-flowered varieties, and hopes were entertained to a very large extent that they would occupy an important place at our shows. On various occasions, however, encouragement has been offered to the growers of single *Chrysanthemums*, but the exhibitor's eye has been so trained and the visitors to shows are so accustomed to see the large massive blooms of the other sections, that it is well-nigh hopeless for the most ardent lover of the single type to expect them to occupy any satisfactory position at all on the tables at our November exhibitions.

But for other purposes the single *Chrysanthemum* is pre-eminently adapted. Where free-flowering, bushy plants with abundance of colour are required late in the year, or where cut flowers in profusion are required for vases, epergnes, bouquets, &c., either separately or in conjunction with others, the single *Chrysanthemums* will come in most acceptably. In form they are varied; the colours are mostly attractive, and the light, stary flowers are capable of being set up in artistic combinations by those who desire to make use of such material. As a matter of fact, many of these single flowers are more pleasing to the eye thus used than poorly grown, undeveloped blooms of some of the large exhibition types.

In former issues THE GARDEN has given several different forms. America, a long-

\* Drawn for THE GARDEN in the Royal Gardens, Kew, Nov. 12, 1894, by H. G. Moon. Lithographed and printed by Guillaume Severcyus.

petalled Japanese single, Jane, both white and yellow, and Lady Brooke, a small yellow variety, have been the subjects of coloured illustrations in THE GARDEN. One of the most attractive groups of single Chrysanthemums figured in the horticultural press appeared in the *Revue Horticole* five years ago, but, unfortunately, without the names of the varieties being given. They were pretty, bright-coloured Marguerite-like flowers, that do not appear to have found their way into this country.

The cultivation of single Chrysanthemums presents little or no difficulty, and to ensure the most satisfactory results, the natural in contradistinction to the ordinary method for show should be practised. Either in the open border or in pots they are effective and of much use during their season.

Mary Anderson and Miss Rose, which have been selected for illustration, are two very well-known varieties, and much appreciated by those interested in singles. They were amongst the earliest introductions we had, and, I believe, both raised by Mr. C. L. Teesdale early in the last decade. They were sent out by Messrs. Cannell and Sons in the spring of 1885.

C. H. P.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**EARLY PEACH HOUSE.**—The fruit from the earliest kinds, such as Alexander, Amsden June, and other Peaches, being mostly gathered, it may not be out of place to give a few details as to the ripening of the new wood. Such varieties as fail to set freely and drop their buds badly are the kinds which are specially referred to, as I find they require different treatment to our home-raised varieties. Last season we had scarcely any buds drop; even the variety Alexander behaved well. This I attributed to the roasting the trees received in 1893, the summer being so hot. After the fruit is gathered it is well to cut away useless wood. This will give the new wood laid in for next year's fruit more room and encourage thorough ripening. If the early kinds are in a separate house there is less trouble, as the trees can be treated as required, but if the house has been kept cool and rather dry to obtain fruit of good flavour, such treatment should not continue longer than necessary. In many gardens early and late trees are in one house, but the trees just over should now be encouraged to continue free healthy growth by syringing daily, closing early and maintaining a moist atmosphere. The trees with fruit just ripening will require to be kept dry overhead with more air, but those now over require moisture in abundance and the growths kept clear of red spider. The young wood should now receive more attention in the way of tying in to get it well matured, and the borders should also get water and food in the way of liquid manure, with a mulch to retain moisture; this latter will go a long way to keep down spider, and on poor or light soils the mulch damped over at night will cause new surface roots.

**SUCCESSIONAL HOUSES** will now be making good progress, and fruit in those started early in the year will be over the stoning period and taking on the last swelling. The fruits should be freely exposed to all the sunshine and light that can reach them, so that they may colour freely and get flavour. Many fruits are so much covered by leaves that it will be necessary to remove a portion, and shoots may be regulated or tied back for a time to give the fruit more light. Fruits on the under side of the trellis may be lifted by ties or small sticks and given more light. Now is a suitable time to apply food to these trees either in a liquid state or otherwise. Do the work thoroughly, as when the fruits are a little more advanced there is no opportunity of giving

food, and water also must be given sparingly. Shoots for extension of main branches should be loosely tied in position, kept clean, and free of the glass, which soon cripples growth. Avoid hard tying in of next season's bearing wood till a later date, as advised above. Placing nets to catch the fruit in houses just finishing is, I consider, useless, as a Peach in a soft, fully ripened state when it falls is much bruised. It is much better to go over the trees early in the day, and anyone with a knowledge of ripe fruit can see at a glance what fruits will part readily from the tree. The temperature for this house may now be 65° at night and 10° higher by day, with ample supplies of moisture in all parts of the house till the fruits soften, then more air with less moisture and only a little warmth in the pipes to maintain an even temperature are necessary.

**LATE HOUSES.**—Thinning the fruits and removing useless wood will be the necessary work, and as these trees receive more natural treatment, it is well to thin freely, selecting the larger number on the upper portion of the trellis, as these get more colour and attain to greater size. In thinning, it is well to study the growth of each variety, as some of our old favourites drop their fruits more during the latter part of their growth. The shoots will now require a final going over, thinning them where much crowded. The shoots from joints where fruit is left to mature should be stopped at the fourth joint; this is better than total removal, as it then assists in swelling up the fruit and does not arrest the flow of sap. With the thermometer outside standing at 65° at night, to advise on a fixed temperature would be out of the question, but sudden fluctuations must be guarded against. With rain or cold winds mildew will soon make its appearance, and a genial, growing atmosphere should be maintained.

**ORCHARD HOUSE.**—With summer weather work in this house will increase in the way of supplying adequate moisture, and my remarks a few weeks back with regard to mulching now apply with more force, as with insufficient water the fruits will cease to swell, and when ripe will be acid and the colour poor. Such fruits as Peaches and Nectarines in pots require much the same treatment as advised above, but more attention in stopping and thinning, as over-cropping will end in total loss. Other trees in pots, such as Cherries, Plums or Pears, need even more care. Cherries will now be so far advanced as to need different treatment to other fruits, and may be removed to a cooler house or sheltered corner. Later fruits just showing colour will need more moisture, and should now be thinned freely to get large-sized examples of the best quality. Trees in small pots may with advantage be allowed to root out freely, but such trees cannot be moved from place to place, so that it is well to depend mostly upon surface dressings, liquid manure and other quick-acting foods. Young trees will require more freedom, but it is well to stop early and often. Much the same culture is necessary for pot trees as advised for late Peaches, but more pinching of strong shoots is necessary, and in stopping, the reverse is required in pot culture, as the shoot at the base of the fruit must be allowed free growth, this being the fruiting wood as regards Peaches and Nectarines for next year. The syringe must be used freely twice a day, thoroughly moistening the trees in all parts of the house. The growth is much stronger if a little air is left on the ventilators at night, opening after sunset, but closing and damping as usual in the afternoon. Strawberries in pots in mixed houses are troublesome at this season. It is well to get rid of them at the earliest moment possible, or spider will play sad havoc with the fruit trees, though by a free use of the syringe the pest can be kept down, cold frames being best for the Strawberries. Green fly will perhaps be troublesome; this must be got rid of as soon as detected, fumigating several evenings in succession and syringing freely next morning.

**STRAWBERRIES.**—The season for forced fruit is now drawing to a close and there should be no delay, when any plants have been cleared of their

fruit, in thoroughly washing down all shelves and dressing walls with fresh lime, using a portion of sulphur in the limewash, as, no matter how much care was taken in keeping the plants clean, with hot weather red spider will soon spread rapidly. There is often a want of fruit at the end of May and early in June, and for that period I have advised cool frames. The plants stood on a hard coal ash bottom finish better and can be kept much cleaner. Such varieties as Sir J. Paxton and Sir C. Napier are the best for late work; the latter is less subject to red spider, and both are almost mildew-proof if not over-watered. Plants plunged in manure beds will require less moisture, but maintain a free circulation and warmth in the pipes, as such plants with sudden changes of weather are soon affected by mildew. The planting of forced plants for autumn supplies should not be longer delayed, planting firmly in good soil, deeply dug and liberally manured, not allowing the plants to suffer from want of moisture, it being a good plan to damp overhead in the evening and to remove the flower-spikes as they appear till required for a crop.

G. WYTHES.

### THE KITCHEN GARDEN.

**PLANTING VEGETABLE MARROWS.**—In many places the earliest Potato frames will have been cleared of the crop, and thus an opportunity afforded of getting the earliest Marrows transplanted. The Potato soil will afford a good rooting medium without any addition of manure at present, a little stimulant being easily given later on when the plants are in full yield. If the soil is at all dry, give a thorough soaking the day before, the plants themselves also being all the better for the same treatment. In planting do not sink the collars too deeply in the soil, or basal rot is liable to ensue, and in order to avoid the necessity of too frequent waterings at first, mulch for a foot or so round the stems with spent Mushroom manure. All blooms on the plants should be removed, one plant to a light being ample. Syringe overhead on fine afternoons until established, airing cautiously at first and liberally when growth has freely commenced. Those that are to be planted in second early Potato frames must not be allowed to suffer from want of pot room or nourishment, a little sprinkling of guano or fish manure doing much towards keeping the plants in a growing condition if in small pots and not wanted for another week or so.

**GLOBE ARTICHOKE.**—It may now be seen in what condition the stools of these are, as growth is somewhat advanced. Sometimes when much weakened by frost a colony of tiny offsets appears round the plants. It is not advisable to allow all of these to remain even if not wanted for filling up blanks or for potting. The weakest and most distant of them should be removed, and about half-a-dozen of the strongest and nearest home allowed to remain. There will be greater need than usual this summer for feeding Globe Artichokes. This may be done either by pouring farmyard liquid over a good thick mulching of cow manure, or by frequent applications of fish manure or guano sown around the plants during showery weather. Hoeing and stirring the soil around and between the plants are also highly beneficial. In March I advised those who had lost most of their old stools to take up a portion of the young offsets and pot them, afterwards giving them frame protection with the ultimate view of transplanting them. These should now be of good size, and may be put out towards the end of the month. Prepare the ground liberally, plant carefully, and mulch heavily for some distance round the base, as it is astonishing how these subjects root out when once they get established and what an immense amount of feeding they will take. When plants raised from seed are fit for transplanting, an odd piece of ground should be selected, as so many being of a worthless character it would be folly to plant them where they are to remain. On an odd plot the seedlings can be planted thickly and the good ones only retained.

**SEAKALE.**—The sets inserted some time ago for the main forcing batch now being somewhat advanced in top growth should be gone through, and the new crowns reduced to about a couple on each set. Some leave more, and, indeed, others never thin at all, but the practice is ruinous, as no sun or air can gain admission, and weak, puny produce utterly unfit for forcing is the result. After reducing the crowns give a broadcast sowing of a good fertiliser and use the Dutch hoe freely to keep down weeds. It is a good plan on light soils to give a good mulch of some light material to conserve the moisture. Nothing surpasses that oft-recommended material, old Mushroom manure. All coverings, even from the latest assisted roots, must now be removed, and any that are to remain another season must have their growths also reduced in number. The ground amongst those that were covered with pots and leaves must be pricked over with a fork, and either short rich manure worked in or a good surface mulch given later on.

**NEWLY-PLANTED RHUBARB.**—Where new plantations of Rhubarb were formed this season, and early kinds were given a sunny position and warm soil in order to encourage early growth and ripening of the crowns for forcing, a good thick mulch must be given and water supplied to the roots, as many new fibres will now be at work. Upon no account pull any from these this season, as this would greatly weaken the crowns before they get established. If any seed-stems appear, remove them at once, as these also weaken the roots. The same remark applies to old-established beds, as seed-stems are extra troublesome this season. Where any choice kind that was forced has been gradually hardening off under some protecting material, it may now be finally planted in the permanent bed and allowed a three years' growth before again being forced.

**LIQUID MANURE.**—There will now be plenty of subjects in full growth that this stimulant will suit better than all others, such, for instance, as successional batches of Cabbage, hand-light and other Cauliflowers, and Tripoli Onions. In applying it be sure to dilute it sufficiently if from a tank or well, and take care not to water the plants overhead. After applying the manure water, go over the beds with pure water, using a rose to cleanse the foliage from any that may have lodged upon it, and to wash any remaining sediment well into the ground. A good watering with this once every fortnight will do a deal of good to any of the foregoing crops.

J. CRAWFORD.

## CHRYSANTHEMUMS.

### DEPTH IN CHRYSANTHEMUM BLOOMS.

MR. MOLYNEUX has apparently overlooked the origin of this discussion. In writing under the heading of "Chrysanthemums for the New Year" I happened to express a dislike to "mere lumpiness" in a Chrysanthemum bloom, simply expressing in this a personal opinion without any idea of criticising the opinions of other people. This opinion Mr. Douglas was good enough to notice and to criticise, being careful at the same time to leave us in doubt as to his own taste, and contenting himself with telling us that "the best judges" give good points for depth. With much that Mr. Molyneux advances I cordially agree, especially as to the merits of the three varieties he names, the last of which (Duchess of York) I have not, however, grown or seen except in an illustration. These or any other drooping petalled varieties are not, in spite of their size, what I call lumpy. I feel grateful to Mr. Molyneux for giving us the points which judges keep in view when judging. Most of these points, taken individually, are admirable. Taken as a whole, however, I contend that they are leading to the production and to the retention of new varieties far less beautiful than many that are fast being supplanted from want of one or other

of these fixed points. One does not need to be told that added depth, breadth of petal, and solidity of bloom mean higher cultivation, but the question I have in view is, do these things mean added beauty in the majority of cases? If not, why seek after them?

Taking these points singly, first we have

**SIZE.**—Surely there should be a limit even to this. Is Mrs. C. Harman-Payne a type of beauty? And yet we are told by Mr. Shoemith that "it is among the first dozen seen most often in exhibition stands." Mr. Shoemith goes on to say, "Apart from its size, however, there is nothing to recommend it unless it be that it is one of the easiest to grow." Duke of York, too, is said in the same article to be a very popular exhibition variety, "dull and uncertain in colour, with very little character in its formation; it has gigantic size." It "may be made to produce blooms, perhaps not altogether repulsive, by late bud-selection." Strong words these, and I would commend the whole article, which may be found in your issue for February 16, to those interested in the subject.

**DEPTH.**—This being the original point of discussion, I may be allowed to say that I incline to the opinion that the depth of a Japanese Chrysanthemum should not much exceed one half its diameter, measuring from the base of the bracts, and always excepting those varieties whose petals droop naturally, as these cannot possibly be included as lumpy. Anything exceeding this appears to me to spoil the symmetry of the flower.

**SOLIDITY.**—This may be overdone. Some of our most charming varieties are far from solid.

**BREADTH OF FLORET.**—Not necessarily a gain of beauty. If broad, strap-shaped petals are desirable, Mr. Molyneux is unfortunate in having selected three comparatively narrow-petalled varieties, one of them especially so, as types of elegance. The tendency is to get varieties with the breadth of petal of a Cactus Dahlia plus the solidity of a show Dahlia.

**SYMMETRY.**—An indefinite point which must be a matter for individual taste.

**FRESHNESS—COLOUR.**—These may pass without comment.

**COARSENESS OF FLORET.**—I never before saw this advanced as a point of merit. Probably the converse is intended, though one has one's doubts about it when one remembers the coarse-petalled varieties so often seen.

**CONTOUR.**—Might fairly be included with symmetry.

**WELL-FILLED CENTRES.**—There is no necessity for over-filling them at the risk of spoiling the grace of form.

**CONSISTENCY OF FORM WITH THE VARIETY.**—This, I take it, should be the essence of the whole matter. If this point had its due weight, exhibitors would not need to hesitate about including old varieties which have been retained and valued at home, but which would have no weight on the show board under the existing régime.

**DIFFICULTY OF CULTIVATION.**—With this I entirely disagree. It is simply a bolstering up of varieties which, unless they have some exceptional and peculiar merit, should give way for others without this defect. Often enough the inability to grow certain varieties of delicate constitution up to their best form arises from circumstances beyond the control of the grower. Apart from the quality of the flowers when compared with other varieties, the demerits of a plant should never add weight in favour of its flowers when being judged. It is putting a premium on a bad constitution. They may be, to the initiated, wonderful examples of skill and of difficulties surmounted, but to the general public, from whom horticultural shows get their support, they have no enhanced value.

I am not sure that it would be so difficult as Mr. Molyneux imagines to add a point or two to those given by him, though one must needs have some amount of courage to do so. My first point would be in a negative direction, as it would tend to lower the number of points given in judging to flowers of inelegant form, and that

there are many such which now add greatly to the chances of winning prizes is beyond question. With the great wealth in variety that we now have, it reflects but little credit on those responsible that flowers with such little intrinsic beauty are to be found. While such things happen it is difficult to see where symmetry and contour come in. Would it not also be helpful to add "diversity of form" to the points given by Mr. Molyneux, of course eliminating all coarse and characterless varieties? I have, however, no wish nor vocation to make suggestions, and had no thought of doing so.

It is interesting and instructive to hear Mr. Molyneux's opinion of catalogue descriptions, and his wide experience must carry weight. I am glad to learn that the case is not so bad as it seems. The loss of character in some flowers of which I wrote and which had been unduly overgrown appears to me to be sufficiently consistent. Deep varieties they were naturally, and they had been made deeper and coarser by over-stimulation. If depth cannot be added by such means, what becomes of the Molyneux system of cultivation?

J. C. TALLACK.

## KITCHEN GARDEN.

### THE ASPARAGUS KNIFE.

AT page 325 of your issue of the 11th inst., in the able cultural directions then given as to Asparagus, the following passage occurs: "In forward localities cutting will now have become general. Some judgment is needed in this work, as if the knife is thrust too deeply down, &c." I have often wondered why a knife came to be used in gathering Asparagus. In my opinion one can gather Asparagus more quickly and better without a knife. By taking the young shoot gently between the forefinger and thumb of the right hand close to the surface of the bed, the shoot is easily severed and placed in the left hand, and one does the work very quickly. Here a young lad has gathered from 400 to 500 heads daily during the last week, and in no case has it taken over one hour to gather, wash, and tie up into bundles of fifty heads each. I have to produce an abundant supply of Asparagus daily while the season lasts, and after having tried various manures, I consider nothing so good as nitrate of soda and sulphate of ammonia mixed with wood ashes, all well mixed and passed through a half-inch sieve. A dressing in the first week of March and a second about the end of the first week in May keeps the beds going well into June, when cutting is discontinued. A mistake often made even now is putting a heavy covering of farm-yard manure over the beds in autumn, and in instances that have come under my notice 3 inches or more of soil above the coating of manure. Our beds here are all on a level. The spaces between the beds are as high as the beds, which I think very desirable, as the roots derive a great amount of nourishment from these spaces. When these are dug out to a depth of some inches (I have seen the centre of a bed 1 foot higher than the bottom of the alley) the principal feeders are cut off, the sides of the beds presenting an open surface for frost. It might justly be said that in many a garden root-pruning of Asparagus is done annually. I once took charge of some beds treated on the raised system, with alleys dug out and thrown on to the beds in autumn where Asparagus was never looked for until May. After reducing these beds and filling up the alleys, I cut Asparagus of the finest quality three weeks earlier the first season following; the beds produced a much greater quantity, and the quality ever so much better. Our beds

here are mulched in autumn before frost with long manure from the stables, not more than 2 inches or 3 inches in thickness, with no soil whatever over the mulching, and after all the severe frost we have had during the past winter the beds are producing quite as well this season as they have done during the last seven years.

I should have stated that early in March the mulching is taken off the beds. The bed is slightly pricked up with a garden fork, top-dressed with the manure already referred to, a sprinkling of soil being put on over all, the space between the beds forked over and as much of the mulching buried as can be got in, any that is long and strawy being put between the rows of Strawberries, so that none is wheeled away. I sprinkle the beds two or three times during the season with agricultural salt, more for retaining moisture and destroying slugs than for any manurial properties the salt contains.

A short time ago I was in a garden where the owner said to me, "Can you tell me how I do not manage to grow Asparagus?" The beds had been heavily covered with cow manure in autumn, and a thick coating of soil put over all. The alleys between these beds were like open drains, over a foot deep. On removing at least 9 inches of covering I found the Asparagus starting. Had these beds been treated as recommended, I have every reason to believe the owner would have had a daily supply of Asparagus from them since the middle of April, being a fine situation and the soil of a light gravelly nature. I started gathering Asparagus this season on April 20.

Stoke Park Gardens, Slough. D. KEMP.

\* \* \* With the above communication some remarkably fine heads of Asparagus were sent, showing that the treatment is in every way satisfactory.—Ed.

**Celeriac.**—This is a most useful vegetable and worthy of more extensive cultivation. If two batches are grown, the one for autumn and the other for winter use, the former may be used for flavouring, while the second batch, although similarly useful, will also serve as a vegetable for the dining-room. Some growers plant it out on the level by the margins of walks, but it deserves a better position than this in a good rich soil. I prefer a wide shallow trench and to dig in plenty of rich manure. Four rows may be planted in each trench, as earthing-up is not necessary, it being the root portion that is used. While growing, several copious drenchings of liquid manure should be given, in addition to which a mulch of Mushroom manure will help to retain the moisture. Anyone anxious to try it may still sow seed in a box or pan, growing the plants in a frame until they are fit for transplanting.—J.

**Late Peas.**—In northern localities, as a rule, the end of the month or during the first week in June is late enough for the final sowings of tall-growing late varieties, although up to the third week, or even the end of June, the small round-seeded sorts may be put in. Mildew is often such a scourge amongst late Peas, that one had better be a little earlier with them than incur the risk of total destruction. These remarks of course apply more strictly to rainy, low-lying localities. Further south, Ne Plus Ultra, British Queen, and Walker's Perpetual Bearer may safely be sown up to the second week in June, although even then freedom from mildew cannot be guaranteed. As these late crops are subject to much sun and wind, more care will be necessary in preparing for sowing and in after-treatment likewise. On shallow soils and at high elevations trenches are imperative. These should be taken out rather shallower than for Celery and plenty of good manure dug in. The seed should then be sown and sufficient soil returned to cover it nicely.

This will leave room for water and to apply a mulch should such be necessary. Those who with a good climate and soil can wait till the second week in June before sowing the latest crops will find Stourbridge Marrow and the well-known Criterion good varieties. Where tall sticks are difficult to obtain, Veitch's Autocrat and Sturdy are most convenient and profitable. Where the soil is hot and shallow, these trenches may with advantage be soaked with farmyard liquid once in ten days, as it is astonishing what a quantity of moisture the roots will assimilate when growth is healthy and strong.—J. C.

**Frame Cucumbers.**—Plants transferred to frames and pits in April will now be making free growth. Care will, however, be necessary for some little time in airing, covering at night with double mats and watering with warm water soon after noon on sunny days. When sun is absent, refrain from wetting the foliage, especially in the afternoon, and if any roots appear on the surface of the soil, add a little more sweet turfy compost and make it firm. Allow a sufficient number of main shoots to extend for the present, removing any that are weak or crowded. It is important that a little air be admitted before the temperature of the frames has risen too much from sun-heat. When this occurs and a volume of air is admitted suddenly, disastrous results often follow.—C. N.

**Bolting in Cabbages.**—Bolting amongst spring Cabbages appears to be very common this season. This is no doubt due to the unusually severe frost which followed the very mild open weather. Cabbages and other green vegetables grew with great freedom up to the new year, and when in a sappy condition were caught by the frost. The snow protected the autumn-planted batches of Cabbages, but the check given was considerable—so great, indeed, that bolting is the consequence. I think winters like the past prove more and more the necessity of planting several varieties of Cabbages in autumn instead of depending on one variety only. I must speak again in praise of that good old Cabbage, Ellam's, as although many plants of Earliest of All and Enfield Market, grown under exactly the same conditions and planted at the same time, have bolted with me, not one of Ellam's has done so. A considerable quantity of Early Rainham in one garden in this neighbourhood is quite free from bolting.—J. C., Newark.

**Seeds not germinating.**—There will be much disappointment this season in many kitchen and market gardens, as so much seed was sown before the ground was in a fit condition to receive it. After the snow and frost disappeared many were naturally anxious to get their earliest crops sown, but in many instances they would have been forwarder in the end by waiting a fortnight longer. In the case of Marrow Peas, many rotted where undue haste in sowing was indulged in. Sprouted Potatoes, again, that were planted before the soil had time to get warmed have come up very irregularly and weakly. By waiting until the sun's rays have had time to penetrate and warm the soil, and by repeated surface stirrings in the meantime, growth is not only quicker, but the yield much more profitable. Another point well worth the attention of all who desire early vegetables is working into the soil plenty of light opening material, such as leaf mould and potting shed refuse, at the same time raising the ground somewhat above the surrounding level. This course will work wonders in gardens which are not naturally warm and well drained.—C. H. N.

**The Potato crop.**—On early sheltered borders such Potatoes as Sharpe's Victor, Ringleader and Puritan will need attention in the matter of cleaning and earthing up. Choose a bright and if possible windy day to pass the Dutch hoe between the rows, and afterwards draw a moderate quantity only of soil up to the base of the haulm. On poor shallow soils apply a little artificial manure before earthing up, bearing in mind that we are not yet out of danger from frost, and that protection is necessary for some time longer. In

the case of my earliest batches, which I protect with troughs, I place a couple of bricks at each end of the rows. This raises the troughs and prevents them from injuring the haulm after earthing up. Of course where a framework and rough canvas are used there is little or no difficulty in the matter. Although full early under ordinary circumstances for watering Potato crops, a soaking may be found necessary on shallow warm soils, and the best time to apply it will be just as the tubers are forming and again when half grown.—C.

**Potato Ringleader.**—I am glad to hear "J. C." has found the above Potato so satisfactory. With me it is superior to Sharpe's Victor, which for two seasons I tried both in frames and in the open, and it was poor in the extreme. The soil here is heavy and retentive of moisture; therefore I think Victor requires a light soil. The best examples I have seen of it came from soil of that character.—E. MOLYNEUX.

**Mulching early Peas.**—As a rule the first early Peas are planted in the warmest corner of the garden and in a warm soil, the object being to secure a few pickings as quickly as possible. This being so, it sometimes becomes necessary to mulch and even to water to avoid a sudden collapse of the crop. Chelsea Gem is now in full flower and promises well. Before putting on the mulch of short manure, give a sprinkling of artificial manure; this will be washed down to the roots by occasional waterings and enable the pods to swell off. If this assistance is denied the crop in dry windy weather, the secondary blooms sometimes fail to set at all. If William the First, Exonian, or any of the second earlies show a tendency to grow instead of to flower, they may be urged into fertility by pinching out the leading growths, and when well furnished with bloom may be assisted in the same way as advised for the earlier crops.—J. C.

**Late Broad Beans.** Where these are esteemed after July, extra trouble is necessary to ensure a crop, as if not favoured with a somewhat shady situation, a cool and somewhat heavy soil, and plenty of nourishment, the foliage not only falls a victim to black aphid and becomes at once sickly, but the Beans are tough and uneatable. An east or, if obtainable, a north border is best, or, failing these, a plot of ground somewhat shaded by trees will answer fairly well, and even here, if time can be spared, the crops will be greatly benefited when in full growth by applications of liquid from the cow yard. For present sowing none, I think, can surpass Bunyard's Longpod, and where colour is a desideratum Green Windor will answer the purpose well. Beck's Green Gem is a capital Bean for shallow soils if sown at this date, it being dwarf, a capital bearer, and the beans of good colour and tender.—J.

**Tomato Ladybird.**—For free cropping few varieties can equal the above. I have now grown it for two seasons and find it all that was stated when sent out. It is interesting to read such notes as those of "J. C." His being quite a different locality to where this Tomato was raised, shows it is reliable in other places. It is strange that a variety highly recommended for winter fruiting should be one of our best outdoor kinds. This is readily understood, as a variety which sets so freely in winter often does well under adverse circumstances in the open. "J. C." does not advise this variety for open-air culture, but I can recommend it with every confidence. As regards quality, it was the best with me in 1894.—W.

**Sowing Runner Beans: a new method.**—This being the season for sowing runner Beans, I should like to suggest a method of growing them instead of the usual conventional rows. This is to sow the Beans in circles of 4 feet in diameter. I have practised the plan for some years, and find it more economical and convenient than the usual system of growing in rows. Stretch a line across the piece of ground to be sown and mark out centres 6 feet apart, and from these centres with a piece of string draw out circles 4 feet in dia-

meter, and you have the position for the seed Beans with a space of 2 feet between the circles. A circular drill may be drawn or the Beans dibbled in. For training, use rods about 10 feet in length, and with a stout piece of tarred string draw all together about two-thirds of their height by twisting the string round each rod and drawing lightly together cone shape. I should have said that before placing the rods in position a barrowload or more of half-rotten manure should be spread over the surface within the circle, which will be found of great assistance to the Beans when podding heavily, and later they should be similarly well mulched outside each of the circles. By this method of culture more Beans can be produced from a given space than in ordinary rows. I calculate one row of circles will produce the amount of three ordinary grown rows on half the space required for the latter.—C. H. D.

**Early Racehorse Potato.**—"J. C.'s" note on the Kingleader Potato suggests the inquiry if he or any of your readers knows the old Racehorse. I picked up a fine sample of it the other day, and the old labourer who had grown it for years assured me that under a common glass light he had often planted the Racehorse and eaten it in two months, and easily in ten weeks in front of a south or west wall, barring accidents from frosts. Some growers also know the Victor as the Six Weeks Potato, though I confess I have not been able to have young edible Potatoes in quantity so early from that very precocious variety; not even from greened sets boldly started before planting either under glass or in front of a south wall. I fancy, too, the yellow-fleshed Victor is the better kind. The Victor's reputation for earliness and quality is well established, but still one hears complaints of almost all favourite Potatoes being capricious as to soil and other local environments.—D. T. F.

## ORCHARD AND FRUIT GARDEN.

### RASPBERRIES.

RASPBERRIES will thrive and bear fruit in almost any kind of soil that is well manured; but the finest fruit is produced by plants growing in a deep, rich loam. Raspberries produce a thick mass of fibres near the surface, and therefore are very susceptible to drought, which causes the fruit to come small and shrivelled. Before a new plantation is made, the ground should be trenched two good spits deep, or, what is better, 2½ feet. This must, however, in some measure depend on the character of the sub-soil, as if it be of an inferior quality it will not be advisable to bring much of it to the surface. When trenching, plenty of manure or garden refuse should be worked into the ground. The best time for planting is as soon as the canes have shed their leaves. The mode of planting must, in some measure, be regulated by the form in which the canes are intended to be trained. Where stakes are available, the simplest plan is to tie the bearing canes to them, taking care that they are securely fixed in the soil. The stakes should stand out of the soil about 4½ feet, and to each of them should be tied, when the plants have become established, five or six of the strongest and best placed canes from each stool after the fruiting canes of the previous season have been removed. Assuming that this plan of training is adopted, they should be planted in lines not less than 5 feet apart, and the distance asunder in the line should be the same, or not less than 4 feet. They will not throw up very strong growths the first year, but if the fruit be sacrificed and the canes cut to within 1 foot of the ground, they will throw up much stronger canes the following season. Another mode of training is called the hedge system.

It consists in placing strong posts at each end of the row, connecting these with galvanised wires, strained through intervening iron standards. Thus a trellis is formed on which the canes are trained, and, if properly fixed, a plantation of Raspberries thus treated will last for years. Where this system is adopted the canes should be planted about 1 foot apart, and the shoots should be trained a little diagonally. Some growers dispense wholly with supports; they merely place the canes in bundles and unite the tops from each pair of stools, thus forming a series of arches on which the fruit is borne. This is, however, a plan which cannot be recommended. After planting, surface-dress with decayed manure. During the summer the ground must be kept clear of weeds and the soil occasionally loosened with the Dutch hoe. When the plants have become established and the young canes in the growing season have made about a foot of new wood, all useless suckers should be pulled away in order to admit light and air to such canes as are selected to remain. When the fruit is gathered the canes that have borne it should be at once cut out, so as to give increased space to those intended to bear next year's crop, and as soon as the leaves have

*Raspberry Baumforth's Seedling.*

fallen the latter should be thinned and regulated. After regulating the canes, some recommend that the ground be dug and a quantity of manure worked in about the roots, but it is questionable whether such practice is not a mistake. A better plan is to loosen the surface with a steel fork, and then to mulch with 2 inches or 3 inches of decayed manure, which will protect the surface roots from frost in winter and drought in summer. Of varieties, the best are Fastolf, Baumforth's Seedling (here figured), Scupper Fidelis, Belle de Fontenay, Hornet, and Superlative. T.

**Raspberries and frost.**—Mr. Prinsep's note on the above (p. 329) is instructive, as it clearly proves the importance of plenty of room for the canes. Setting aside the deaths which invariably occur in very sharp winters amongst plantations unduly crowded with canes, I contend that the yield is less and the quality of the fruit inferior to that from canes grown on the post-and-wire system. These receive a maximum amount of sun and air, and become stout, vigorous, and thoroughly ripened; therefore able to stand almost any amount of frost. A mistake which we may fall into is allowing all the new canes to grow until the autumn before reducing their numbers. They should be freely thinned as soon as it can be dis-

tinguished which are the best, and the old bearing canes cut away immediately the crop of fruit is gathered. If these details were attended to Raspberry growing would be found much more profitable. I think some of the older varieties, such as Fastolf and Red Antwerp, are hardier and more frost-proof than newer kinds, although some of the latter certainly have larger fruit.—C. N.

### THE APRICOT.

THOSE who have only a fair crop of Apricots this season may think themselves fortunate, as in the majority of gardens they will be very scarce. Hereabouts many gardeners did not protect their trees, the few puny blossoms not being worth the trouble. As soon as the buds commenced to enlarge it could be seen that they would not only be few in number, but much weaker than usual. This condition is attributed by some to the heavy crops the trees have borne the last few years, but I think this idea is erroneous, as trees which have been regularly and freely thinned of their fruit and nourished at the roots were as thin of bloom this spring as those which had been unfairly cropped and ill nourished. My own opinion is that last autumn the wood of Apricot trees, lacking heat, did not become sufficiently ripened, and that in consequence the bloom buds were unable to withstand the terrible frost of February even though only in their embryo state.

It will be remembered that the weather was extremely mild up to the beginning of January, and that the wood of fruit trees generally was then in a soft and sappy condition, so much so, that the wonder to me is that Pears, Apples and Plums are showing such an abundance of bloom with the minimum amount of sunshine that characterises our summers and our too frequently damp cold autumns. Disbudding is carried out in very few gardens, and the trees become such a thicket, that light and heat are much impeded, and stout, well-ripened wood becomes next to impossible, the evil becoming more apparent after a sharp winter. I think the trees need disbudding early, as in the case of Peaches and Nectarines, the growths which spring from old spurs being freely thinned out. Overcropping the trees is a great evil, and must be paid for sooner or later. The branch-withering or paralysis is a great drawback to Apricot culture now-a-days. Time was when this malady was almost unknown. Another common cause of failure, especially with amateurs, is planting in too rich soil. Farmyard manure should never be added to the border, but applied as a surface mulch to established trees bearing full crops. A warm, somewhat sandy soil suits Apricots well, the same being made very firm, and plenty of lime scraps added. In dry summers lack of water causes premature exhaustion and branch-withering, especially with trees carrying heavy crops. Of late years the demand for young Apricot trees has been great, so many amateurs having planted them. This has induced nurserymen to give them a rich soil in order to grow them into a saleable size as soon as possible, but trees grown on poorer land and having thin, matured wood are infinitely better. In a gentleman's garden near here the Apricot thrives in an exceptional manner. The trees occupy a west wall, produce wood of moderate thickness, and almost annually yield immense crops. When the fruit is swelling the roots receive

copious supplies of liquid, poured over a heavy mulching. The gardener has what may be termed a preparatory wall, from which trees are occasionally removed to fill spaces on the Apricot wall proper. The border is of a sandy nature, extremely shallow, and by reason of being an every-day route for foot-passegers, becomes as hard as a turnpike road. The surface is never interfered with except when a tree is removed, when it is found that permeating this hard and limited area is a mass of wiry, fibrous roots which have produced a corresponding top growth. When any of these are removed into the permanent border—which, by the way, resembles the one above referred to—they retain the good constitution they have acquired and go on from year to year. From this I gather that loose borders should be avoided in the cultivation of this fruit, and that the admixture of animal manure lays the trees open to the attacks of those disorders which usually follow a sappy and immature condition of the wood. For those who are not favoured with the best of climates I can confidently recommend Hems-kirk, as being hardy, free-bearing and less liable to die off than Moorpark.

Newark, Notts.

J. CRAWFORD.

#### GRAPE MADRESFIELD COURT.

EVERY season the question as to the why and wherefore this grand Grape should crack so badly under treatment that does not similarly affect say, the Black Hamburgh, invariably crops up, and is likely to do so as long as it retains its popularity. This cracking is a great drawback to the variety, its one great fault in fact, and how to prevent it is the difficulty. According to my experience the berries are far more liable to crack in some localities and even in some positions in a garden than in others. The treatment, therefore, that answers well in one case may be altogether wrong in others, and what we have to do is to study local circumstances and proceed accordingly. I have tried the plan of keeping the borders constantly moist and the roots liberally fed during the ripening period, but that alone did not stop the wholesale cracking of the berries on the first dull muggy day we had, after colouring had well commenced. Keeping the borders very dry, or to the extent of causing adjoining Vines to flag from want of water was no remedy at all, but on the contrary the check thus given to the enlargement of the berries predisposed them to cracking directly either the borders were watered or the atmosphere of the house became highly charged with moisture. It appears to me that the skins of the berries are either peculiarly tender, or they are more porous than those of most other Grapes, as I have not the slightest doubt now that it is owing to the excess of moisture passing through the skins and uniting with that already there that the expansion and consequent splitting take place. Directly I admitted the correctness of this theory, that is to say the principle of osmosis, my troubles as regards the cracking of Madresfield were practically at an end. Keep up a good circulation of warm dry air and there will be no splitting of berries. In low-lying positions and where the sub-soil of the district generally is of a retentive clayey nature, there is far more moisture in the atmosphere than is the case on higher ground and where there is a gravel or chalky sub-soil. If I am correct in these conclusions, then the Madresfield Court is not a good Grape for low-lying positions, for mixed vineries, or for unheated structures generally. There are times when fire-heat is

absolutely needed in order to keep up the necessary free circulation of dry air. Free ventilation alone will not always prevent moisture from accumulating on the berries, and once they are dewed over it is a case of good-bye to the greater portion of the crop. It is also of importance that low night temperatures be avoided while the berries are stoning, and later on while yet green, as these may lead to wholesale scalding. Warmth in the hot-water pipes, with a little top air on all night, is the best preventive of scalding; and warmth in the hot-water pipes, with both front and top ventilators open a little way all night long and somewhat widely in the daytime, is the surest preventive of cracking. A sudden rise in the temperature—owing to a change from dull, cloudy weather to an outburst of sunshine—must be guarded against.

When the Madresfield Court has a house wholly given up to it there is really no excuse to be urged by those in charge for the loss of many berries by cracking, but in mixed houses the case is different. An extra free circulation of air admitted while yet the berries of any varieties of Grape are swelling fast tends to check this progress, the largest berries being had with the aid of a more or less moist atmosphere, and which does not cause all alike to crack badly. That is one reason why I gave it as my opinion that Madresfield Court is not suitable, as a rule, for mixed houses. Even if it can be prevented from cracking in a fairly moist atmosphere the extra gain in size of berries does not often compensate for the loss of colour. How often are those very fine berries coloured right up to the foot-stalks? Very rarely, if ever. Madresfield Court, as most often seen, is nearly green at and about the foot-stalks of the berries, and is certain to be so unless abundance of air is given almost constantly from the time colouring commences. As it happens, what is a remedy for cracking is also favourable to perfect colouring, and those who would have this noble Grape at its best and cannot afford to give a house wholly up to it, will do well to plant it at the outside end of a compartment, so as to be able to give it air very freely without subjecting the other varieties to more of it than desirable. With me it never failed to colour well, and the secret of it lay in the fact that several squares of glass were taken out at the ends and half-inch mesh galvanised wire netting substituted. Some of these openings were made exactly opposite bunches, and there was no mistake about these being the most perfectly coloured and carrying the best bloom. There was no green to be seen in the berries after they were once ripe, and if they were smaller than desirable they did not present a somewhat polished appearance, but, on the contrary, carried a thick bloom.

W. I.

**Apricots.**—Apricots are not fruiting in our garden (South Bucks) this year. The bloom was somewhat thin and the trees have not set more than half a crop. Last year's crop was a heavy one; the trees also made good and healthy growth, but probably it was not sufficiently ripened to produce a full complement of fruit buds and blossom this season, although other wall trees—Plums, Peaches and Nectarines—in the same garden give promise of abundant crops.—C.

**Strawberry Noble.**—I very much question if any variety of Strawberry has given a better return than Noble. I quite agree with "E. M." (p. 329) as to its cropping qualities and its value when lifted. The value of Noble is its robust habit. In forcing as "E. M." advises it is necessary to do it slowly to get the best results, as if at all hurried Noble fails to set its flowers, but if given time it answers admirably. A large grower near me allows his plants to remain out till the

end of February after layering as described (p. 329), lifting them carefully, potting up and standing under a north wall for a month. He then forces in a cool house and supplies the market just at a season the forced fruits are over, getting a very good return and at a small amount of labour. I note it is still much employed by hybridisers, its bold habit and free growth making it valuable in this respect.—W.

#### FRUIT PROSPECTS IN MAY.

A LENGTHY run through East Anglia and some other counties enables me to give a pleasing account of our fruit trees and bushes in bloom. The season within the last few weeks has advanced by leaps and bounds. Little more than a month ago most people were accepting a late season as a matter of course, but April showers and other causes have already put the growth and flowers of the year abreast of the calendar. So early as the first week in May most of the fruit trees were already out of blossom, and the glorious ten days of May sunshine have done much to set the fruit of Plums, Pears, Cherries, as well as to foster Peaches, Nectarines, and Apricots on walls to abnormal size and earliness. The Apple blossom, now in full glory of purple and white, has been the crowning glory of May. Next to the Apple blooms, Cherries have been the most profuse in flower, and all, with the exception of May Dukes, seem setting and swelling fairly well. I find that the May Dukes have neither been blighted nor frozen, but picked off. The birds prefer these in bloom to Black or White Hearts or any other Cherries. In not a few localities, too, Cherries this season came into bloom rather before their time. The order of blooming may generally be stated thus: Black Thorns or Sloes, Damsons, Gages, and other Plums, Cherries, Pears, Apples. This season Cherries were ahead of Damsons and Gages.

Plums of all sorts also showed some striking peculiarities in blooming this year. As a rule the blossom comes well abreast of the foliage. The bloom is so profuse and plentiful, that there is nothing else, no green visible. Those who watched for this whitening over of their Plum gardens and orchards this year were disappointed. Throughout the spring so far their trees have been green, not white. This arose, however, less from the paucity of flowers than the time of blossoming, for this season the growths of Plums were a week or more ahead of the blooms. Hence in most of the orchards I have seen there are Plums enough for an average yield. The brilliant sunshine during the first fortnight of May has also made short work of the setting of most of our fruit crops. The longer and wider my experience among fruits, the deeper my conviction that a rapid set is the most favourable to the free swelling and perfect finish of our crops. With a sunny May up to the 15th or 20th there will be a good set of Apples throughout the southern, midland and eastern counties, and seldom has there been a more magnificent blossoming, never a finer, cleaner, earlier growth of foliage.

D. T. F.

**Thinning Grapes for exhibition.**—Although Grape-thinning always demands great care, yet when the bunches are intended for exhibition more precision is requisite. We often see the shoulders of bunches at shows in a loose, irregular condition, entirely spoiling the general appearance of the bunches. In many instances too many berries are taken out from the upper portion of the shoulders, causing them to fall about when placed on the board. As a rule very few berries should be removed from the tops of the shoulders, the berries beneath will push them up as swelling goes on. More shoulder-thinning is needed with some free-setting varieties, but even with these discretion is necessary if exhibiting is intended.—J. C.

**Apple King of the Pippins.**—This well deserves the note at p. 310 by "W. G. C." and the

praise he bestows upon it. I am sure, taking everything into consideration, it may be classed as the best all-round dessert variety grown. "W. G. C." rightly places it second to Cox's Orange and Ribston. I have never failed to fruit the King in this part of the country, and in the north it was the most reliable kind. In the west of England it was simply grand; the tree was not only most prolific, but the fruit was of very good quality. The illustration at p. 310 hardly does it justice when grown in a good loam. Those who have not included this variety in their collections certainly lose a quantity of good fruit, as the King often fruits when all others fail. Few varieties are more reliable and the fruit keeps a long time.—G. WYTHES, *Syon House*.

## TREES AND SHRUBS.

### THE WISTARIA.

THE Wistaria is again flowering with its usual profusion, not having suffered in the slightest degree from the extreme cold, which accentuates its worth as a garden climber. There is plenty of good specimens about, but it is a pity that people do not plant it even more freely and in varied ways as suggested above. The exceeding beauty of old specimens is surely worth striving after, and although they represent many years of growth, it is a fast growing plant, and we have not long to wait before getting some flowers in return if we plant it under favourable conditions in free light soil. In exposed places the flowers of Wistaria are sometimes injured before expansion by late spring frosts, but in favourable years they escape, and then the Wistarias are seen to the best advantage, as, in addition to the blooms, the freshly expanded foliage is thus, in common with that of all outdoor trees and shrubs, very fine. The Wistaria is generally treated as a wall plant, but it has also a beautiful and picturesque appearance when so situated that its vigorous branches can ramble into the head of a neighbouring tree. If planted with this intention, a mistake too often made should be avoided—viz., that of planting the climber too closely to the tree which is intended as its support, for if planted close to the trunk of an established specimen the new-comer is simply starved to death. The Wistarias, too, are well suited for arbours, and a large specimen just supported by a framework of some kind forms a beautiful object on a lawn. Though one seldom meets with any Wistaria except the Chinese form, there are several others, one or two of which are perhaps worthy of being planted to a greater extent than at present, but as they are of far more recent introduction than the one above mentioned, the plants are small, and, consequently, cannot be compared with those of the older species. A promising variety is the white-flowered form of the Chinese Wistaria (*W. sinensis alba*), which appears to be a counterpart of the type, except that the flowers are pure white. A very pretty effect might be produced by planting this and the ordinary form in such close proximity to each other that as they grew up the branches of the two would intertwine one with the other.

**Cerasus Mahaleb.**—The wood of this is much sought after for cabinet work, as it is very hard and takes a good polish, and in addition to this it

has an agreeable perfume. Apart from any of these considerations, however, it is well worth planting as an ornamental tree, for it forms a rounded head whose slender shoots are clothed with ovate leaves of a pleasing shade of rather pale green. The flowers, which are pure white, are small and borne in rounded racemes. They are so numerous that a good example is when at its best quite a mass of white, and this is, as a rule, towards the end of April or early in May. Though the typical kind is remarkable for its graceful style of growth, there is a variety—pendula—which is much more so. In this all the minor shoots have quite a drooping tendency. It is not, of course, as weeping as some other trees, but the shoots are just sufficiently drooping to impart a grace and elegance to the entire tree. Though it will attain the dimensions of a tree, *Cerasus Mahaleb* will often form a densely-branched shrub-like specimen. One great point in favour of it is that it will succeed in dry, sandy or stony soils better than most subjects, and this, combined with its graceful habit and profusion of bloom, should render it worthy of more notice than has hitherto been bestowed upon it. The

as a rule retains its colour throughout the season, unless red spider attacks the foliage, which sometimes happens during a hot summer, or very fierce sunshine is apt to scorch the leaves. The pale pinkish flowers of this variety are inferior to those of many other garden forms. *Spiræa opulifolia aurea* is less in stature than the normal form, while it is one of those shrubs that lose a good deal of their colouring as the season advances. It is wonderfully pretty quite early in the spring, just as the young leaves are unfolding. Then the warm brown branches are studded with golden tufts of partially expanded foliage, which at a little distance look like yellow blossoms. The golden-leaved form of the Mock Orange (*Philadelphus*) is a pretty shrub, less rich in colour, it is true, than some others, but still well worth planting: it does not attain the dimensions of the common kind. *Cornus Spathi*, which has within the last three or four years attracted more attention than any other golden-leaved shrub, is certainly one of the best of that tint that we have in our gardens. The leaves, which when expanding are tinged with bronze, become of a clear golden hue, except an irregular-shaped blotch of

*Wistaria over a balcony.*

**Mahaleb Cherry** is indigenous to the greater part of Europe, particularly in the mountainous parts of France and Switzerland, and in a wild state it varies, according to the position in which it occurs, from a tree to quite a bush. According to Loudon, it was introduced into this country in 1714. By the Kew authorities the generic name of *Cerasus* has been superseded by that of *Prunus*, so it must now be referred to this genus.—T.

### GOLDEN-LEAVED SHRUBS.

WHILE several of our golden-leaved shrubs are very beautiful just now, they do not all retain the yellow tint throughout the entire season. A particular instance of this is to be found in the dwarf-growing *Ribes alpinum pumilum aureum*, the leaves of which when first expanded are of a beautiful golden tint, but by midsummer a great deal of its characteristic colouring has gone and the leaves soon become quite green. The golden-leaved Elder, on the other hand, is at its best during the hot days of July and August, especially if it is in a position fully exposed to the sun and in not too rich a soil. *Weigela Looysmani aurea*

green in the centre. *Ligustrum ovalifolium elegantissimum* is a beautiful golden Privet, whose style of marking is in much the same way as that of the *Cornus* just mentioned. The Privet is, however, almost if not quite evergreen, so that its season of beauty is spread over a longer period than that of the other. It is sometimes used for winter bedding, and if the weather is mild it is very effective. *Ptelea trifoliata aurea* is a variety of this distinct shrub with golden foliage, and there is also a form of the Hazel (*Corylus Avellana*) of the same tint. Several of our trees have varieties remarkable for their golden foliage, notably an Oak—*Concordia*, rich in colour; a variety of the False Acacia—*aurea*, of a pale greenish yellow; the Golden Alder, a grand subject for the water-side; two or three varieties of our native Elm, a form of the Laburnum, golden both in flower and leaf; and *Catalpa aurea*, whose leaves are larger than those of any other shrub or tree mentioned above. H. P.

**Kalmia glauca.**—Few, I think, will be found to agree with Mr. Webster in his book, "Hardy

Ornamental Flowering Trees and Shrubs," in his opinion of this *Kalmia*, for he says, "This, which has lilac-purple flowers produced in early spring, is not a very desirable species, being rather straggling in growth and with few flowers." That is certainly not the estimate in which it is held by many, for it is at all events regarded by some as among the most desirable of low-growing shrubs that bloom as a rule in the early part of May. The general habit of *Kalmia glauca* is to form a little compact shrub from 1 foot to 2 feet in height, clothed with neat foliage, glaucous on the under sides, while the pretty purplish pink blossoms are borne in such profusion that when at its best the entire plant is quite a mass of bloom. A bed planted with this *Kalmia* forms a remarkably bright and effective spring feature, and as a succession to it we have *Kalmia angustifolia*, a rather upright-growing species that is as a rule under a couple of feet in height. The flowers of this are of a deeper tint than those of the preceding, while there is a variety—*rubra*—darker still. The last to bloom is the larger growing Mountain Laurel (*Kalmia latifolia*), which is well worthy of association with the numerous beautiful garden varieties of *Rhododendrons*. All of the *Kalmias* can be forced into bloom, but they must be brought on gently, as if too much heat is used the blossoms fail to open in a satisfactory manner.—T.

#### SHORT NOTES.—TREES AND SHRUBS.

**Siberian Crab** (*Pyrus prunifolia*).—By far the finest object in flower in the garden here at the present time is a tree 30 feet high, having a branch-spread of 40 feet, of the common Siberian Crab. The tree is standing upon Grass, its lower branches sweeping the turf. Before the blooms are fully developed the delicately pink-tinted buds present a pretty sight.—E. M.

**Kerria japonica fl.-pl.**—Never have I seen this deciduous shrub flowering in such profusion as at the present time. In this neighbourhood there is hardly a cottage garden but can boast of a plant or two. In some instances it is planted at the foot of a south wall. The warmth of such a sunny position appears to suit its requirements to a nicety. Trained loosely to the wall it produces a charming effect when smothered with its rosette-like blossoms of a rich orange colour.—E. M., *Bishop's Waltham*.

#### SOCIETIES AND EXHIBITIONS.

##### ROYAL HORTICULTURAL SOCIETY TEMPLE SHOW.

MAY 21, 22, 23.

ANOTHER Temple show, to use the definition mostly expressed, has been held, and it has proved to be fully equal to its predecessors, if not in some respects the finest yet seen. The arrangement was varied, and that with decidedly better convenience than at previous shows. The first three marquees usually stood on a lower level and on grass, making it somewhat unpleasant should the weather prove unfavourable. On this occasion they were ranged along the broad gravel walk on a higher plateau nearer the Thames Embankment, thus affording quite a dry promenade. The overflow tent for Orchids and the choicer exotics was placed parallel with the foregoing in about the same position as previously, whilst the monster marquee, now a proverbial figure in these gatherings, was at right angles with it and in its usual spot. By this arrangement of the tents the space at disposal for an outside promenade was much extended, thus creating another improvement; whilst yet another was evident in the connecting canvas awnings between one tent and another, so that the entire show could be inspected without going outside should the weather prove to be wet. The entire arrangement reflected the greatest credit on the executive of the R.H.S., whose marquees, it should be stated, could easily have been filled,

entries being refused, reduced and restricted simply from want of space whereon to stage them. Considering that it is not an ordinary exhibition where prizes are offered and won, its success year by year speaks well for the enthusiasm evinced in horticulture around and beyond the metropolis. A few well-known exhibitors were conspicuous by their absence, but this was not felt in such an extensive display as one might expect.

The first marquee on entering the grounds was chiefly devoted to cut flowers and floral decorations, the latter showing a marked advance in quantity, whilst the quality was fully maintained. Notable here were the unique displays of Messrs. Perkins and Son and those of Mr. Chard, the former of most *riche* character, the latter somewhat light and airy. Messrs. B. S. Williams and Son and other fresh exhibitors entered in this section for the first time with most praiseworthy produce. Other exhibits in this tent comprised choice selections of vegetables, notably salading from Messrs. J. Carter and Co., excellent vegetables from Mr. Wythes and other well known growers, fruit from the same and other sources, also the florists' Tulips in the competitive classes, which were shown well. In the second tent were to be found several specially good exhibits, most prominent amongst which was the comprehensive one from Messrs. Sutton and Sons, who have never before staged so fine an exhibit demonstrative of practical gardening. Of very special note here were the several kinds of early Peas in pots, finely grown, also of Tomatoes heavily fruited, with other fine produce. Carnations, Cannas, cut flowers and Ferns from other sources filled this tent. The third marquee in this line comprised a very prominent exhibit of Filmy and other Ferns, also of alpine plants on rockwork, a very instructive and suggestive method of staging. Another grand display in this tent was that of Messrs. Veitch and Sons, who staged a fine assortment of *Streptocarpis*, including the new *S. gratus* hybrids, which are a coming race in this genus. With these were their new hybrid Cacti, Ferns of the best kinds and *Gloxinias*, other exhibits comprising cut flowers in quantity. Next in order came another Orchid tent, itself far beyond the average of such erections; this was filled to overflowing with choice collections of Orchids from such well-known exhibitors, growers, and importers as Messrs. H. Low and Co., Messrs. Charlesworth and Co., and Mr. Jas. Cypher, all of whom on this occasion may fairly be said to have excelled themselves. Smaller collections came from Messrs. W. L. Lewis and Co., Southgate, and others. *Acers* in choice vars. came from Messrs. Fromow, a pretty exhibit. Roses were here staged by Mr. F. Cant and Messrs. Jackman, also *Cilicolarias* by Messrs. James and Son. This tent also contained a most noteworthy exhibit in the new and rare plants staged by Messrs. F. Sander and Co.: prominent amongst which were new *Dracenas*, one quite a unique species, viz., *D. Godseffiana*; also of dwarf growing, richly coloured variegated *Begonias*, and of *Heliconias* resplendent in colouring. Grandly grown *Sarracenias* were included here also. *Pelargoniums* from Slough and elsewhere in a blaze of bloom helped to enliven one end, as did that splendid exhibit of cultural skill to be seen in the immense bank of *Leschenaultia biloba* major in perfect condition and profusion of flower from the now well-known growers of this fine old hard-wooded plant, Messrs. W. Balchin and Sons, Hassocks, Sussex, with which were included equally good examples of *Boronia serrulata*. *Begonias*, too, of the tuberous section were staged in this tent, making a magnificent display, both Messrs. H. Cannell and Sons and Mr. Thos. S. Ware contributing large and splendid groups, high class culture being evinced in each instance. On entering the large marquee the first group to attract notice is a superb display of Malmaison Carnations from Mr. Jennings, gardener to Mr. Leopold de Rothschild, who has previously shown these in very fine condition, but never better than on this occasion. Orchids and Roses were the two

prominent features in this tent, the former fully maintaining their position, whilst the latter were never seen in finer condition before, those noted growers Mr. Chas. Turner, Messrs. W. Paul and Son, and Messrs. Paul and Son vying with each other in their respective groups. Most noteworthy of all the Roses shown were the superbly-flowered plants of *Crimson Rambler* from Slough, staged in diversified forms of training. Splendid groups of hardy-flowering trees and shrubs (a unique display) and of *Caladiums* came from Messrs. J. Veitch and Sons, another of the latter, also excellent, being contributed by Messrs. Peed and Son. Clematises from Messrs. R. Smith and Co., Worcester, added to the display in this tent, as did the two suggestive decorative groups of Mr. Icton and Messrs. Wills and Segar, which competitive exhibitors would do well to imitate.

#### ORCHIDS.

Sir Trevor Lawrence, as usual, had a magnificent exhibit, in which there was a great variety of choice things. *Masdevallias* were in strong force, comprising *M. Harryana Denisoniana*, very rich in colour; *M. Mundyana*, of a deep orange shade, very distinct; *M. Veitchiana*, extra fine; *M. Gelenium*, of dwarf growth; and *M. Harryana miniata*, an intensely deep scarlet. Of *Odontoglots* there were also several choice varieties, particularly of *O. crispum* and *O. Pescatorei*. *O. vexillarium* was also included. A most noteworthy exhibit in this group was a very fine mass of *Anacochilus* in most luxuriant health. Other exhibits in this group comprised *Cattleya Mossie* and *C. Mendeli*, both in good character. *C. Schilleriana* is rarely seen so healthy. *Laelia purpurata* was represented by some grand varieties. Of *Cypripediums* there was a grand example of *C. Stonei platyanium* bearing two spikes each with as many blooms of extra size and finely coloured, the petals broad and well marked, with both the upper and lower sepals of equally fine proportions; this plant was a centre of attraction. Other good varieties of *Cypripediums* included *C. calanthum* showing its affinity to *C. Lowi*; *C. Hookeri voluteatum*, extra good; *C. barbatum*; *C. Lawrenceanum*; *C. Lawrencei*, specially fine; *C. superciliale* and *C. Swannianum superbum*. *Dendrobium Bensoni*, with two dense racemes, was very fine; *Vanda suavis*, a dwarf plant with a good spike; *Oncidium Rogersi*, with two dense spikes; *Epidendrum Stamfordianum*, a grand specimen in the finest possible condition, covered with dense spikes of bloom; *Dendrobium revolutum*, a small species of singular growth; *Oncidium macranthum*, dark in colour; *Vanda tricolor*, with four spikes; and *Epidendrum radicans*, well-flowered, were also shown. A well-bloomed *Calanthe veratrifolia* was also included, as well as *Microstylis macrochila*, a singular Orchid of dwarf growth.

Baron Schroder, The Dell, Egham, occupied his usual post next to Sir Trevor Lawrence on and at one end of the centre stage in the large marquee, his collection being fully up to the standard of past years, the whole group forming a wealth of floral beauty. Of specimen examples there was a grand mass of *Ada aurantiaca*, finer by far than it has been previously seen, being one mass of flower-spikes. Of *Cattleya Skinneri* there was also a fine specimen, with nine dense spikes of richly coloured flowers. *Odontoglossums* were in strong force, *O. crispum apium* (the variety beyond compare) being present, the stout spikes carrying fourteen flowers and buds of large proportions. *O. excellens* bore a stout, dense spike, the flowers richly coloured. *O. Wilckeanum giganteum* bore a gigantic spike of unusually large flowers, the ground colour creamy white, the dark chocolate spots being in marked contrast. The flowers of this *Odontoglot* are fully 5 inches across. *O. crispum xanthotes*, the pure white variety, with golden spots, a charming form; *O. crispum* in choice varieties; *O. luteo-purpureum*, very dark in colour; *O. vexillarium*, a specially rich form in point of colour; and *O. nebulosum*, a most beautiful variety, were also shown. *Cypripedium levigatum Rebelini*, a very choice form, had four

spikes; *Masdevallia Veitchiana grandiflora* was shown extremely fine, the flowers of unusual size and colour; *Laelia purpurata* was present in very choice varieties, notably *L. purpurata Schrödera deliata*, a lovely form. Another gem was to be seen in *Laelia Cattleya Hippolyte* of deep colouring. Amongst other choice things were *Cypripedium Sanderianum*, with long tail like appendages; and a grand plant of *Masdevallia nycteryna*, one of the most beautiful of the dwarf varieties with about three hundred blossoms.

Mr. S. Ellis, Hazelbourne, Dorking, staged a splendidly grown group of *Odontoglossum crispum* in the choicest vars., notably the light forms, which with the following constituted a most attractive exhibit: *O. Pescatorei* in beautiful condition, *O. citrosimum*, *O. luteo-purpureum*, a fine spike; *O. ramosissimum*, a charming small variety, very elegant; *O. cordatum*, *O. Coradinei*, a fine plant with five spikes; and *O. polyanthum*, extremely fine, a well marked form, the group as a whole looking most attractive.

From Earl Percy's collection at Syon House Mr. Wythes staged a thoroughly representative group of the best Orchids now in season, containing a great number of varieties and fewer duplicates than some exhibits. *Vanda teres* was here shown well, the plants extremely healthy. *Cymbidium Lowi* was in its best forms, several spikes carrying over twenty flowers, one form being specially good, with the crimson of the lip of a deep shade. *Laelia purpurata* was present in the best varieties, the flowers of large size, one white variety being extra fine. *Cattleya Mossiae* was here shown well; so also was *C. Mendeli*, as well as *C. Skinneri*. *Dendrobium thysiflorum* in this group was specially good, bearing long dense racemes. *Odontoglossum citrosimum*, *O. vexillarium*, *O. cordatum*, and *Dendrobium suavisimum* were all good.

From Mr. S. Cooke came a small exhibit which comprised capital forms of *Odontoglossum Alexandrie* (*crispum*), *O. Ruckerianum*, *O. nebulosum*, *O. Lindleyanum maculatum*, *O. Coradinei*, *O. cordatum*, and *O. Pescatorei*.

Messrs. F. Sander and Co. as usual staged a magnificent group, occupying a greater space with Orchids alone than any other exhibitor. Of *Oncidium sphaecelatum* there was a grand specimen, forming a fine feature. *Odontoglossum vexillarium* was staged in large numbers, both light and dark forms, the plants in the best of health. Varieties of *Microstylis*, in several very singular species, were shown in a pan by themselves. *Dendrobium Auguste Victoriae*, a tall-growing species, with long spikes of light coloured flowers, a beautiful variety; *Laelia Cattleya Phoebe*, a charming hybrid in the way of *L. C. Hippolyte*, with the sepals and petals of a lighter shade of orange, a choice plant; *Odontoglossum crispum* *Duchess of York*, a pure white form, with pale gold markings on the lip; *Cattleya Lawrenceana*, of specially deep tint; *Odontoglossum prionopetalum album*, a distinct form, with the ground colour pure white; *Cattleya Mendeli*, specially fine, the colouring of the lip an intensely deep crimson-purple, a very fine form; and *Cymbidium Lowianum*, an immense specimen, were also shown. *Cattleya Skinneri*, well-flowered; *Aerides expansum*, a very healthy plant with a long spike of flowers; *Brassavola Digbyana*, rarely seen, singularly beautiful; *Cattleya Mossiae Wageneri*, a beautiful example; *Cypripedium Lawrenceanum*, with a number of fine blooms; *Odontoglossum polyanthum*, bearing two stout spikes, very handsome; *Laelia purpurata alba*, with large, pure white flowers, the lip deep purple; *Maxillaria Sanderiana*, a sturdy plant, were also included with several other choice varieties and species. *Cattleya Mossiae Prince of Wales*, a specially fine form with the lip of unusual breadth; *L. purpurata Princess of Wales*, a distinctly beautiful white form; *Spathoglottis aurea*, very bright; *Sobralia Veitchi* (*St. Albans* variety), *Phaius Owenianus*, a dwarf hybrid of rich colour; *Oncidium phymatocilium*, a beautiful and very light species; and *Cattleya dolosa*, a charming species with soft pink sepals and petals, a gem, showing a considerable varia-

tion in colouring, were here to be seen. Of *Cypripedium Chamberlainianum* there was a grand mass, bearing a dozen or more flowers, and of *Cattleya Mossiae* a fine specimen was staged.

Mr. J. G. Fowler, Glebelands, Woodford, had a choice group, in the centre of which was a fine example of *Epidendrum Wallisi*, to which a cultural commendation was awarded. The tops of the bulbs were wreathed in blossom, the rich golden shade of which was particularly striking; *Cattleyas* were a strong feature in this group. *Cypripedium Chamberlainianum* was also specially good. *Phalanopsis amabilis* was here shown well. *Odontoglossum crispum* was staged well, the plants very vigorous and the spikes correspondingly so, whilst the varieties were of the best. *Dendrobium cretaceum*, not often seen, was shown here; also *Oncidium Lanceanum* of rich colour; *Odontoglossum polyanthum* and *Odontoglossum cordatum* were both in good order; whilst of *Cypripedium bellatulum*, a very fine variety of dark markings was present, and of *C. Lawrenceanum* a good specimen was staged. Of quite rare forms were *Cypripedium Lawrenceanum* *Hyeanum* specially fine, the dorsal sepal being of the purest white and deep green; and *Cattleya Mossiae* (Fowler's var.), void of the purplish crimson lip, this giving place to pale gold and lilac.

Sir F. Wigan, Clare Lawn, East Sheen, had a small but *richoché* group. *Cypripedium Rothschildianum* was shown here extremely fine; so also was *C. Lawrenceanum*. *Cattleya Mendeli* was present in the choicest varieties, specially so in one or two instances. *Cattleya Mossiae Lady Wigan*, a delicately beautiful variety, stood out prominently, as did a fine plant of *Vanda snavis*, bearing an extra fine spike. *Cattleya Schilleriana* had two fine blooms, and Chamberlain's *Cypripedium* was shown well. From Mr. Wells, Bromfield, Sale, came *Cattleya Mossiae*, of rich colour and *C. hybr.* (*C. exoniensis* × *C. Mendeli*).

Messrs. B. S. Williams and Son staged a large group at the opposite end to Messrs. Sander. This comprised a fine selection, with a profusion of flowers. Here were to be seen *Oncidium concolor*, a beautiful dwarf, yellow species, well-flowered; *Odontoglossum crispum* in quantity, specially good, with long, arching spikes; *Cymbidium Lowianum*, still in good condition; *Laelia purpurata*, with fine blooms; *Ada aurantiaca*, *Dendrobium thysiflorum*; *Maxillaria Sanderiana*; *Cypripedium grande*; *Vanda suavis*, with good spikes; *Oncidium sarcodes*, in good colour and fine spikes; *Ornithocephalus grandiflorus* (the Lily of the Valley Orchid); *Calanthe veratrifolia*, with good spikes, very fresh; *Cypripedium Schrödera*, richly coloured; *Cattleya Skinneri*, good; *Odontoglossum polyanthum*; *Oncidium Marshallianum*, extra fine, a choice Orchid; *Cattleya Mossiae*, an extra fine, deeply-coloured form; *Cypripedium Chamberlainianum*, bearing large blooms; *Odontoglossum Harryanum*, here noted for the first time; *Vanda Dennisoniana*, *V. teres*, both excellent, and *Brassavola nodosa*.

Messrs. Charlesworth and Co., Heaton, Bradford, staged in the adjoining tent a large and excellent group, in which *Oncidium Marshallianum* and *O. macranthum* were unusually fine, the spikes being well flowered and the blossoms large as well as rich in colour. *Odontoglossum cirrhosum*, *O. cordatum* and *O. crispum* were all included here, the latter in quantity and good in quality; *O. vexillarium* and other varieties being also staged. *Cypripedium superciliosum* and *C. Lawrenceanum*, with several plants of *C. bellatulum*, were also to be seen. *Laelia cinnabarina* here appeared, also *Cymbidium tigrinum*, *Laelia purpurata*, large plants well-flowered; *Cymbidium Lowianum*; *Cattleya Mossiae*, with an extra fine piece of *Dendrobium thysiflorum*. *Odontoglossum crispum* in one instance was represented by a richly-marked form. *O. Halli* and other species were also noted. *Cypripedium Chamberlainianum* and *C. Rothschildianum*, the latter extra good in colour; *Oncidium concolor*, *Ornithocephalus grandiflorus*, *Odontoglossum ramosissimum* and other uncommon kinds were included here.

Messrs. H. Low and Co. staged the best group they have thus far in their long experience exhibited; this was resplendent from end to end with the choicest varieties of *Cattleya Mossiae*, a speciality of this firm, who appear to have quite a monopoly of the best forms. Some grand masses of this one of the finest of all *Cattleyas* were shown here, quite large specimens and in profuse flower. These forms of *Mossiae* were throughout notable for the breadth and colouring of the labellum, some of the darkest shades and others of the lightest. *Laelia purpurata* was specially good, being present in great variety of colour. *Cypripedium caudatum Wallisi*, the light form of the type, was also included. Of *Cattleya Reineckiana superbissima* there was a good example. *Laelia purpurata Enfieldensis* had extra large and deeply coloured blooms.

Mr. Jas. Cypher, Cheltenham, had a grand group, in which the finest possible culture and choice varieties were combined in a marked degree. *Laelia purpurata*, in its finest possible varieties, was here a most remarkable feature, being the very deeply-coloured forms, particularly good, the purple of the labellum in several instances of the deepest possible shade. Other forms with the purest white in the sepals and petals were to be noted, all being in grand health. *Cattleya Mossiae* and *C. Mendeli*, with *C. Schilleriana*, were also excellent. *Odontoglossum cordatum* of deep colour; *O. crispum*, *O. triumphans*, and *O. Halli* were also staged well, as also was *O. Reichenheimi*, a distinct species. *Dendrobium Falconeri* appeared here, the only instance in the show, two good plants being staged, both freely flowered. *Dendrobium moschatum*, not often seen in any show, was found here with three good spikes. *Epidendrum radicans*, extra fine and profusely flowered; *Phalanopsis speciosa*, a good spike; *Dendrobium Dearei*; *Oncidium concolor*; *Sophronitis grandiflora*, extra good; *Saccolabium ampullaceum*; and *Odontoglossum maculatum* were staged. Of *Oncidium varicosum* there was a very fine plant bearing a strong spike. *Cypripedium grande atratum*, of extra deep colour, a splendid form of this hybrid, was shown here.

Messrs. Lewis and Co., Southgate, staged an attractive group, in which there were several conspicuously fine forms of *Cattleya Mossiae* and *C. Mendeli*, the former comprising several remarkable varieties. *Laelia purpurata* here was again very good. *Odontoglossum vexillarium*, *O. crispum*, *O. cirrhosum*, and *O. citrosimum* magnificent, with extra large flowers, were all included. *Oncidium ampliatum majus*, *O. cornigerum*, and other species were staged here. *Cypripedium caudatum*; *Chysis braetescens*; *Odontoglossum Pescatorei*, an extra fine branching spike, densely flowered; and the old *Dendrobium Pierardi* were all in fine character.

Messrs. Backhouse and Sons showed a beautiful assortment of *Odontoglossum crispum* mixed with small, well-grown plants of *Gleichenias* in variety, the two producing a beautiful effect.

#### ROSES.

These were one of the features of the show, the best display being made by Messrs. W. Paul and Son, of Waltham Cross, whose fine group comprised the best varieties in nearly all sections, in standard and dwarf plants. Among the former we noted W. A. Richardson, Mme. Chedane Guinoisseau, Claire Jacquier, a fine pyramid of flowers, Corinna, Mme. de Watteville, Bouquet d'Or, Mrs. John Laing, Niphotos, and Perle des Jardins. The effect of these mixed with dwarf plants is greatly superior to that of the old banks of specimen plants that used to be shown. In dwarfs, the following were all noteworthy for an abundance of fine flowers: *Violette Bouyer*, *White Lady*, *Gustave Piganeau*, *Caroline Testout*, *Ella Gordon*, *Danmark*, *Victor Hngo*, *Star of Waltham*, *Mme. Fanny de Forest*, a free and little-known white Rose, *Gloire Lyonnaise*, *Ulrich Brunner*, *Queen of Queens*, *A. K. Williams*, *Mme. Lacharme* and *Mme. Montet*. Cut Roses in quantity made a margin to the group—*Gustave Regis*, *l'Idéal*,

Beauty of Waltham, Queen Mab, Sylph, and Anna Ollivier in lovely colour, all admirable. Messrs. Charles Turner and Son, of Slough, also had a very fine group of Roses, showing immense, profusely-flowered specimens of some of the older kinds, as Comtesse de Serenye, Juno, a pretty bright pink kind, and Mme. Lacharme. Other good kinds in standard and dwarf plants were Mrs. John Laing, Camille Bernardin, Mrs. Paul, Margaret Dickson, La France, Celine Forestier, Maréchal Niel, Edith Gifford, Souvenir de S. A. Prince, with many plants of Crimson Rambler covered with bright clusters of flowers. Messrs. Paul and Son, also exhibited Roses largely, some of their specimens of fine size, but wanting a little more time to develop their flowers. The best were Paul's Early Blush, William Warden, La France, with Elise Fugier and Souvenir de S. A. Prince among Teas, and Crimson Rambler and Paul's Single Carmine, in full flower. Messrs. Jackman and Sons, of Woking, showed Roses in fine form, including specimen plants of some of the oldest and sweetest kinds covered with flowers. The best were Mme. Lacharme, Celine Forestier, Anna Alexieff, Duchesse de Morny, Comtesse de Serenye, John Hopper, and Alfred Colomb, all sweet and welcome. Mr. F. Cant, of Colchester, showed pot Roses well in smaller plants, but the individual flowers of high quality, especially in the varieties Mrs. Paul, Merveille de Lyon, Caroline Testout, Ulrich Brunner, Margaret Dickson, Marchioness of Londonderry, with the Teas Niphotos and Souvenir d'un Ami, the group edged with the pretty little Polyanthas Little Dot and Anna Maria de Montravel. Mr. W. Rumsey, Waltham Cross, showed Roses largely, his best being Heinrich Schultheis, large bright rose, Magna Charta, Celine Forestier, Mme. Gabriel Luizet, Souvenir de S. A. Prince, with cut flowers in quantity of Maréchal Niel and Niphotos. Mr. G. Mount, of Canterbury, showed cut Roses, but varied the conventional method by setting up the flowers in alternative boxes on a much greater length of stem. It involves the sacrifice of some wood, but the result is a great gain artistically. The varieties set up in this charming way were Catherine Mermet and Mme. Gabriel Luizet. Other H.P.'s and Teas were well shown by the same exhibitor.

#### STOVE AND GREENHOUSE PLANTS.

Messrs. Sander and Co., St. Albans, had a group of new and rare plants, some of striking beauty, including *Sarracenia flava* and *S. flava picta*, represented by two very fine specimens; *Darlingtonia californica*, large and well grown; *Arisema fibratum*, with grey and purple spathe and a curious long drooping spadix, fringed with dark hairs; *Dracaena Godseffiana*, a distinct and beautiful species, quite unlike any other kind, of tall, branching growth, with long pinnate leaves, the leaflets ovate and green, profusely mottled with pale yellow; *Eriocnema Sanderæ*, with large, broad, corrugated leaves of a deep olive-green colour, shaded with brown and covered with hairs, silvery lines following the venation of the leaf; and *Heliconia illustris rubricaulis*, magnificent in its colour of stem and leaf, the leaf-stalks red, the blades reddish green, spotted and veined in an indescribable way. In habit of growth this *Heliconia* resembles a *Canna*, but in leaf beauty it is one of the most remarkable introductions of recent years. *Dracaena Sanderiana*, with white and green striped leaves and of tall, graceful growth; *Maranta Sanderiana*, broad, deep green leaves, with light-coloured stripes; *Bentineria Nicobarica*, a handsome new and quite distinct Palm; *Hemantus Kalbreyeri*, the true form, with crimson flowers; *Asparagus albanensis*, a light, graceful variety; *Anthurium albanense*, with deep-coloured spathe; *Sonerila* in variety and *Begonia Rex* were noteworthy. Messrs. J. Veitch and Sons showed an extensive lot of hybrid *Streptocarpus* in many shades of colour, from pure white to deep violet-purple, also another race of hybrids from *S. gratus*, of quite distinct character both in leaf growth and flowers. The main leaf of each plant is long and broad, whilst the flowers are more numerous in the truss,

and differ in shape and disposition, resembling those of a *Tydea*, whilst they are inclined to be erect. They embrace soft subdued shades of colour, too, from light rosy purple to reddish purple, but are most effective owing to their profuse bloom. *Phyllocactuses*, also from Messrs. Veitch, were charming in new and bright colours, the best being *Agatha*, soft blush; *Rowena*, deep crimson; *Gordonianus*, light salmon; *Jessica*, rose; *Excellent*, orange-red. *Gloxinias* from the same firm were good, especially Mrs. Donaldson, crimson self; *Ismene*, white with red spots; and *Brilliant*, a most interesting variety, the result of crossing a *Gloxinia* and *Gesnera pyramidalis*, the flowers in shape resembling those of a *Gesnera* and of a brilliant crimson colour. Messrs. Sutton and Sons, of Reading, showed magnificent *Calecolarias*, the plants of large size, profusely bloomed, the flowers fine and very varied in colour. Special mention must be made of the variety named *Cloth of Gold*, with self flowers of pure rich yellow colour. *Princess of Wales* when opening has a spotted flower, but it also becomes a true self of a distinct pale salmon shade. *Saintpaulia ionantha* has never been shown finer than it was on this occasion by Messrs. Sutton, and we noticed some variation in colour from light to deep violet purple. Their *Gloxinias* were also first-rate, large flowers in bright clear colours. Messrs. Hugh Low and Co., of Clapton, had a fine group, their *Caladiums* bright in colour—*Charlemagne*, with red veins on a white ground; Mrs. Harry Veitch, crimson leaf; and *Queen of the Isles*, dark red-veined leaf, margined with white, with deep green edges, especially distinct. *Cannas* in this group were good, the best being *Charles Harrison*, self crimson; *Charles van Geert*, soft orange-red; *L. E. Bally*, yellow, spotted with red; and *Alphonse Bouvier*. The best group of *Caladiums* was that from Messrs. J. Peed and Sons, the plants being noteworthy for their bright colours, and many most charming varieties were shown. *Rose Laing*, with white leaf, suffused with pale pink; *John Peed*, deep crimson centre, green edges; *Ibis Rouge*, red veins, leaf red and white; *Ibis Rose*, soft delicate rosy colour; *Raymond Lemoine*, red centre with white margin; *Michel Buehner*, entirely red, were all first-rate, besides many others that space will not permit of mentioning. Messrs. J. Veitch and Sons also had a group of *Caladiums*, some of the plants fine specimens with enormous leaves, among them *Gaspard Crayer*, *Duchess of York*, soft red, *Lord Derby*, *Henry Irving*, *G. Berger*, Mrs. H. Veitch, and *Cardinal* specially worthy of note. Mr. Hunt, gardener to Mr. P. Ralli, Ashted Park, also showed a fine group of well-grown bright-coloured *Caladiums*, and Mr. W. Iector showed a small group. *Begonias*, always a feature, were represented by several large groups, the best being that from Mr. Ware, of Tottenham, the arrangement lightened by using a few small Palms and Ferns, adding to the effect and somewhat relieving the flatness of this flower when arranged in a solid bank without other plants. The doubles and singles were about equally represented, the best of the doubles being *Maid of Kent*, rosy cerise; *Snowdon*, white; *Beauty of Belgrove*, salmon-rose; *Duchess of Teek*, pale yellow; *Victory*, scarlet; *S. Pope*, cream-white, with *Picotée* edging of bright rose; and *White Camellia*. The finest singles were *Challenger*, crimson; *Lord Byron*, light red, white centre; *Zanda*, soft cerise; *Violacea*, deep crimson; *Empress of India*, rosy red, white centre, with crimped petals; and *Moravia*. Messrs. H. Cannell and Sons, of Swanley, also had a large group, the best being Mrs. Phipps, salmon-rose; *Lord Rosebery*; *Lady Cook*, soft rose; and *Mary Cannell*, bright rose—all double; and *Primrose Queen*, pale primrose; *Miss Clark*, white centre, edged and suffused with red; and *Lady Henry Grosvenor*—all first-rate single kinds. *Gloxinias* from the same exhibitor were fine, especially *Evantina*, with white throat and lavender-blue petals; *W. Marshall*, deep violet-purple; *Prince of Wales*, brilliant crimson self; *Princess of Wales*, red, edged with white; and *Byblis*, pure white.

*Cannas* in this exhibit were noteworthy, the best being *Due do Mortmart* and *Mme. Crozy*. A well-arranged group of *Begonias* was shown by Mr. H. J. Jones, Ryecroft Nursery, Lewisham, the kinds single, with fine flowers in telling colours. *Pelargoniums* of the decorative class from Mr. Jones were very good, the plants medium specimens of an informal character and most profusely bloomed. Some lovely distinct new kinds were shown that we need not enlarge upon here, and the same remark applies to the Ivy-leaved varieties. *Pelargoniums* from Mr. Charles Turner were shown in large specimens of the usual formal type, the plants all profusely flowered; *Duke of Norfolk*, red; *Statesman*, soft rose, with dark blotches; *Gold Mine*, light scarlet, with white throat; *Lizzie Coombs*, *Orient* and *Duchess of York*, among large-flowered varieties, and *Lady Carrington*, soft pink; the *Shah* and *Delicatum* in fancy kinds being a selection of the finest. Mr. J. Prewett, Hammersmith, showed *Pelargonium Duchess of York*, a pretty tricolor-leaved variety, and *Pelargonium Glory of the West* from Mr. Godfrey, Exmouth, is a free-flowering decorative variety of cerise-rose colour. *Calecolarias* from Mr. James, Woodside, Farnham Royal, made a telling group, these, like his famous strain of *Cinerarias*, being characterised by their dwarf habit and rich colours. A good group of flowering and fine-foliaged plants was shown by Mr. H. B. May, of Edmonton, notable plants being *Adiantum Lambertianum*, a fine specimen of this graceful Maiden-hair; *Asplenium caudatum*, with hanging fronds quite 4 feet in length; *Platycerium grande*, a large piece; *Coleus Crimson Gem*, with dark crimson self-coloured leaves, and first rate *Gloxinias* in white, purple and crimson-shades. A bouquet of *Tropaeolum Coolgardie* that received an award of merit at a previous meeting this year also figured in this group. Messrs. Balehin and Sons, of Hassocks, showed a beautiful group of hard-wooded plants, the centre of attraction being the blue *Leschenaultia biloba major*, whilst *Erica coccinea major*, *E. perspicua nana*, *Boronia heterophylla* and *B. serrulata* were hardly less attractive, being little grown at the present day. Mr. W. Iector, of Putney, had a fine group of Palms and *Lilium longiflorum*, with a pretty margin of small *Dracanas*, *Pandanus*, *Ferns*, *Ericas*, and *Caladiums*. Messrs. W. Cutbush and Son, of Highgate, had a group of Palms, large *Azalea mollis*, *Hydrangeas*, *Carnations* and *Leschenaultia*. An effective group of Palms, *Crotons*, *Dracanas* and *Ferns* in variety, prettily margined with *Tradescantias*, *Panicums*, *Fittionias* and *Selaginellas*, was also arranged by Messrs. Will and Segar. Mr. Jennings, of Ascott Gardens, Leighton Buzzard, showed a group of Malmaison *Carnations* with flowers of the same large size and high quality as on former occasions. *Carnation Uriah Pike* was represented by two large groups, one from Mr. G. May, of Teddington, and the other from Mr. J. Pike, of Acton. Mr. Turner showed a group of specimen *Azaleas* in profuse flower, and Messrs. Collins and Gabriel sent plants of a yellow *Carnation*. A fine group of *Clematises* came from Messrs. R. Smith and Co., of Worcester, the best varieties being *Pride of Worcester*, mauve-blue, *Madame van Houtte*, pure white, and *Lady Caroline Neville* in single-flowered kinds, and *Belle of Woking*, double. Messrs. Jackman also had an interesting lot of their new race of *C. coccinea* hybrids, the most distinct being *Sir Trevor Lawrence*, crimson, *Countess of Onslow*, which was certificated last year, and *Duchess of York*, pale blush, a lovely kind. A pretty group of *Ferns*, *Palms* and *Amaryllises* was shown by Mr. Perkins, gardener to the Hon. W. F. D. Smith, Greenlands, Henley-on-Thames, and Mr. J. T. Bennett-Poë showed good specimens of *Streptosolen Jamesoni*. Mr. Empson, gardener to Mrs. Wingfield, Amptill House, Beds, showed *Anthurium Andreamum*, *Dracaena australis*, a pretty variegated form, and *D. Doucetti*, also variegated. Early flowering and fine-leaved shrubs were well shown in a grand group from Messrs. J. Veitch and Sons, many excellent things being present that space will not permit of enumerating.

Messrs. Fromow and Sons, of Chiswick, showed a fine group of finely-coloured-leaved Maples and other shrubs. Messrs. W. Paul and Son, of Waltham Cross, sent an interesting group of shrubs in which Lilacs were a fine feature, and Messrs. J. Cheal and Sons, of Crawley, sent an interesting lot of seasonable shrubs. Rhododendrons in many choice varieties made a brilliant group shown by Mr. John Waterer, of Bagshot, and Japanese Maples in variety were also largely shown. Mr. J. H. Johnston, Bignor Park, Pulborough, sent cut specimens of Rhododendrons in variety.

#### FERNS.

These made a pretty display welcome to turn to after the gay masses of plants in flower. Messrs. W. and J. Birkenhead were prominent exhibitors, with a large and varied group of tender and hardy sorts. Some distinct Adiantums were *A. speciosum*, with long arching handsome fronds, *A. monochlamys*, dwarf and graceful, and *A. palmatum*, of erect growth. *Davallia fijiensis elegans* was shown in fine specimens. *Hymenodium erinitum* is a curious species, with broad leaves covered with dark bristles, and *Drynaria musafolia*, although a Fern, has miniature Musa-like leaves, nearly 18 inches long and 4 inches broad. Among hardy kinds, *Osmunda cinnamomea*, *O. Claytoniana*, and *Oncoclea sensibilis* were good, with crested and other forms in variety, but considerable space would be needed to do justice to this comprehensive exhibit. Messrs. Backhouse and Sons, of York, with an interesting exhibit of Filmy Ferns in cases, deserve commendation for showing these most charming Ferns that command much admiration, though few grow them. *Trichomanes reniforme* was a fine piece; *T. meifolium*, graceful, with long fronds; and *T. exsectum*, even more elegant with its finely-cut fronds. *Hymenophyllum* in variety were also represented by many large healthy specimens. A good group of handsome Ferns was also sent by Messrs. J. Veitch and Sons, the most noteworthy kinds being *Adiantum Lambertianum*, an exceedingly graceful Maiden-hair; *A. Weigandi*, with large upright, deep green fronds; *A. Legrandi*, a fine plant with close, compact fronds; and *A. macrophyllum albo-striatum*, in which the pinnae on old fronds are white-striped, whilst the young fronds are of a light red tint, most charming in effect. Other rare, but distinct sorts were *Hemionitis cordata*, which has an entire heart-shaped pointed frond; *Scelopendrium seulariforme*, of dwarf growth, the fronds curiously wrinkled on their edges; *Osmunda japonica corymbifera*, a pretty crested form; *Pteris longifolia Mariess*, most distinct, with long pinnules; *Hymenodium erinitum*, already described; and *Actinopteris radiata*, with pinnules like blades of Grass radiating from the top of the stem.

#### HARDY AND CUT FLOWERS.

These took up a great amount of space, and altogether made a comprehensive display, showing abundantly the wealth of fine flowers that may be had in the outdoor garden at the present time. Mr. T. S. Ware, of Tottenham, had a prominent group, showing specimens in large pots and pans, so that the full beauty of the plants and their growth can be seen. Tree Pæonies, Irises, Spiræas, Globe Flowers, Phloxes, and hardy Cypripediums were in good form. Messrs. W. Cutbush and Son, of Highgate, had a prettily arranged group of Irises, Pæonies, *Heuchera sanguinea*, Globe Flowers, Lupins, and Day Lilies, with a mossy foreground, in which nestled many little alpines. Mr. J. R. Box, of Croydon, showed a nice group, having *Heuchera sanguinea* in abundance, with Pæonies, *Choisya ternata*, *Iris florentina*, *Polemoniums*, *Centaureas*, and Spanish Scillas in large bunches; also Carnations in several kinds. Mr. Ludhams, of Southampton, showed a fine group of characteristic freshness and variety, the best flowers being *Aquilegas* in many forms, *Camassias*, *Aponogon distachyon*, Globe Flowers, Lupins, *Primula japonica*, and *P. Sieboldi*. Messrs. Kelway and Son made a fine display, Tree Pæonies being the chief flower, of which they showed some lovely new kinds, so

beautiful and important that they will be noted elsewhere. *Iris florentina*, *I. germanica* in variety, *Aquilegia corulea*, *Pyrethrums*, new single kinds in bright crimson, soft rose, and pure white colours, and cut spikes of good *Cannas* completed this group. Messrs. Barr and Son showed Tulips in quantity of all the late flowering types, single Pæonies of great beauty, fine garden flowers that more should grow; *Iris germanica* in several fine kinds, *Primula Sieboldi* in various distinct colours, and large bunches of *Thalictrums*, *Camassias*, *Geums*, Day Lilies and Spanish Bluebells. Mr. M. Priehard, of Christchurch, Hants, showed a group of the best hardy flowers in season, tastefully arranged with rare and lovely alpine plants in flower along the margin. The finest flowers were Globe Flowers in bright colours, Phloxes, *Iris sibirica*, *Verbascum phœniceum*, *Camassias*, Day Lilies and Cypripediums. A miniature rock garden, arranged by Messrs. Backhouse, of York, was literally covered with alpine gems in flower, of which but a tithe can be mentioned, those of special note being *Gentiana verna*, *Ranunculus cortusifolius* and *R. glacialis*, *Dianthus callizonus* and *D. alpinus*, *Symphandra Wanneri*, *Silene acaulis muscoides*, *Delphinium nudicaule*, *Androsace coronopifolia*, and *Arenaria longifolia*, a most distinct species, with grassy leaves and heads of white flowers on stems 9 inches in length. Messrs. Paul and Son, Cheshunt, also showed alpines arranged on a rock garden of shelves or ledges, masses of *Aubrietas*, Phloxes, *Androsaces*, *Saxifrages* and *Primulas* being prominent; cut hardy flowers in quantity came from the same exhibitors. Dr. Wallis, of Colchester, was the only exhibitor of the charming *Calceoliti*, showing several handsome kinds; also *Camassia Cusicki*, which has a tall handsome spike of pale blue flowers, and *Iris germanica* in several fine forms, one of the best being Princess of Wales. Messrs. J. Veitch and Sons showed bunches of many things, the most interesting being *Dodecatheons* in charming and distinct varieties, Spanish Scillas in many coloured kinds, and the lovely *Hyacinthus amethystinus*. Messrs. J. Carter and Co. showed Pæonies, *Doronicums*, single and double Tulips, *Primula Sieboldi* in variety, and good tufted Pansies in pans. Mr. S. Pye, Catterall, Garstang, showed tufted Pansies in large variety, the varieties of Dr. Stuart's raising, in pure and lovely colours, being a feature of this exhibit. Messrs. Dobbie and Co., of Rothesay, also had a fine exhibit of tufted Pansies, comprising all the best known kinds. Messrs. Perkins and Sons, of Coventry, exhibited floral designs and bouquets in their best style, and Messrs. B. S. Williams and Son, of Holloway, showed graceful baskets, bouquets and sprays. Mr. J. R. Chard, of Stoke Newington, made a prominent display with his Arcadian decorations in great variety of design, gracefully arranged with flowers and foliage. The Horticultural College, Swanley, arranged a table charming in its simple beauty, sprays of Smilax and Roses only being used. Bouquets were also shown. Mr. J. Prewett, Swiss Nursery, Hammersmith, showed a pretty rustic design in table decoration. Mr. L. H. Calcutt, of Stoke Newington, had a graceful lot of arches, bouquets and baskets, and Messrs. Phelps and Co., of Cardiff, showed fine bouquets of Roses and Orchids.

Want of space compels us to leave over the report of the fruit and vegetables as well as that of the Tulip show. A list of the awards will be found in our advertisement columns.

**New Tree Pæonies.**—Some notable new Tree Pæonies were shown at the Temple by Messrs. Kelway: the flowers of large size, single or semi-double, and most graceful as compared with those of the full double varieties. The best were Princess of Wales, which has an immense flower of the purest white colour; Duchess of Teck, white, with long, narrow petals; and a white variety, with a blush tinge on the edges of the petals and a suffusion of the same at their base. Lord Iveagh, which received an award of merit,

has a distinct flower of large size, the petals wedge-shaped, narrowing at the base, its colour bright cerise-red. Mrs. J. W. Simcox, salmon-rose; Mr. McMillan, rosy-blush; and Sarah Bernhardt, flesh pink, are all equally beautiful. Such noble flowers ought soon to find a prominent place in many gardens.

**The weather in West Herts.**—There was a very marked contrast between the weather of the past week and that of the preceding one, the latter having been singularly warm and bright, while throughout most of the former the temperature remained unseasonably low and the sky obscured by cloud. The great change in temperature is shown very clearly by the readings of the ground thermometers. On the 14th inst. the temperature at 2 feet deep stood at 58°, and at 1 foot deep at 63°, but only six days later the reading at 2 feet had fallen to 53°, and at 1 foot to 52°. These are great changes in so short a time. A welcome rain of nearly half an inch came on the 17th inst., but previous to this no rain worth mentioning had fallen for three weeks.—E. M., *Berkhamsted*.

## PUBLIC GARDENS.

**New recreation ground for Maidstone.**—The new recreation ground at Maidstone was yesterday afternoon opened by Lord Harris. The site, which covers nearly 20 acres, was the gift of Mr. Balston, of Maidstone (the late High Sheriff for Kent), and its conversion into a recreation ground has cost nearly £10,000. A considerable portion of the ground has been set apart for cricket and football, while a cycling track, believed to be the largest in England, has also been formed.

**Destroying crickets.**—Will any reader tell me how to get rid of crickets in a dwelling house? I have tried insect powder, but find no dead crickets. Cockroaches readily take the powder and it soon kills them.—OLD READER.

\* \* I have twice cleared houses of crickets by blowing insect powder into the holes and cracks where they lived near the kitchen fire. A correspondent some time ago who was much troubled with these insects in one of his glass houses let the fire out for three days, and kept everything near where the crickets sheltered themselves saturated with water. This completely disconcerted them, as they love warmth and dryness. Many crickets during the late frost must have had a very bad time of it.—G. S. S.

#### BOOKS RECEIVED.

"Flowering Plants and Ferns of New South Wales," Part 1.  
"List of Exotic Trees and Shrubs affected by Australian Loranthus and Viscum."  
"Vine Culture under Glass," by J. R. Pearson. Revised and edited by C. E. Pearson. 6th edition. 1s. T. Forman and Sons, Nottingham.

**Names of plants.**—S. N. T.—1, *Keria japonica variegata*; 2, *Piptanthus nepalensis*; 3, *Polemonium coruleum*; 4, *Potentilla* var.; 5, *Geranium macrorrhizon*.—*John Bennett*.—Good forms of *Odontoglossum crispum*.—*H. J. Scammell*.—*Pyrus aria*.—*J. J. W.*.—*Dendrobium bellatulum*.—*J. E.*.—Impossible to name from such a dried-up scrap.—*R. P. Brotherston*.—*Aerides Fieldingi*.—*C. Russell*.—A fasciated flower. It frequently occurs.—*G. P. P.*.—1, *Caragana arborescens*; 2, *Kalmia rosea*; 3, *Calycanthus floridus*; 4, *Cornus sibirica variegata*; 5, *Ribes aureum*; 6, *Philadelphus microphyllus*.—*J. Riddell*.—Both forms of *Odontoglossum crispum*. The *Anthurium* is a remarkably fine form, well worth keeping.—*C. Blake*.—*Lonicera tatarica*.

**The Wild Garden:** or, the Naturalisation and Natural Grouping of Hardy Exotic Plants, with a chapter on the Garden of British Wild Flowers. Fourth edition, with wood engravings from drawings by Alfred Parsons, revised and enlarged. 1cmj 8vo, linen cloth. Price 12s.; well bound in half morocco, 18s. Through all booksellers.

"This is an Art  
Which does mend Nature; change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHARD AND FRUIT GARDEN.

### GRAPE GROS COLMAN.

WHATEVER may be said or thought about the flavour of this variety, there is no gainsaying the fact of its being the most profitable late Grape in cultivation. It is the immense berries that seem to please most buyers, and the latter are not, as a rule, very fastidious as to colour so long as it is nearer black than red. Instead of extra fine Muscats fetching double the price of Gros Colman, the reverse is often the case, superior bunches of the latter sometimes realising as much as 6s. per lb., when from 3s. to 4s. only are forthcoming for Muscats. One friend of mine started growing Muscat of Alexandria extensively for the market under the impression there was "money to be made at it," only to find that he had far better have substituted Gros Colman. The Channel Island growers were not particularly slow in finding out what they ought to grow in the place of Black Hamburgh when the prices for the latter fell to such a very low figure, but, unfortunately for them, they are very rigidly protected, and the Phylloxera scare led to laws being made strictly prohibiting the introduction of Vines, cuttings, or eyes. As might be expected, this did not wholly cut off supplies, and at the risk of a fine of £20 several growers contrived to procure enough cuttings of ripe wood to inarch on to their Black Hamburgh stocks and a good start was made. On p. 277 "G. C. R." drew attention to the successful culture of Gros Colman in the neighbourhood of Bath and elsewhere, but omitted mentioning the fine bunches annually shown at Bath and Bristol by Mr. W. Nash, Badminton Gardens, Chippenham. Mr. Nash's bunches, never very large, are remarkable for their good form and the size and finish of the berries. A single large shoulder would appear perfectly characteristic, but when the bunch proper is large enough it is well to dispense with great shoulders altogether. Well-established Vines are capable of producing a greater weight of fruit without the strain injuriously affecting them than is the case with any other variety that can be mentioned, but private growers are not under any obligation to crop unduly heavy, and ought not to do so if they are anxious to have the berries large and perfectly coloured. In particular ought great clumsy bunches to be avoided. Nearly every strong lateral gives two or three "shows," and if that nearest the old wood is coarse and ugly, remove it in favour of the next, which usually is, or can be made of better form. In order to have very large berries the flowers must be strong and the set perfect, at least four stamens or seeds forming in each. There must be no delay in removing superfluous laterals or in stopping those reserved at the second joint beyond the bunch saved, the aim being to admit plenty of light to the bunches long before they are in flower, as well as during the flowering period, a smart tap towards noon each day doing the rest. Thinning the berries cannot well be started too soon. Experts do most of theirs while yet the berries are no larger than the seed of Sweet Peas, and some even go the length of commencing thinning the flowers before they have opened. It is

the central berries in each sub-division of bunch that are or will be the largest, these also having the strongest foot-stalks, and few other than these ought to be left. A well-thinned bunch usually appears over-thinned to the uninitiated, but if two berries are left where one is ample, that means the removal of what would have developed into the finest berries as well as another turn at thinning later on. When berries have to be cut out "at the last minute," that is to say, when they are beginning to press against each other, a very steady hand indeed is required, or otherwise those reserved will be badly disfigured. The rule then ought to be, "thin early and thin severely." If the reduction of the number of bunches is not completed before the thinning is done, it should take place soon afterwards, not waiting till colouring commences or till the grower gets frightened at having left a far greater weight of fruit hanging than intended. I have seen whole barrow-loads of bunches cut from over-cropped Vines when it was far too late to greatly benefit the rest by their removal. Be content with handsome medium-sized bunches, alternating these up the rod, one on every second lateral each side. Quite the reddest ripe berries I have seen of Gros Colman were produced by strong rods inarched on to a large Muscat of Alexandria Vine. Each year these rods gave grand bunches and berries of the largest size, but never once was a bunch cut that would have taken a prize at an average autumn show. It was not the fault of the stock, but rather owing to the temperature of the house that the colouring was so bad. High temperatures evidently favour the swelling of the berries to a great size and perfect ripening in the case of white Muscats, but are altogether unfavourable to the colouring of Gros Colman. Those red berries were of excellent quality and superior to many blue-black berries I have tasted, and another instance is afforded in support of the theory that neither a good nor bad colour is any criterion of quality. At Fordingbridge Mr. Castle used to grow extra heavy crops of Gros Colman, and which were of excellent quality, but the colour was scarcely up to exhibition form, nor ought it to be expected when the crops are exceptionally heavy. I hold that the colouring period in the case of the Grape under notice extends, or should extend, over a greater length of time than is required for any other variety in cultivation. Some of the best Gros Colman I ever grew commenced colouring late in August, and an improvement in the colour was observable as late as the end of October. They were not hurried, as may be imagined, but enough fire-heat was kept up to maintain a good circulation of air both by night and day. One essential to perfect colouring is healthy foliage. There must be no scalding, owing to imperfect ventilation, nor no red spider allowed to gain a foothold. Although the leaves are usually large and stout, they appear to be very liable to burning, and modern vineries with a minimum amount of woodwork and a maximum quantity of glass, in large squares, would seem to be less suited to the variety than are the more old-fashioned structures. So much importance do I attach to the preservation of the primary or first-formed leaves, that I strongly advocate lightly shading the roof where the foliage is greatly exposed to all the sunshine going. A fish-net hung slackly over the roof is sufficient, or a very light shading of lime water may be sprayed over the glass with a syringe as often as need be.

What "G. C. R." advances as to the possibility of over-feeding this Grape when rooting in a heavy retentive soil holds good, I think, in

the case of Grapes generally. There ought to be no fixed times for watering, or rather there should be no general rule laid down. During very hot weather some borders—though, luckily, few in number—require to be watered three times a week. Just now it is my lot to have to do with a soil that must be watered very frequently, and it seems to suit Gros Colman remarkably well. In another vinery that I had charge of for many years a good watering once a fortnight was sufficient during hot weather, and much less often at other times. Cultivators ought always to be guided by the state of their borders. These can easily be probed to a good depth without damaging many roots, and water should be given when the soil is approaching dryness—not much either before or after. It is not such a great amount that is needed if the soil is caught at the right time, but wait till it becomes dry and crumbling, and the chances are one heavy watering will not be sufficient to properly remoisten it. Too much manure, that is to say, too much at one time, is a mistake, not merely in the case of Gros Colman, but with all other Grapes. The roots cannot absorb large quantities, and may easily be injured by an overdose. At the same time, I agree with "G. C. R." that Gros Colman will not thrive in an over-rich soil that may yet be not altogether unsuited to Alicante, Lady Downe's, and such like. Some twelve years ago it fell to my lot to plant a new vinery. The border was formed inside the house, of rather heavy soil, and early in the winter, in readiness for newly-raised Vines that would be large enough to plant in May. During part of the winter and the early spring months a temporary staging was fixed along the front of this house for a rather large batch of Cinerarias. The latter were very highly fed for several weeks, and naturally the drainage from these enriched the border underneath. Out of a collection of the best late Grapes planted in this soil, all grew well but Gros Colman, and this variety failed badly in each instance, to the extent of being a disfigurement to the house for two years. What it seems to revel in is a fresh supply of light loamy compost every second year.

W. IGGULDEN.

**Strawberries and drought.**—I have never proved the value of an autumn mulch on Strawberry beds on light soil more than this season. For several weeks bright sun was accompanied by high parching winds, which drew all the surface moisture out of the ground, so much so indeed, that Strawberry plants grown expressly for runners by the margins of walks and unmulched showed signs of distress. On examining the bearing beds, which were well mulched in December with short litter from the pig yard, the same being well-soaked with urine, I find that the surface soil is as moist and cool as it was when the mulch was applied. Had it not been for this mulch I am confident that our plants would have suffered much and the crop proportionally. Of course, I would not advocate the autumn mulch on heavy, retentive soils, rather waiting till early spring, but I am sure that if applied earlier than is the rule with many, crops would be better and spider less troublesome.—C. N.

**Pruning standard Apple trees.**—The soil at Normansfield, Hampton Wick, is generally of a very light, porous, sandy nature. Perhaps it is for this reason that the rule prevails of somewhat hard pruning or spurring the branches of standard Apple trees. These trees, some twelve to fourteen years planted, have very stout, clean stems, and in all cases the heads are restricted to long stout branches that are treated as cordons, for every side shoot is rigidly cut off. Cleaner or more healthy trees, and there are many of them, could not be found, and so far as the pre-

sent season is concerned, they exhibit promise of a grand crop of fruit. Lord Sutfield is on this soil and under this form of treatment wonderfully robust and healthy, whilst Blenheim Pippin does not seem to grow very rampantly. Cox's Orange Pippin and King of the Pippins are also in very fine condition. It is possible that in strong, retentive soil this form of pruning would prove too drastic and result in the constant reproduction of wood. Here the pruning thus given seems to create an admirable balance as between root capacity and head. It perhaps serves to show that it is not easy to lay down any hard-and-fast rule to serve for all soils, and only personal experience will enable the grower to do the right thing according to surroundings. On sand, Mr. Salter, at Woodhatch, Reigate, prunes his dwarf or bush trees in a similar fashion. Just, indeed, as Mr. Molyneux on the Swanmore chalk prunes his Red Currants, the long branches in each case being close spurred, yet in both cases fine crops are produced. No doubt the method, whilst not so repressive of growth as is sometimes seen in gardens, enables the tree to obtain plenty of light and air, and that is matter of the highest moment.—A. D.

**Disbudding Peach trees.**—Doubtless this is often unduly postponed; consequently the crop of fruit is much affected. There is with many a reticence in commencing to reduce the shoots as soon as the fruit is well set. In the meantime the growth on vigorous trees makes great headway, monopolising the bulk of the sap and causing many of the fruit to fall. A second evil is that the tree receives a considerable check when so treated, which is also sufficient to cause the fruit to drop. If piecemeal disbudding is begun very early, commencing at the top of the tree, a secondary reduction may take place in five or six days, and a third and final one before extended shoots have had a chance to rob the fruit of nourishment. If more attention were paid to this important point we should hear less of Peaches failing.—C. H.

#### EFFECTS OF FROST ON FRUIT TREES.

It is worthy of note how the frost has retarded the flow of sap on some kinds of fruit, and this is particularly noticeable with Plums and Cherries. Last spring, and also in 1893, vegetation of all kinds was very forward; the blossom of all kinds of hardy fruit—with the exception of the Apple—had faded and gone long before this date (May 10). Last season, Plums, Pears and Cherries were well advanced by this time; this year, however, the order of things is reversed. The Apple blossom is fully two days earlier now than it was at the same date last year, as there was scarcely a flower open before the 15th of this month; while this spring all—with the exception of a few of the late-flowering kinds such as Court Pendu Plat, French Crab and Northern Greening—will have shed their petals by that date. It was on May 19 that the cold weather set in last year. The Apple trees were then in full bloom, and as we had such a wet period for the following week or ten days together with cold frosty nights, there was but little chance of the pollen getting dry; hence the cause of the scarcity of fruit. Plum trees here in the open orchard, except the early kinds, are only now in bloom; the same may be said of Green Gages and Damsons. The Cherries in the orchards, too, are still in bloom, thus showing the peculiarity of the season. We have sometimes had the fruit on such trees the size of Peas at the end of April, when the Apple trees have only been showing their buds. Why the frost should have taken more hold on Plums and Cherries it is difficult to explain, and I can only account for it by the wood being injured to such an extent as to prevent the sap flowing. Had it not been for the moist weather we experienced during April many of the trees would have failed to have put forth leaves again. I noticed a large tree which had the bark split from the upper branches to the ground by the frost; this has even now failed to put forth any shoots. So far Black Currants
